
Table 2 Quantitative transmission of *var1* and antibiotic markers in crosses

				% Transmission					
Cross	*ery*^{s} *oli*^{r}*1*	×	*ery*^{r} *oli*^{s}	*ery*^{s}, *oli*^{r}*1*	*ery*^{r}, *oli*^{s}	*var1*^{F}	*var1*^{IF}	*var1*^{IS}	*var1*^{S}
1	F	×	S	53	47	27(53)	30	2	40(47)
2	F	×	IF	60	40	29(60)	71(40)	—	—
3	F	×	IS	62	38	61(62)	—	39(38)	—
4	IF	×	S	52	48	—	51(52)	—	49(48)
5	IS	×	S	43	56	—	—	21(43)	79(56)
6	IF	×	IS	38	62	—	39(38)	39(62)	22

The progeny of crosses described in Fig. 3 were scored for transmission of the *var1*, *ery* and *oli* loci. *Var1* transmission was quantitated according to the protocol described in Fig. 2. In each case, the cross was repeated several times and the values given are means. The expected transmission values for *var1* based on coordinate transmission with the drug markers, are given in parentheses The dash indicates that no *var1* of that type was observed in random diploid progeny.

hand, compared to the transmission of *ery*^{s} and *oli*^{r}*1*, only about one-half of the input F alleles were recovered in the output of the cross. Importantly, this loss could largely be accounted for by the amount of the IF species which occurred in the diploid progeny, suggesting that this new form of *var1* arises chiefly by a gene conversion of the F allele. As the frequency of production of the IS species is less than 2%, it is difficult from this type of experiment to determine whether it also arises by a gene conversion event. Although the transmission of S is within two standard deviations of that of *ery*^{r} and *oli*^{s}, every estimate of S transmission was numerically smaller than that of the drug makers; thus, it is possible that there is some net loss of S so that reciprocal recombination could play a minor part in the generation of non-parental forms of *var1*.

To examine this possibility and to determine whether new forms arise only when parental genomes pair, diploids representing each of the four forms of var1 polypeptide were sporulated and the appropriate mating types and nuclear markers obtained in the haploid products to permit all possible pairwise matings involving the four forms of the var1 polypeptide. In Table 2, cross 2, we see that when F and IF are mated, both *var1* alleles are transmitted non-coordinately with the drug markers; we observed low transmission of F and high transmission of IF. This result helps to explain the frequency of IF production in cross 1 (Table 2), as IF genomes formed in the first round of recombination between parental genomes can pair with F genomes to yield more IF in subsequent pairings.

The results of all the other pairwise crosses are shown in Fig. 3 and Table 2, crosses 3–6. The results were clearcut in that no gene conversion was observed in the crosses F×IS or IF×S, whereas conversion was observed in the crosses IS×S and IF×IS. In the latter two cases, IS was converted to S. Note that in the case of cross 6, the conversion of IS to S represents, insofar as this particular cross is concerned, the formation of a non-parental form of *var1*. This result shows clearly that the gene segments which distinguish IF from IS are non-overlapping and leads to the conclusion that F and S differ from each other in at least two distinct regions.

As indicated above, IS could arise in cross 1 by gene conversion or by crossing-over. If the latter were true, then the frequency of crossing-over within the *var1* gene would be of the order of 2%, that is, the frequency of occurrence of IS in cross 1. This would mean that in cross 6, F should then be present in roughly 2% of the total progeny. To obtain greater sensitivity, we analysed an additional 200 random diploid progeny of cross 6 in 20 pooled groups of 10. Again, no F was detected, suggesting that if there are any F progeny in cross 6, they are produced less frequently than IS in cross 1. These data strongly suggest that in the original F×S cross, IS arises by a gene conversion event, but one less frequent than that responsible for the production of IF.

Non-parental forms of var1 arise by physical exchange of DNA sequences

We next extended our analysis to the segment of mtDNA containing the *var1* gene. As noted above, we have succeeded in locating the *var1* gene to a specific *Hin*cII + *Bam*HI restriction endonuclease fragment, about 2×10^{3} base pairs long located between *ery* and *oli1* (Fig. 1), the absolute size of which is strain dependent and varies according to the size of the var1 polypeptide which it encodes[16] (R.D.V. *et al.*, unpublished data).

We isolated mtDNA from homoplasmic diploid progeny of cross 1 (Table 2) representative of each of the four forms of var1 polypeptide and digested it with *Hin*cII and *Hin*cII + *Bam*HI. As indicated in Fig. 1, *Hin*cII fragment 10 (*Hin*cII-10) contains one *Bam*HI site. The structural gene for var1 polypeptide is contained wholly within the larger *Hin*cII-10 + *Bam*HI fragment[16] (R.D.V. *et al.*, unpublished data). Figure 4 shows representative restriction digests of mtDNA from each of the four diploid clones with the parental and non-parental forms of var1 polypeptide. The gel was electrophoresed long enough to accentuate the difference between the large *Hin*cII-10 + *Bam*HI fragments. The small *Hin*cII-10 + *Bam*HI fragment was run off the gel; its molecular weight has been determined on separate gels run for a shorter time. The data show quite clearly that the large *Bam*HI fragment of *Hin*cII-10 varies in size according to the size of the var1 polypeptide for each strain with a different molecular weight form of the protein.

These results are summarised quantitatively in Table 3, which contains our estimates of the molecular weights in the different strains of the *Hin*cII-10 and *Hin*cII-10 + *Bam*HI fragments. Within experimental error, the sizes of the large *Bam*HI fragment of *Hin*cII-10 in the diploids with the S and F forms of var1 polypeptide are the same as those in the parental haploid strains 5DSS and 195D, respectively. The fragment is larger in IS than in IF strains and both are intermediate in size between the S and F forms. Without exception, therefore, a change in the size of var1 polypeptide is accompanied by a change in the size of the mtDNA fragment containing its structural gene.

We have also analysed mtDNA from progeny of the IS×IF cross where the parental S form is generated (Fig. 3). In this case,

Table 3 Apparent molecular weights of mtDNA fragments from ρ^{+} strains with different *var1* alleles

Strain	*Hin*cII band 10	*Hin*cII band 10 + *Bam*HI	
		Large fragment	Small fragment
5DSS	1.872 ± 0.006	1.438 ± 0.005	0.428 ± 0.001
S	1.842 ± 0.008	1.435 ± 0.007	0.427 ± 0.001
IS	1.842 ± 0.007	1.409 ± 0.009	0.427 ± 0.003
IF	1.813 ± 0.004	1.395 ± 0.007	0.406 ± 0.002
F	1.788 ± 0.009	1.376 ± 0.008	0.405 ± 0.002
195D	1.790 ± 0.008	1.377 ± 0.008	0.406 ± 0.002

mtDNA from ρ^{+} strains 5DSS and 195D and recombinant diploid progeny containing parental (S, F) or non-parental (IS, IF) forms of *var1* polypeptide were analysed as in Fig. 3. Apparent molecular weights of *Hin*cII band 10, or the fragments generated from it by digestion with *Bam*HI, were calculated by comparison with the mobilities of ΦX174-RF DNA fragments (combination of digests with *Hae*II, *Hae*III and *Hpa*II) run in adjacent lanes on slab gels containing 2% agarose. *Hin*cII digests were run for 850–900 V h; *Hin*cII + *Bam*HI digests for 630 V h to measure the small fragment of *Hin*cII band 10, or 850–900 V h to measure the large fragment. The small fragment runs off the gel when maximal separation of the large fragments is obtained. Each value represents the mean of 4–7 independent gel measurements

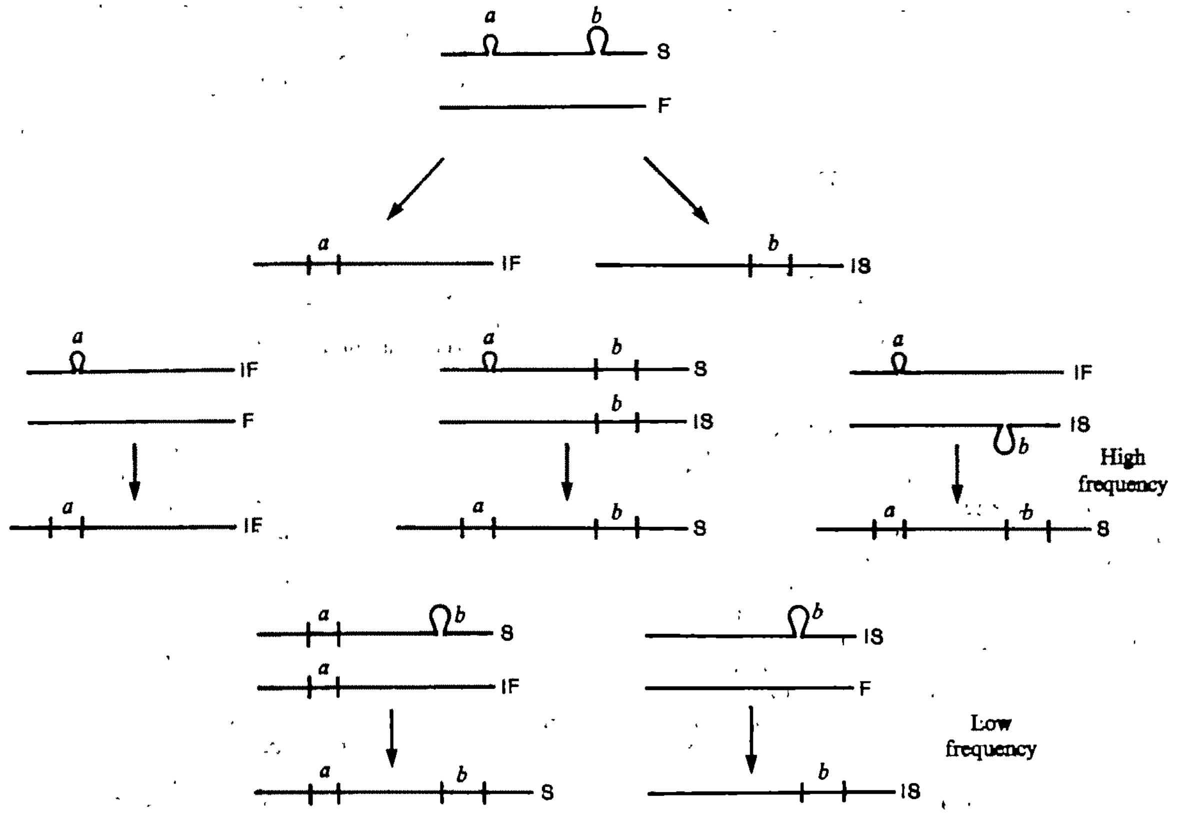

Fig. 5 A model for asymmetric gene conversion at the *var1* locus. Heteroduplex pairing of DNA segments from different *var1* alleles is shown; the positions of the looped out portions are arbitrary.

the size of the *Hin*cII-10+*Bam*HI large fragment in the S diploids issued from this cross is indistinguishable from the parental (5DSS) S form (data not shown). This result, and the fact that the sum of the molecular weight differences between IF, IS and F equals the molecular weight difference between S and F, provide additional support to our conclusion that the regions of difference between IF and IS are non-overlapping.

A model for gene conversion at the *var1* locus

Figure 5 presents a simple scheme fully consistent with the genetic and biochemical data presented here, showing how non-parental forms of the *var1* gene and its product may arise by a process of asymmetric intragenic gene conversion. The model shows two DNA segments or insertions within the S gene which are absent from the F gene. From molecular weight determinations of the parental and non-parental DNA fragments which contain the *var1* gene, we can estimate the lengths of the inserted segments, designated *a* and *b*, to be 36 and 57 base pairs, respectively. Subsequent to heteroduplex formation, these segments are copied independently into the adjacent shorter heteroallele. In the heteroduplex formed between the S and F parental alleles, gene conversion is initiated, perhaps by a single strand break in the (short) strand opposite insertion *a* or *b*, and completed by gap formation and gap-filling repair replication.

Although the two insertions are rather similar in size, our data clearly show that the efficiency of execution (probably of the initial step of the gene conversion event) is much greater for segment *a* than for segment *b*. Not only is IF the most abundant non-parental form of var1 polypeptide issued in the original F×S cross, but also in subsequent backcrosses, in all pairwise matings which could yield a heteroduplex between a strand carrying insertion *a* and one lacking it, the latter is frequently converted to a form containing the *a* insertion. As shown in Figure 5, this may be seen either as the generation of a non-parental form by conversion of one of the parental alleles (such as in the cross IF×IS) or as an unequal transmission of the parental forms (as in the crosses between IF×F and IS×S). On the other hand, backcrosses giving rise to heteroduplex pairs where both strands either contain or lack insertion *a*, although heteroallelic or homoallelic for insertion *b*, show little change in the output of the parental forms. This result is entirely consistent with the observation that the formation of IS, which formally represents the insertion of segment *b* into F in the S×F cross, occurs at a frequency of less than 2%.

The model presented here bears a similarity to the events suggested to occur at the ω locus in heteropolar ($\omega^+ \times \omega^-$) crosses[4,9]. Gene conversion at ω was proposed to be a fundamental feature of mitochondrial transmission genetics[7,8]. It was further suggested that gene conversion might be a general feature of recombination in yeast mtDNA. As is the case at the ω locus, this could be asymmetric, giving rise to a gradient in transmission of markers and grossly unequal numbers of reciprocal recombinant genotypes, or symmetric, in which case coordinate transmission of markers and equal numbers of reciprocal recombinant types would be obtained. Since that time, the analysis of recombination in other regions of the genome failed to reveal additional examples of efficient polar recombination[19,20] so that the events at ω were then viewed as an interesting but special case. We are prompted by our present results to reappraise the relative role of gene conversion as an important feature of the inheritance of mitochondrial genes.

The high frequency of the recombination (gene conversion) events at *var1* described here and those at other regions of the mitochondrial genome, may be explained as a consequence of multiple rounds of recombination in each cell generation[4]. Although that is almost certainly an important property of yeast mitochondrial genetics, it is possible that site-specific recombination may also be involved. In particular, insertions or base sequences at the ends of insertions, may play an important part in mitochondrial recombination. It will be of great interest to learn whether any of these insertions have structural features or base sequences in common and to extend the analysis of the mode of inheritance of other insertions present in mtDNA from various yeast strains to those both larger and smaller than ω^+.

These studies were supported by research grants I-642 from The Robert A. Welch Foundation and NIH-NIGMS grant GM22525 to R.A.B. and GM22837 (subcontracts to P.S.P. and R.A.B.). R.D.V. was a predoctoral trainee supported by training grant HD-00431-HDPB from NIH-NICHHD. We thank Susan Strausberg for discussions.

Mycoplasma capping on lymphocytes

Eric J. Stanbridge & Richard L. Weiss*
Department of Medical Microbiology, University of California, Irvine, College of Medicine, Irvine, California 92717

When mycoplasmas infect lymphocytes they behave as multivalent ligands and cap on the lymphoid cell surface in the absence of added specific antibody. There is an apparent high correlation between mycoplasma capping and blast transformation of the infected lymphocytes. Mycoplasma caps are shed from the surface of cells as an aggregate containing host membrane vesicles. This novel interaction may suggest a physiological role for the phenomenon of capping and may play a part in mycoplasma pathogenesis.

MYCOPLASMAS are extracellular parasites often found in close association with the host cell plasma membrane[1,2]. Their predilection for cell surfaces, especially moist mucosa, is responsible in part for their involvement in pathological states such as chronic respiratory disease, polyarthritis and genital tract infections in many species of animals. Little is known about the specific nature of mycoplasma–host cell interactions either *in vivo*, where the parasites have a fairly strict host species specificity, or *in vitro*. Although specific cell receptors have been described for a few mycoplasma species[3–5], their chemical identities for the most part remain obscure.

We have investigated the nature of these interactions *in vitro* and their possible relevance to the pathogenic consequences of mycoplasma infection[6,7]. We describe here a novel interaction between mycoplasmas and lymphocytes *in vitro*, in which the mycoplasmas behave as multivalent ligands and cap on the surface of infected lymphocytes in the absence of specific antibody.

Mycoplasma infection of an established lymphoblastoid line

Using a strain of *Mycoplasma hyorhinis* adapted to rapid cell colonisation, we infected a mouse lymphoma line, S49 (ref. 8), with mycoplasmas at multiplicities of infection of 1–10 viable organisms per cell. Infected cells were grown in suspension in RPMI medium containing 10% calf serum at 37 °C and then processed for electron microscopy and immunofluorescence 1–2 d after infection.

Viable control and infected cells were stained with fluorescein-conjugated anti-*M. hyorhinis* antiserum diluted in isotonic buffered saline. To compare the distribution of mycoplasmas on the surface of lymphocytes as a function of the lateral mobility of their receptors in the fluid membranes[9–11], antibody staining was carried out at room temperature and 0 °C, and also on lymphocytes poisoned with 5×10^{-3} M sodium azide just before staining. To establish the rate of appearance of caps, S49 cells were stained with fluorescein-conjugated anti-mycoplasma antibody at intervals during a 24-h period after infection with *M. hyorhinis*.

Cells were also fixed in glutaraldehyde and then post-fixed in osmium tetroxide. After dehydration and embedding in resin, thin sections were cut, stained and examined in a Philips 300 electron microscope.

Mycoplasma infection of mouse spleen cells

Spleens were removed from 6–8-week-old BALB/c and *nu*/*nu* (nude) athymic mice, and the spleen cells suspended in RPMI medium containing 10% calf serum. After treatment with ammonium chloride to lyse erythrocytes, the spleen cells were seeded at approximately 5×10^6 per ml in RPMI medium containing 10% calf serum and 5×10^{-5} M 2-mercaptoethanol.

Table 1 Rate of mycoplasma capping on S49 cells

Time after mycoplasma infection (h)	% Cells infected		% Cells capped		% Cells patched	
	PBS	5×10^{-3} M NaN_3	PBS	5×10^{-3} M NaN_3	PBS	5×10^{-3} M NaN_3
1	0.65	0.58	0.0	0.01	0.65	0.57
4	6 40	6.62	2.80	2.65	3 60	3.97
8	17.66	21 20	7.85	8.40	9.81	12 80
16	22.60	22.57	19.20	18.50	3.40	4 07
24	43.35	40 46	38.23	35.80	5.12	4 66

S49 lymphoblastoid cells (3×10^6 cells ml^{-1}) were infected with *M. hyorhinis* at 5×10^7 colony-forming units per ml. At the indicated time intervals cells were washed with phosphate-buffered saline (PBS), stained with fluoresceinated anti-*M. hyorhinis* antiserum diluted in PBS, and mounted in 1:1 PBS:glycerol. The preparations were then scored for cells exhibiting specific fluorescence. At least 1,000 cells were scored for each determination. Cells treated with 5×10^{-3} M sodium azide (NaN_3) were exposed to this inhibitor during the entire process of washing, staining and mounting. In addition, these azide-treated cells were processed at 0 °C. Untreated cells were processed identically except that NaN_3 was omitted from the reagents and the manipulations were carried out at room temperature.

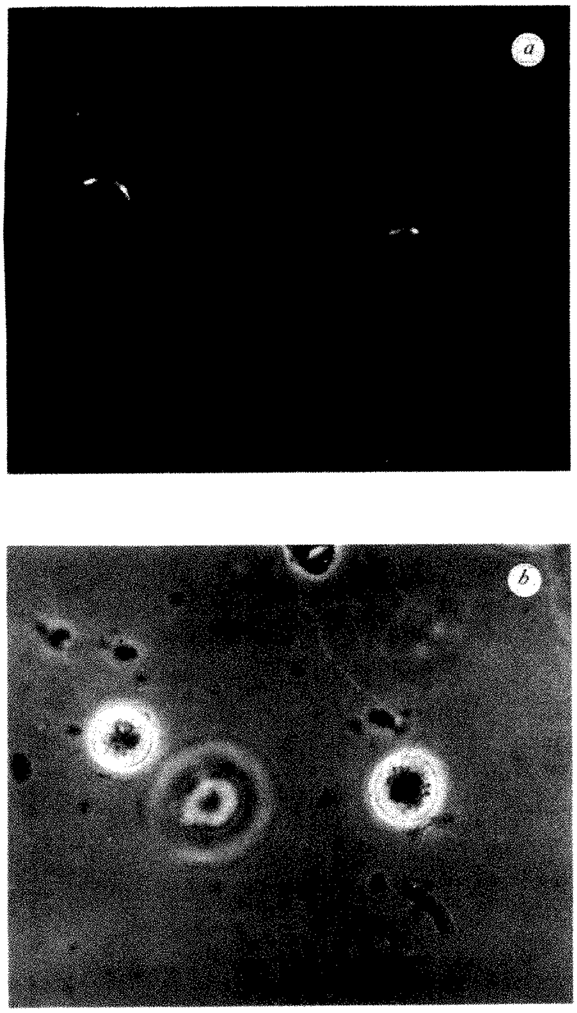

Fig. 1 S49 lymphoblastoid cells infected with *M. hyorhinis*. *a*, Capped mycoplasmas revealed with fluoresceinated anti-mycoplasma antiserum 24 h after infection. Magnification, ×1,200. *b*, Phase microscopy of the same field. Magnification, ×1,200.

Cells were then infected with $1-5\times10^7$ colony-forming units of *M. hyorhinis* and incubated at 37 °C. Cultures were taken daily for 3 d and blast formation was scored using phase optics according to the number of blast cells in a given lymphocyte population.

The number of dead cells was estimated by staining the unfixed populations with 0.5 μg ml^{-1} 4′-6-diamidine-2-phenylindole (DAPI), which enters dead cells and binds specifically to DNA. Thus, the nuclei of dead cells fluoresced when examined microscopically using the Leitz Ploem system whereas those of live cells did not. The degree of blast transformation was confirmed by fixing cells with 0.5% glutaraldehyde on ice for 10 min followed by staining with Jenner–Giemsa stain. Cap formation was monitored by immunofluorescent staining as described above. For comparison, parallel cultures of splenic lymphocytes were treated with 10 μg ml^{-1} of bacterial lipopolysaccharide (LPS), a potent mitogen for B lymphocytes[12].

We did not attempt to measure lymphocyte stimulation by the conventional thymidine incorporation assay[16] because our preliminary experiments (unpublished) gave highly variable results due to the nucleoside phosphorylase activity of mycoplasmas which catalyses the rapid conversion of thymidine to thymine[17,18].

Mycoplasma capping on S49 cells

The rate of formation of mycoplasma caps on the S49 lymphoblastoid cells is shown in Table 1. Initially, fluorescence was seen in very few cells and was predominantly distributed in an irregular patched pattern over the cell surface. Several hours after infection, the frequency of caps increased (Fig. 1), reaching a peak approximately 24 h after infection. There was no significant difference in the frequency of mycoplasma caps in the presence or absence of 5×10^{-3} M sodium azide, which is an inhibitor of respiration and consequently of energy-dependent capping[11]. This indicates that the mycoplasmas were behaving as multivalent ligands independent of specific anti-mycoplasma antibody. The kinetics of appearance of the caps after being distributed over the entire cell surface, as evidenced by early ring and patch fluorescence followed by capping, indicated a process of interaction and movement similar to that seen with ligands such as concanavalin A (refs 13, 14), albeit slower in rate.

Capping in the absence of specific antibody was clearly established in our ultrastructural studies. As Fig. 2 shows, mycoplasmas were commonly situated at one pole of a cell when examined by transmission electron microscopy. Scanning electron microscopy (Fig. 3) showed the polar accumulation of capped mycoplasmas particularly distinctly. Accumulation was often sufficient to deform the lymphocytes physically, and was also seen in the phase and immunofluorescent preparations shown in Fig. 1. Uropods formed at the sites of mycoplasma accumulation (Fig. 4), and the mycoplasmas clustered around the uropod were often associated with small membranous vesicles, presumably derived from the host cell surface membrane. Towards the latter stages of the 24-h infection period the mycoplasmas were shed from the surface of the lymphocytes as large aggregates containing the membranous vesicles of

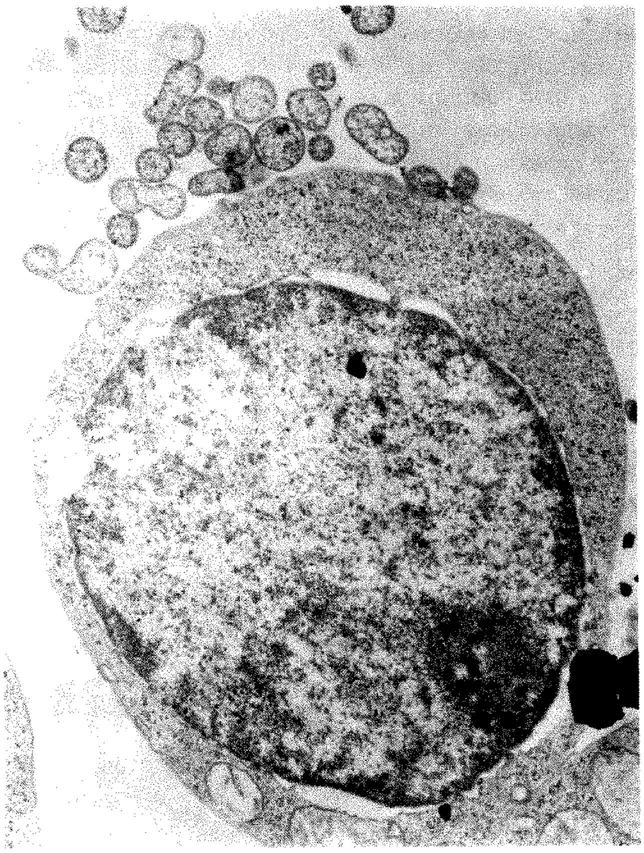

Fig. 2 S49 lymphoblastoid cell infected with *M. hyorhinis*. A cap of mycoplasmas is located at one pole of the cell. Cells were chilled on ice, washed once in 0.2 M Na cacodylate buffer, *p*H 7.2, fixed in the same buffer continuing 3% glutaraldehyde for 1 h, pelleted and fixed directly in 1% osmium tetroxide in Veronal buffer (*p*H 7.2; 0.5 mM $CaCl_2$). The pellet was then dehydrated in ethanol. Fixed cells in 100% ethanol were then warmed to room temperature, infiltrated with resin and further processed as described in the text. Magnification, ×18,000.

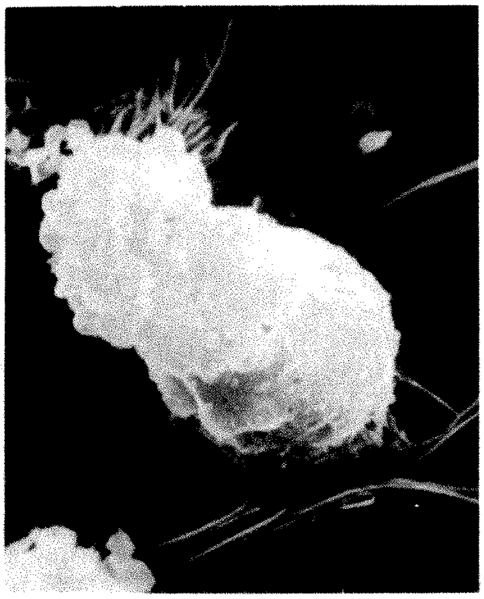

Fig. 3 Scanning electron micrography of an S49 lymphoid cell with a prominent cap of mycoplasmas. Fixation was accomplished by diluting with 0.2 M potassium phosphate buffer containing 2.5% glutaraldehyde, pH 7.5, 1 : 1 with medium, at room temperature. Cells maintained their original shapes at this dilution. The cells were washed with 0.1 M potassium phosphate buffer, pH 7.4, and allowed to attach to the surface of coverslips on which a thin layer of 1% poly-L-lysine (MW 70,000) had been dried[34]. Dehydration in ethanol was followed by transfer to acetone and critical point drying. Magnification, ×7,900.

presumed host origin. We saw no evidence of endocytosis, which is often seen when surface antigens are capped by antibodies[14,15]. In immunofluorescent preparations, shed caps appeared as distinct, freely floating, highly fluorescent aggregates.

Blast transformation of mouse spleen cells

M. hyorhinis behaved as a potent mitogen for both BALB/c and *nu/nu* splenic lymphocytes. Table 2 shows that the mycoplasmas were more effective than LPS in stimulating blast transformation. Although blast cells were not scored as such until obvious morphological changes had taken place, we noted subjectively that 'preblasting' (that is, the appearance of medium lymphocytes) occurred earlier and involved more cells in the mycoplasma-infected cultures than in the LPS-treated cultures, particularly those derived from *nu/nu* spleens.

Examination of infected cells by immunofluorescence revealed a series of events (Table 3) similar to that observed in S49 cells. Within 24 h of infection, approximately 40% of cells showed evidence of infection as measured by specific fluorescence. Most of these cells had distinct fluorescing caps and the remainder exhibited patchy fluorescence. Relatively few blast cells were visible but virtually all were capped. A significant number of blast cells had small pinpoints of specific fluorescence at a single pole of each respective cell, especially in the *nu/nu* cultures. By the second day of infection the number of blast cells with polar pinpoints of infection had increased considerably. In *nu/nu* spleen cultures in particular, many blast cells were seen which had no membrane-associated fluorescence; by day 3 most *nu/nu* blast cells failed to exhibit specific fluorescence.

We consider these series of observations to indicate that the process of infection, patching and capping is closely related to the induction of blast transformation in these cells. Furthermore, the caps seemed to be shed from the surface of the blasts, and reinfection of the stripped cells did not recur during the time of observation. Very few of the unstimulated or dead cells on days 2 or 3 were infected, as measured by specific immunofluorescence.

Significance of mycoplasma capping

The phenomenon of capping, first described by Taylor *et al.*[11], convincingly demonstrated that cell surface receptors which are normally distributed randomly in the plane of the membrane may be redistributed into patches and caps after crosslinking by multivalent ligands. This original study and subsequent reports[14,15,19] demonstrated capping by crosslinking surface antigens with antibodies directed against the surface antigens or by using soluble ligands such as concanavalin A (refs 13, 20). We believe that the studies described here are the first report of an infectious organism behaving in a fashion similar to soluble multivalent ligands and of capping on the surface of lymphocytes in the absence of specific antibody. Certain viruses are distributed in patches on the surface of lymphocytes in the absence of antibody, but the addition of specific antibody is required to induce capping[21].

The association between capping and blast transformation is also particularly striking. We do not yet know if mycoplasma capping is causally related to lymphocyte stimulation, but if this proves to be the case it may portend a physiological significance for capping during microbial infection. Several mycoplasma species have been shown to induce blast transformation of splenic lymphocytes *in vitro*[22-25] and result in polyclonal B-cell activation[26]. It will be interesting to see if there is a general

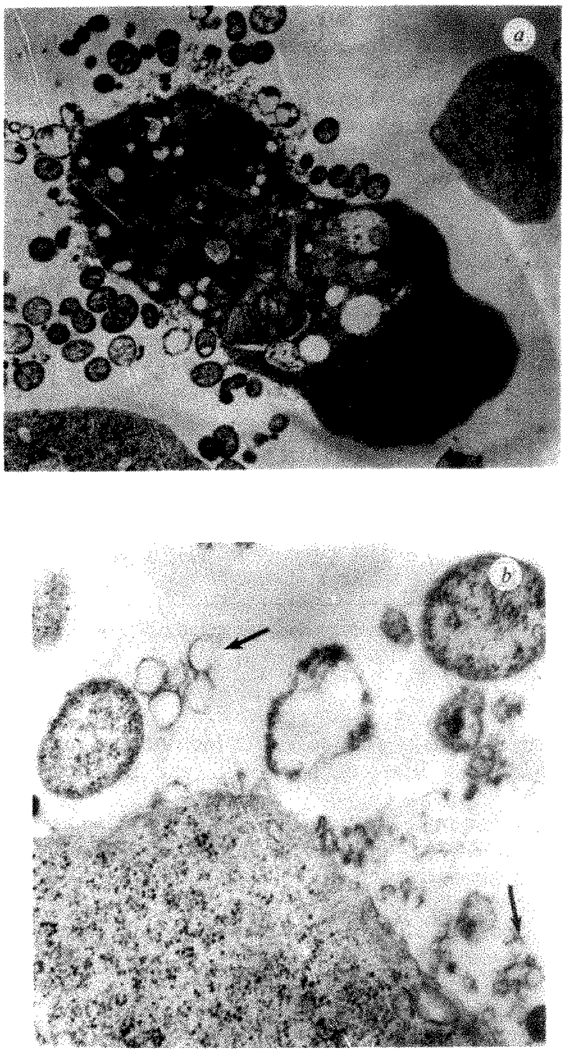

Fig. 4 Mycoplasma caps on S49 lymphoblastoid cells. *a*, Thin section of lymphocyte containing a broad cap of mycoplasmas associated with a uropod. Magnification, ×8,900. *b*, Higher magnification of a uropod showing membrane vesicles (arrowed) released from the cell surface. Magnification, ×40,000.

Table 2 Comparative mitogenic effects of bacterial lipopolysaccharide and mycoplasmas on mouse lymphocytes

Time post-treatment or infection (d)	Treatment of cells	BALB/c splenic lymphocytes: Total cells counted	% Blast cells	% Dead cells	*nu/nu* splenic lymphocytes: Total cells counted	% Blast cells	% Dead cells
	Control	483	0.6	24.6	503	1.3	24.4
1	LPS	509	1.9	25.5	503	8.1	22.0

The blastogenic transformation of the splenic lymphocytes was scored using phase optics and confirmed following fixation and staining with Jenner–Giemsa. Dead cells were determined by DAPI staining as described in the text. Blast cell percentages were calculated as per cent of total cells.

correlation between mycoplasma capping and lymphocyte activation with these other species. The strong correlation between mycoplasma caps and blast transformation suggests that this may well be the case.

Our preliminary results presented here also indicate that mycoplasmas seem to be a more potent mitogen than LPS. The isolation of the active mycoplasma components will clarify this possibility. The fact that both BALB/c and athymic nude splenic lymphocytes were stimulated suggests that the predominant cells affected are B lymphocytes. We have confirmed this using anti-immunoglobulin sera but have also found that a proportion of the stimulated cells do not bear immunoglobulin (Ig) on their surface (unpublished observations). We do not yet know if these represent a population other than B cells or whether surface Ig has been co-capped with the mycoplasmas. Our preliminary results with partially purified T cells indicate that they too are stimulated to a lesser degree (E.J.S. and B. Pires, in preparation).

Table 3 Relationship between mycoplasma capping and blast transformation

The distribution of mycoplasmas on infected cells was determined by specific immunofluorescence. Percentages in parentheses refer to pinpoint polar capping as discussed in the text.

Certain features of the mycoplasma–lymphocyte interactions described above may be important for our understanding of the pathogenicity of these microorganisms. Mycoplasma infections are usually self limiting but are occasionally followed by complications which are autoimmune in nature[2]. For example, *M. pneumoniae* causes primary atypical pneumonia in humans, a condition which is usually limited to the respiratory tract. However, documented sequelae to this infection include anaemia and neurological complications[2,27,28]. Also, antibodies directed against host tissue, including the I antigen of erythrocytes, lung and brain, have been found in the sera of patients infected with *M. pneumoniae*[28,30]. If mycoplasmas are capable of inducing B-cell activation *in vivo*, as they are *in vitro*, it is possible that 'forbidden' clones may be activated to produce autoantibodies.

An alternative way in which mycoplasma–host cell interactions may lead to autoimmune reactivity is by antigenic modulation. It is well established that during infection certain viruses alter the composition of the host cell's plasma membrane[31,32]. The changes which ensue include particularly the depletion or loss of histocompatibility antigens from the surface[32]. Antigenic modulation of cells following viral infection has been linked to the immunopathology caused by these infections. We have preliminary evidence that infection of mouse lymphocytes with mycoplasmas leads to the depletion of host cell surface antigens, including H-2 (unpublished observations). Similar losses of host antigens following mycoplasma infection of lymphocytes have been noted by other investigators[32]. It is possible that these surface antigens may serve as mycoplasma receptors and are stripped from the cell during the capping process and subsequent release of the cap from the surface of the lymphocyte.

In conclusion, we have shown that a novel feature of the infection of mouse lymphocytes with mycoplasmas is the capping of these organisms at one pole of the cell. Mycoplasma capping is correlated with a high efficiency of blast transformation; thus, mycoplasmas behave as potent mitogens. The caps are shed as aggregates from the surface of the lymphocytes and contain membranous vesicles which are presumably of host origin and may contain mycoplasma receptors. If this interaction has a parallel *in vivo* it may explain some of the autoimmune sequelae to mycoplasma infection.

We feel it is also appropriate to include a final note of warning that investigators using lymphocytes as model systems to investigate mitogenicity, lymphocyte triggering, surface antigens and viral pathology should, together with all other investigators using cultured cells, beware of mycoplasma contamination[1,7].

We thank Brian Pires and Joyce Wilkinson for technical assistance and Ms Cheryl Whitlock and Dr James Watson for discussions. This work was supported, in part, by a grant from the NCI. E.J.S. was a Leukemia Society of America Special Fellow during part of this work and is the recipient of a Research Career Development Award from the NCI.

HEAO Observations of X-ray bursts from MXB1730−335

BURST activity was observed[1] on 18 March 1978, from MXB1730−335, the rapid burster, from which no activity had been observed a few days earlier[2]. HEAO 1 was pointed (+y axis) at the rapid burster from ~18.00–21.00 UT on 31 March 1978. The source was actively bursting in the 'Mode I' pattern[3], in which very large type II bursts[4] are first followed by a long (several minutes) quiescent period and then by a train of closely spaced, small bursts. Because type I and type II bursts probably have different underlying physical mechanisms[4], it is important to study both types over a large energy range. We report here on a search for hard X-ray emission from the rapid burster and on evidence for spectral evolution in the type II bursts.

Fifty-eight minutes of quick-look data were examined from the A2 experiment and from the A4 experiment on HEAO 1. Two very large bursts were observed in both the A2 and A4 data (Fig. 1). Each lasted ~25 s and had a total energy flux (2–60 keV) of $3\text{–}4\times10^{-7}$ erg cm^{-2}. Five moderately sized bursts (~10 s duration, ~10^{7} erg cm^{-2}) and 167 small bursts (~5 s duration, $2\text{–}5\times10^{-8}$ erg cm^{-2}) were also observed in the A2 data. The two large bursts which occurred at 19 h 12 min 00 s UT and 19 h 48 min 54 s UT, are shown in Fig. 1, as observed in four energy channels from 13–160 keV by the A4 low energy detectors[5] (sum of count rates in two independent detectors each with an area of ~100 cm^2) and in a single, broad energy band, by the A2 detectors. The A2 data shown here are the sum of various energy channels in three separate detectors[6], spanning the energy range 2–60 keV. The A4 data were binned on-board the spacecraft into 0.64 s time bins and ~5 keV energy bins. Background counting rates were determined from ~200 s of data immediately following the 19 h 12 min 00 s burst and from ~35 s of data following a moderate-size burst ~13 min later (not shown in Fig. 1). They include the diffuse X-ray and charged particle background and any steady emission that might come from the rapid burster or from 4U1728−33 which are separated by only ~0.5°.

Because of the steep spectrum of the type II bursts from the rapid burster[3], more than 95% of the total A2 counts is due to photons with energies <13 keV. These data can therefore be considered effectively as an energy channel (2–~13 keV) preceding the first A4 channel (13–25 keV). The large type II bursts from MXB1730−335 in the A2 data seem to be similar to those observed in 1976 (refs 7–9), showing a broad maximum and a double-peaked structure during the burst decay.

Each burst was analysed in two nearly equal time segments. The ratio of counts in the last to the first part of the 19 h 12 min 00 s burst was 0.353±0.004 in the A2 data and <0.15 (3 σ confidence level) in the 13–25 keV channel of the A4 data. No significant detection of X rays was made at all in the A4 data after the first 13 s of the burst, while in the A2 data, at lower energies, the burst lasted ~25 s. The ratio of counts in the

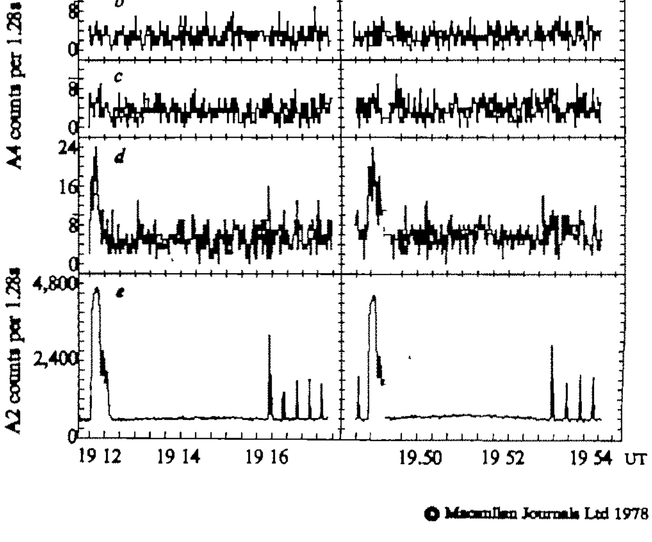

Fig. 1 HEAO 1 data for the rapid burster (MXB1730−335) on 31 March 1978. The enhancement after the large bursts is probably 'steady' X-ray emission as previously observed from the rapid burster[4,19]. *a*, 85–160 keV; *b*, 40–85 keV; *c*, 25–40 keV; *d*, 13–25 keV; *e*, 2–60 keV (95% of counts <13 keV).

0028-0836/78/0276—0587$01.00

last to the first half of the 19 h 48 min 54 s burst was 0.467 ± 0.006 in the A2 data and 0.30 ± 0.08 in the A4 13–25 keV channel. In both bursts, the X rays with energies above 13keV decayed faster than the lower energy X rays; that is, the spectra softened during the burst decay. The spectral evolution of the bursts can perhaps also be seen from the A2 data alone. In both xenon detectors in which the bursts were observed, the ratios (comparison of second and first half of the bursts) for counts above 9 keV were less than the ratios for counts below 7 keV, with a significance slightly greater than 3 s.d.

We conclude that the type II bursts from the rapid burster do show a spectral softening during burst decay. However, this spectral softening is not nearly as pronounced as in type I bursts, either from MXB1730 − 335 (ref. 4) or from other burst sources[10–13]. Marshall *et al.*[3] found that the spectra of type II bursts from MXB1730–335 as measured by SAS 3 do not change significantly during burst decay. However, the SAS 3 data were not sensitive to the spectral evolution reported here. The highest energy channel with a statistically significant signal in the SAS 3 data was 8–19 keV. For the spectrum of these bursts, this energy channel is dominated by X rays below 10 keV, and the spectral softening reported here could not have been detected.

We searched for the existence of a flux in the 86–160 keV energy range. Combining all the data (corrected for collimator transmission), we find a 90% confidence upper limit[14] of $<1.7\times10^{-8}$ erg cm^{-2} per burst in the range 85–160 keV corresponding to $<2.0\times10^{38}$ erg per burst at a source distance of 10 kpc. The average energy of these two bursts as detected by A2 in the 2–20 keV energy range was $(4.4\pm0.5)\times10^{39}$ erg per burst at 10 kpc. This value is similar to that measured previously for large bursts from the rapid burster[7,8]. Thus large type II bursts from the rapid burster contain <5% of their total X-ray energy in the range 85–160 keV.

This lack of a hard X-ray flux has consequences for those accretion instability models of X-ray bursts which require extremely high temperatures; for example, super-massive black holes ($\sim10^5 M_\odot$) surrounded by a $\sim10^9$ K hot cloud[15] or spherical accretion of compact H II regions on less massive black holes ($\sim$10–100 $M_\odot$)[16]. In the latter, the low energy (<20 keV) burst should be accompanied by at least as luminous a burst in hard X rays (≳100–200 keV). Our present observations, of the absence of any apppreciable flux in the range 85–160 keV, do not, of course, rule out the possibility that a large amount of burst energy is present above 160 keV.

Other evidence has accumulated that sources of type I bursts are not massive black holes but objects of solar mass[9,13,17,18]. As the rapid burster itself is also a source of type I bursts[4], these results for the type II bursts (which are almost certainly due to accretion instabilities) then limit the production of hard X rays that are allowed in the accretion on a neutron star or a small black hole.

NGC326—a radio galaxy with a precessing beam?

THE radio emission from most strong extragalactic sources is concentrated in a band which passes through, and is symmetrical with respect to, the associated galaxy[1]. This structure is sometimes modified to a V or C shape with the galaxy at the apex, as in the wide angle tail sources like 3C465 (ref. 2), and occasionally to the more extreme elongation of the tail sources such as NGC1265 (ref. 3). In a few sources an S-shaped or 180° symmetry is seen. This was first noted in the outer components of Cen A[4] and a better example is 3C272.1 (refs 5, 6). Other sources where the S distortion is very clear have been found with higher resolution observations (for example Cyg A[7] and 3C47[8]). In these, the structure in question subtends a small angle from the centre and they give a strong impression of a beam type of model in which the beam has wobbled or precessed by a few degrees[9]. A new example of a radio source showing a structure with a 180° symmetry, but not of the S form, has been found as part of a systematic study of radio galaxies of lower luminosity selected from the B2 catalogue[10]. The projection of a precessing beam model seems to provide a natural explanation for this strange shape and is described here.

The radio source B20055+26 (4C26.03) was first mapped with the Westerbork Synthesis Radio Telescope in a program at 1.4 GHz in which short observations were obtained of all the B2 radio sources identified with bright galaxies[11]. Because an interesting structure was seen this was followed up by a 2 × 12 h observation at 5 GHz resulting in a map with resolution 6″ × 13″ (RA × dec) and r.m.s. noise of 0.8 mJy (1 mJy = 10^{-29} W m^{-2} Hz^{-1}) beam area. This map is shown in Fig. 1 and the position of the elliptical galaxy NGC326 is indicated. This galaxy is the brightest member of a small group of galaxies, Zwicky 0056.9+2636, and has a redshift of 0.0472 (ref. 10). There is a fainter elliptical galaxy 2′ NE and the other members of the group are more than 5′ away.

The radio map shows two curving tails with a 180° symmetry. There is also emission at the position of the galaxy. This may be a

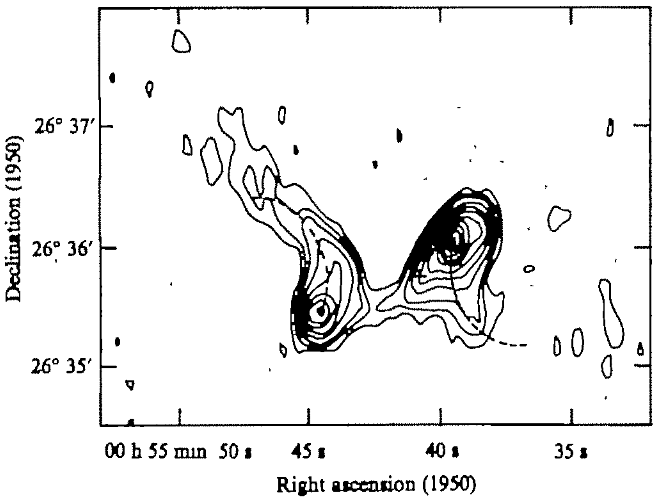

Fig. 1 5.0 GHz map of the brightness distribution of B2 0055+26. Contours are 2, 4, 6, 8, 10, 15, 20, mJy per beam area. The r.m.s. noise level is 0.8 mJy per beam area. 1 mJy per beam area = 0.53 K. The position of the galaxy NGC326 is indicated by the +. The dashed lines shown the trajectories of the ends of the beams for the model discussed in the text.

separate compact source (such as is often seen in radio galaxies at this frequency) which is blended together with the emission from the western component or it may be part of a bridge connecting the galaxy and the heads of the two components. The 180° symmetry is even more striking if the emission at the position of the galaxy is a separate compact source because then the ridge of extended emission will curve south from the west component in the identical way that the tail curves to the north-east from the eastern component making the symmetry almost perfect about a position RA = 00 h 55 min 42 s, dec = +26°35′44″, 0.5′ east of the galaxy.

Comparison of the 5 GHz map with the 1.4 GHz data indicates a spectral index of −0.7 in the bright inner regions and this steepens to a value of ≲−1.1 in the tail going to the north-east and in the very low brightness region just visible above the noise in the south-west corner of Fig. 1. Other data for this radio galaxy are summarised in the Table 1.

Either component taken separately has a structure remarkably similar to that seen in the tail radio sources but the morphology of the two components together and the location of the galaxy make it impossible to ascribe their shape to a trajectory of the galaxy in this case.

Complex radio source morphologies are now often attributed to the interaction with the intracluster medium, for example, Lari and Perola[12] have shown that in a given luminosity range the number of complex sources found inside rich clusters of galaxies is considerably higher than the number found outside.

Table 1 Observational Data for NGC326—B2 0055+26

Radio power (1.4 GHz)		3×10^{23} W Hz^{-1} ster^{-1}

* $H = 100$ km s^{-1} Mpc^{-1}.

This radio source is not located in a rich cluster and, furthermore, its distortion has a symmetry which cannot readily be explained as an effect of the surrounding medium. Thus we are lead to conclude that in this case the shape is determined by the source energising the radiating plasma rather than by the surrounding medium. The observation of the change in spectral index implies that the regions of high brightness are the youngest so we might consider models in which the energy is supplied by a beam which has rotated through about 90° while generating the source and now points to the region of high brightness. At first sight this kind of model seems somewhat implausible as the region just behind the head is closer to the galaxy so requiring a variation in the power of the beam which is not reflected in the monotonic change of brightness. However, when we consider the effect of projection on the trajectories of the ends of a pair of beams sweeping out two cones on either side of the galaxy (Fig. 2) we can find an impressive agreement with the observations. The dotted lines in Fig. 1 show the trajectories of the ends of the beams in a model in which the beam is offset from the axis of rotation by 18° and wth the axis of rotation inclined to the line of sight by 30°. In such a model the observed change in brightness from the head to the end of the tail is a natural consequence of the increasing age.

Models in which the radiating plasma is energised by a beam emanating from the nucleus of the galaxy have been proposed by Rees[13], Longair *et al.*[14] and Blandford and Rees[15]. Furthermore, Miley[9] and Hendrikson and Bridle (unpublished) have suggested that the S symmetry seen in some sources could be due to the changing orientation of such a beam. For NGC326 the high degree of symmetry and excellent fit to the model indicates a fairly uniform rotation of a beam offset from the rotation axis by a relatively large angle and generating the radiating region at a constant distance from the galaxy. The continual motion of the beam through the intergalactic medium and the maintenance of a constant distance from the galaxy to the radiating region will present some interesting problems and constraints on the types of beam models proposed[13–15].

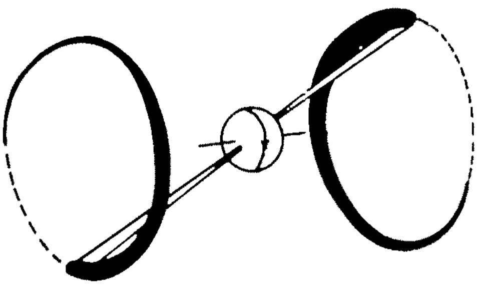

Fig. 2 A sketch showing the essential features of the proposed model.

The rotating offset beam may be caused by a real offset between the beam and the rotation axis of the material supporting it, or the beam may be aligned with the rotation axis of a gaseous disk in the galaxy which is precessing because of a difference between its rotation axis and the principal axis of the galaxy as a whole. The observation of a difference between the rotation axis of the HI and the optical minor axis of the elliptical galaxies NGC4278 (ref. 16) and NGC1052 (ref. 17) provides support for the latter speculation.

We can make a rough estimate of the time scales involved from the observed steepening of the radio spectrum. If this steepening is due to energy losses the age of the ends of the tails would be ≲4×10^{7} yr, however, in tailed radio sources we know that the ages estimated from the kinematics are considerably longer than those determined from the spectral steepening[18,19]. If we compare the steepening of the spectrum seen in this source with that seen in tail sources then the age of the end of the tail is more likely to be ≈2×10^{8} yr corresponding to a period of

~6×10^8 yr for the full circle. In the inner part of elliptical galaxies where solid body rotation is seen the rotation periods are about 10^7 yr (ref. 20), which may be too short to explain the radio data on the basis of the offset beam. If the motion of the beam is caused by precession of a gaseous disk the longer time scale implied by the radio data becomes reasonable.

If the radio axis is associated with a much smaller object such as a black hole in a tilted accretion disk then the motion of the axis will be related to the Bardeen and Petterson effect[21] as discussed by Rees[22].

We thank Drs R. Sanders and M. Rees for helpful discussions. The Westerbork Observatory is operated by the Netherlands Foundation for Radio Astronomy with the financial support of the Netherlands Organization for Pure Research (Z.W.O.).

Limits on cosmic radio bursts with microsecond time scales

IT has been suggested[1] that black holes of mass $\leq10^{15}$ g evaporate in ~10^{10} yr, ultimately annihilating into a burst of energetic photons and particles. This explosion would produce γ-rays directly, and a radio pulse with a characteristic frequency of ~3 GHz and an energy of ~10^{32} erg may also be generated[1]. It has been shown[2–4] that such a radio burst would be far more easily detected than the corresponding γ-ray burst. Estimates of the energy in the radio burst are uncertain by many orders of magnitude, and it is, of course, not known whether any primordial black holes exist at all; however, the implications of a detection would be enormous for quantum and gravitational physics.

The observational requirements to make an optimal search for a pulse with a ~3 GHz frequency are in themselves interesting as the predicted pulse is only one radio frequency cycle in duration and by definition this event will never be repeated. Such a short pulse will contain all radio frequencies up to a cut-off determined by the actual duration of the pulse so an optimum receiver would have very wide bandwidth, B, and a time constant limited only by the reciprocal of this bandwidth. Unfortunately any pulse originating outside the local region of the galaxy will be dispersed by the interstellar medium thereby reducing the maximum possible sensitivity. For example, in a 10 MHz band at 5 GHz we would expect dispersion to smear pulses to ≥10 μs. It is interesting to note that pulses of this character would not be detected with the time constants commonly used in radio astronomy (even for pulsar surveys) although such a pulse can easily be detected with a suitably designed receiver. The existence of this unexplored time domain for astrophysical phenomena provides additional incentive for such a search.

Limits on the radio pulse emission rate from exploding black holes have already been set by using negative results from wide-beam searches for radio pulses such as might be produced by supernovae[3,4]. In contrast to the small, low-gain antennas used in those searches, we have used the 25-m Dwingeloo radiotelescope; our objective was not only to probe large volumes of space for possible bursts from exploding black holes, but also to observe a variety of specific objects with high sensitivity and time resolution.

Table 1 Sources observed

	Source	Time on-source (h)	Limiting energy (erg)
Planet	Jupiter	2	6×10^6
Star	Algol	3	1×10^{25}
Pulsars	PSR0950+08	3	3×10^{26}
	PSR1133+16	3	3×10^{27}
Supernova remnant	Crab	1	2×10^{30}
X-ray sources	Sco X1	2	3×10^{29}
	Her X1	1	5×10^{30}
	Cyg X1	6	5×10^{30}
	Cyg X2	6	7×10^{28}
Globular clusters	M3	4	3×10^{31}
	M92	6	2×10^{31}
	M15	2	5×10^{31}
Normal galaxy	M31	3	5×10^{35}
Radio galaxy	M87	2	2×10^{37}
Quasar	3C273	3	1×10^{41}

We used a 5 GHz cooled parametric receiver providing a total system temperature of 65 K and an instantaneous bandwidth of 100 MHz. The beamwidth was 10′ arc and the sensitivity was ~0.1 K Jy^{-1}. The detection instrumentation was based on a single channel high speed receiver, which could be optimised for the range of dispersion measures expected. The backend consisted of an input filter of 10 MHz bandwidth with a characteristic double hump shape to facilitate dispersed pulse identification. A detector with a 2 μs time constant followed. Pulses were detected by a comparator which compared an adjustable fraction of the instantaneous power with the average power. Pulses were thus detected when the observed temperature exceeded the average system temperature by a preset factor.

These events were recorded in two ways. Initially, a simple pulse duration discriminator was used to discriminate against pulses which were shorter than expected from dispersion, and the remaining events were indicated on a chart recorder. Later in the observing period it became possible to photograph such detected pulses with the aid of a storage oscilloscope and camera, thereby improving our interference and noise rejection capability.

We observed various objects (Table 1) alternating between a 1 h observation on-source and a 1 h observation at an off-source position 1 h later in RA. The event rate was generally near zero, but occasionally rose to ~10 h^{-1} changing on a timescale unrelated to our observing schedule. Inspection of the events recorded on film showed that the faster event rate was caused by pulses with a regular modulation presumably due to terrestrial interference. Almost every other pulse observed could be attributed either to internally generated spikes (characteristic and repeatable shape, associated with the switching of telescope

0028–0836/78/0276—0590$01.00

drive motors) or simply to noise (too short for the expected dispersion and consistent with statistical expectations). For the two sources (Jupiter and Algol) for which no dispersion would be anticipated no events of any timescale were recorded. Only one event looked anything like a real dispersed cosmic signal, and that was on a reference for Cyg X-1.

With the discriminator set at about three times the system temperature, the limiting sensitivity is

$$E_{\text{lim}} = 10^{32}\tau\left(\frac{\nu_c}{5}\right)\left(\frac{D}{100}\right)^2 \text{erg} \tag{1}$$

with the pulse duration τ in μs, upper cut-off frequency ν_c in GHz, and distance D in kpc. Dispersion in the interstellar medium determines τ, and for our observing frequency and bandwidth $\tau(\mu s) \approx DM$ (pc cm^{-3}). The dispersion measure (DM) was estimated using a model of the electron distribution in the galaxy[4,5], and substituted in equation (1) to give

$$E_{\text{lim}} \sim 10^{32}\left(\frac{\nu_c}{5}\right)\left(\frac{D}{100}\right)^2 \times\left[\frac{19}{\sin b}(1-\exp(-1.7D\sin b))+10^{-4}D\right] \text{erg} \tag{2}$$

where b is the galactic latitude. The $10^{-4}D$ term allows for additional dispersion by an intergalactic medium with $n_e = 10^{-7}$ cm^{-3}, but this is only important for the most distant sources. Taking the characteristic frequency to equal the observing frequency (the most optimistic case), the limiting energies for the various sources are given in Table 1.

Observations of all sources listed in Table 1 can be used together with the reference observations to set an overall limit on the rate of 10^{32} erg radio bursts from exploding black holes. Taking the maximum distance sampled in each direction as that for which E_{lim} from equation (2) is 10^{32} erg, we find a limit of 9×10^{-6} pc^{-3} yr^{-1}. This compares with the limits derived in the earlier analyses[3,4] of radio data, and is far superior to limits obtained from searches for γ-ray bursts.

It may be more interesting to consider the globular clusters separately from the other sources. If the primordial black holes have a space distribution similar to that of the visible matter in the Universe, then there would be concentrations of them in globular clusters. Taking $10^5 M_{\odot}$ as a typical mass for a globular cluster, the limits in Table 1 imply an upper limit of 10^{-20} yr^{-1} for the fraction of the total mass which evaporates due to 10^{15} g black holes exploding and generating 10^{32} erg radio bursts. In other words, primordial black holes of $<10^{15}$ g can never have exceeded 10^{-10} of the total mass.

An even larger mass is sampled in the M31 observations where our beam corresponds to a linear size of 2.6 kpc. However, the additional dispersion in M31 and the greater distance result in a much higher detection limit.

These limits could be improved by using larger telescopes for longer times and simultaneous observations with more than one antenna. Interference rejection in particular would be greatly facilitated by using two or more widely spaced antennas. Large improvements could be achieved either by using a fast multichannel dedispersing backend or possibly by observing at higher frequencies.

We thank V. Radhakrishnan for discussions. The Dwingeloo radiotelescope is operated by the Netherlands foundation for Radioastronomy (S.R.Z.M.) with the financial support of the Netherlands Organization for the Advancement of Pure Research (Z.W.O.).

Photographic amplification of faint astronomical images

METHODS of contrast enhancement in astronomy, such as optical contrasting[1] or optical printing onto a high-contrast material, include all grains throughout the emulsion thickness, and noise (fog), as well as the image, is enhanced. Fairly high levels of chemical fog (up to diffuse densities of 0.3) are common when plates are optimally hypersensitised by baking or prolonged soaking in nitrogen followed by reduction sensitisation in hydrogen gas. Shaw[2] has shown that chemical fog seriously affects the detective quantum efficiency (DQE) of an emulsion when all the fog grains appear in the image as additional noise. I describe here a method that has been devised to make visible extremely faint images on astronomical plates without imaging fog grains. The images are not apparent on visual inspection and cannot be detected by conventional macro-densitometry. These effects result in a significant improvement in the visual detection of faint images on the original plate over the density range occupied by threshold imagery. The technique is most useful for revealing faint nebulosity and low surface brightness features on fine-grain high-contrast emulsions such as Kodak spectroscopic plates type IIIa.

The technique depends on the fact that faint images tend to be located in the uppermost layers of the developed emulsion whereas grains due to chemical fog are distributed at random throughout the total thickness of the emulsion coating. Unlike most film products, spectroscopic plates do not have a transparent protective super-coat to prevent abrasion. The faintest and sharpest images therefore occur at the emulsion–air interface. By using a diffuse-light vacuum-contact printer it is possible to make contact copies of original plates which record the upper layer image only. Fog grains at lower levels are not resolved and add a uniform neutral density which has no effect on the image. The signal-to-noise ratio is thus improved. With sky-limited plates the faint signal is only slightly denser than the uniform exposure from the sky background. The use of a high contrast copy film and careful control of exposure ensure that a very narrow range of densities around the signal level is expanded without the addition of background noise from deeper within the emulsion.

To produce the contact copies a commercially available diffuse-light vacuum-contact printer is used. A simple modification to enable a wide range of original plate densities to be handled has been previously described[3]. Agfa Gevaert graphic arts film type FO 71p has several characteristics which make it particularly suitable for use with this method. This high-contrast film has an orthochromatic fine-grain emulsion with developer components built into it for use in a stabilisation processing machine. The film can be processed in any alkaline solution but in practice a standard print developer at normal strength gives rapid and uniform results by processing in open trays. Development is effectively complete in less than 2 min at 20°C and consistent results are not significantly dependent on the degree of agitation in the developer solution. Conventional stop bath, fixation and washing complete the processing. Lithographic (infectious development) materials produce too much contrast for this method.

The contact exposure is adjusted so that the true sky background, well away from any nebulosity or vignetting, develops to a diffuse density of 0.4–0.6 on the copy positive. At this point on its characteristic curve the film has a very high gamma, so exposure is critical. The processed copy may be enlarged or contact printed onto a hard grade of paper to give a negative print. Again, exposure is critical and should be arranged so that substantial density is produced in the sky background.

The method is most successful with fine-grain high-contrast plates such as Kodak types IIIaJ and IIIaF. In coarser-grained emulsions faint images are scattered to greater depths within the recording layer[4] and the contrast in faster emulsions tends to be lower. Copies of plates are less suitable than originals as the relative positions of image and fog grains have been changed, particularly if a collimated or distant point light source was used to make the first copy.

Unlike most optical methods of copying, the technique can be used with plates of any size, limited by the contact printer and available film stock. The largest plates copied to date have been 355×355 mm plates from the UK 1.2-m Schmidt telescope. Dish processing of these large sheets of film is possible because the process is so simple. However, the originals must be of the best quality. Plates taken in very thin haze which appear perfectly acceptable show alarmingly large haloes around the brighter stars when copied as described. The extent of telescope vignetting and internal reflections are likewise clearly revealed as are development defects and marks due to handling and surface abrasions on the original plates.

IIIa plates exposed so that the sky background density reaches about 1.0 (ANSI diffuse) above fog seem to show the faintest objects. In these circumstances all the faint imagery is on the steep part of the characteristic curve where the output signal-to-noise of the emulsion is at a maximum[5]. Figure 1 is a high-contrast derivative of a sky-limited IIIaJ/GG 395 plate of Centaurus A (NGC5128) taken on the UK 1.2-m Schmidt telescope at Siding Spring, Australia. The visual appearance of the original plate is illustrated by the inset, which has the same scale and orientation. Both prints were obtained from the same plate. The NE–SW extension and western loop of Cen A described by Johnson[6] are almost burned out in this reproduction but much new filamentary material can be seen, particularly to the south and west. The reality of this faint material is confirmed on other high-contrast derivatives made from different original plates; it continues on to adjoining SRC Sky Survey fields. It could well be galactic in origin and not associated with Cen A. Even so, that nebulosity which is obviously associated with Cen A extends along the major axis over a distance of approximately 1.2°.

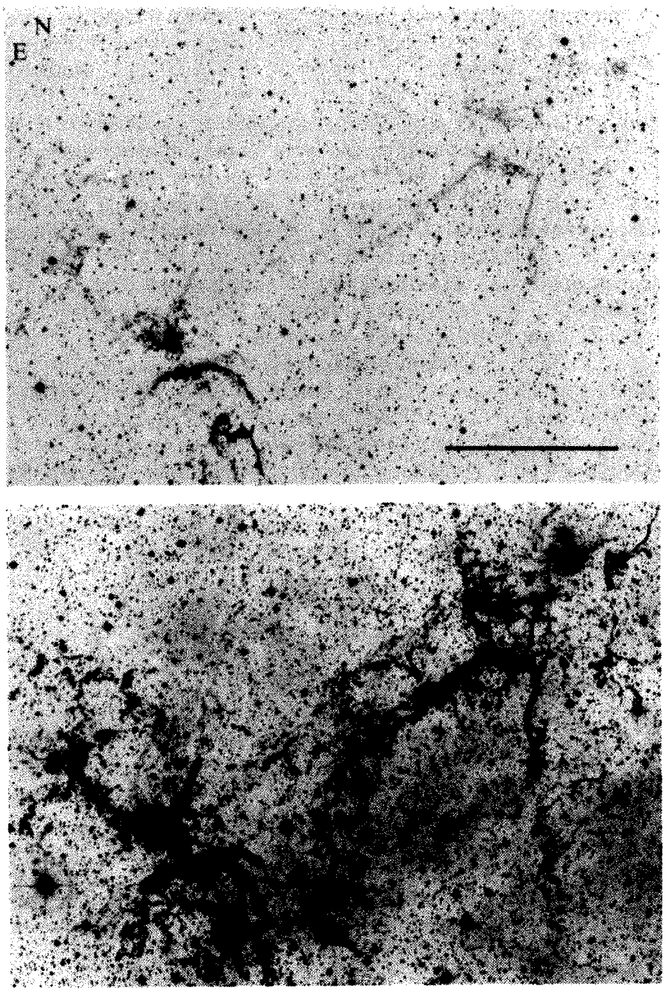

Fig. 1 Faint filaments around Cen A (centre). Inset shows visual appearance of original plate. Both prints have the same scale and orientation and are from the same IIIaJ plate taken on the 1.2-m UK Schmidt telescope. Scale bar, 30 arc min.

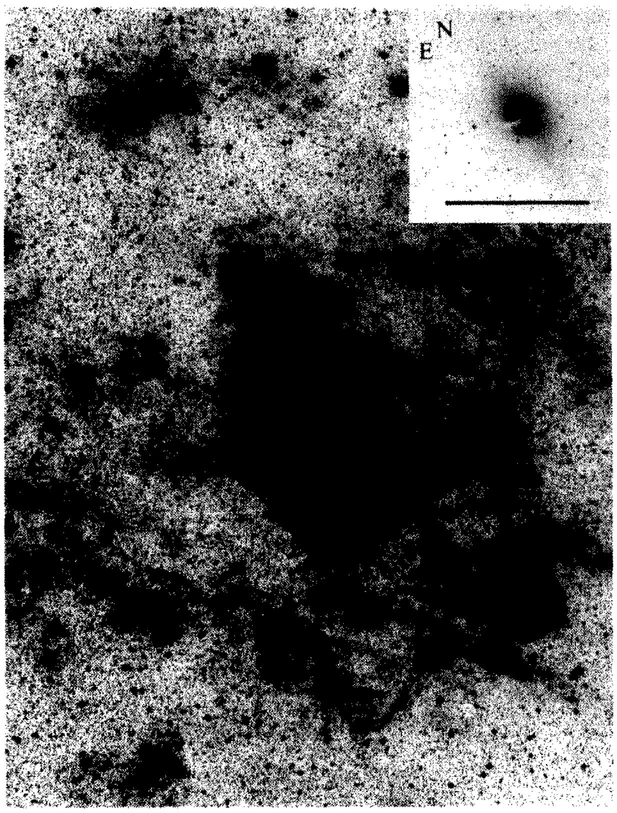

Fig. 2 Part of the Puppis supernova remnant from a deep IIIaF/RG630 plate taken on the 3.9-m Anglo-Australian telescope. A normal copy of the plate (above) is compared with a contrast-enhanced version of the same plate (below) printed with the same scale and orientation. Scale bar, 5 arc min.

The quantitative brightness of the faintest objects revealed by the technique is difficult to determine. However, the method seems capable of resolving structure about 0.5% brighter than the night sky (Cannon, personal communication), and Carter (unpublished results) has recently derived a B value, from deep IIIaJ plates of 22.9 mag arc s^{-2} for the night sky at Siding Spring. These values imply that the faintest features on the prints have a surface brightness of about 29 mag arc s^{-2}.

Figure 2 shows part of the Puppis supernova remnant, photographed on a IIIaF/RG630 plate using the 3.9-m Anglo-Australian telescope. Both illustrations have the same scale and orientation and are made from the same plate. The upper print represents the normal visual appearance of the plate but the lower print, made with the amplification technique, shows faint filaments and diffuse background nebulosity not previously observed.

This simple technique has been used with success on objective prism plates, direct and image tube spectra plates and non-limiting exposures on spectroscopic plates from several sources. It can be undertaken with commercially available equipment and materials and requires no special skill in its operation.

I thank Dr R. D. Cannon for permission to publish the deep photograph of Cen A and the staff of the UK Schmidt Telescope Unit for access to original plates.

Possible identification of the 45-μm ice signature in Orion

THE composition and size distribution of interstellar dust are controversial matters. Even the ice contribution to the well known and conspicuous 3-μm feature of the extinction curve has recently been questioned. We now report a study of the middle-infrared spectrum of dust emission. This spectral region is of interest because it includes the 45-μm band of water ice which, unlike the 3-μm feature, is characteristic of the ice lattice—being essentially due to stretching vibrations of the H–O bond. The 45-μm band also carries information on the physical state and temperature of the ice[1]. If the ice is amorphous, the band is wide (~19 μm) and, at 100 K, peaks at 45 μm; crystalline ice produces a narrow peak ~2 μm wide at 43.5 μm, for a temperature of 100 K; these characteristics are all temperature dependent. Note that the only possible crystalline phase at pressures below 1 bar is Ic (cubic) or Ih (hexagonal), for both of which the above statements are true. The relevant lattice vibrations are essentially translational and probably associated with the transverse optical branch of the dispersion diagram. Our results suggest an emission due to predominantly amorphous ice.

In the simplest astrophysical model, the 45-μm feature can be observed in emission from hot sources or in absorption through cold dust against a hot background. In the Northern Hemisphere, the bright Kleinmann-Low (KL) nebula is particularly suitable[2]. Observations were made using a grating spectrometer mounted at the Cassegrain focus of a 30-cm telescope on board the C.E.V. Caravelle, with a focal distance of 2,400 mm (ref. 3). Other system characteristics are given in Fig. 1 legend.

The airborne observations were carried out over France on 28 February and 13 March 1978, at a constant altitude of 11,300 m. The outside temperature was −53 °C and the dew point −55 °C. The pressure was ~210 mbar and the line-of-sight elevation remained between 27 and 33 °C. The telescope was pointed to the KL nebula, offsetting from θ^1C in the Trapezium, and the field of view was 4.5 and 1.8 arc min in elevation and azimuth respectively. The latter corresponds to a spectral slit width of 2.5 μm for an extended source and 1.3 μm for a point source, if alignment is perfect.

The overall spectral transmission (t_i) of the instrument, including the detector, was calibrated against a black body in the laboratory, before and after the flight. Atmospheric absorption bands were used to calibrate the wavelength scale. From the difference between spectral transmissions obtained at black-body temperatures of 200 and 400 °C, we conclude that the error on relative transmission values is <10%. The error on absolute values is not relevant to our purposes. Atmospheric transmission (t_{atm}) was computed on the basis of a standard Earth atmosphere[4] for different moisture contents (w) and spectral slit widths $(\delta\lambda)$. A satisfactory fit to the observed spectrum is obtained for 5.2 μm zenithal precipitable water and $\delta\lambda = 1.5$ μm. The average (I_{raw}) of eight of the recorded spectra, taken in identical conditions (except for the interchange of beams, which eliminates spurious offset signals) was considered as representative of the data, and divided by $t_{atm} \times t_i$ to give the spectrum (I_{KL}) of the nebula.

In addition to the usual noise sources, our study was affected by fluctuations in the effective wavelength of the detected radiation for a given setting of the grating; this was due to telescope pointing fluctuations. Using the apparently fluctuating locations of the H_2O absorption bands at 35.6, 40.2 and 44.3 μm, the standard deviation (σ) was ~0.4 μm (corresponding to a pointing deviation of 0.7 arc min). As a consequence, averaging over several spectra leads to an apparent widening of the slit, which was taken into account in computing t_{atm}.

Figure 1 represents the spectrum of the KL nebula, I_{KL}, together with that, I_b, of a body at 80 K having an emissivity proportional to λ^{-1}. The latter is very close to the spectrum of a grey body at 100 K and both fit reasonably well experimental data obtained at lower resolution over a wider band[2,3]. Our data are similar to those obtained by Ward[5] in the same range. Both studies indicate a bump at about 43 μm. If this is attributed to the amorphous ice feature, with a peak at $\lambda_0 = 43$ μm and a FWHM $\delta\lambda = 19$ μm, then, trying to fit a function of the form

$$I_b\left\{A + B\exp\left[-4\ln 2\left(\frac{\lambda - \lambda_0}{\delta\lambda}\right)^2\right]\right\}$$

through the data points gives $A \simeq 1$, $B \simeq 0.4$, corresponding to the dashed curve in Fig. 1. This set of values is obtained assuming a constant r.m.s. noise voltage over the spectral range and the validity of the fit is confirmed by the χ^2-test (reduced $\chi^2 \simeq 1$). The error bar at 43 μm in Fig. 1 represents the relative standard deviation of the fit $(\pm\sigma/A)$. (At 43 μm, this is equivalent to a r.m.s. noise voltage of 120 nV Hz$^{-1/2}$ on the detector, per spectral element). The choice of the exponential form for fitting was made for lack of a better knowledge of the ice 45 μm band profile in terms of dust extinction. It was intended to assess the objective existence of a feature near

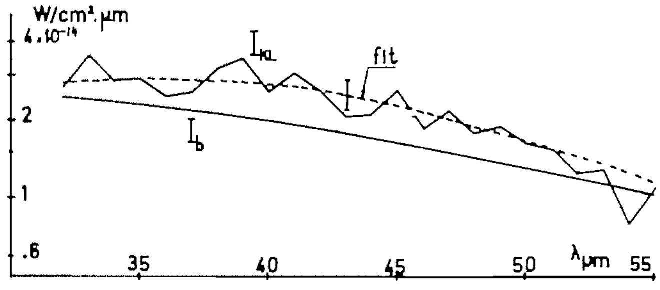

Fig. 1 I_{KL}, average measured spectrum of KL nebula, corrected for instrumental and atmospheric transmission. I_b, grey body spectrum, $T = 80$ K, $\varepsilon = \dfrac{30}{\lambda\,(\mu m)} \times 0.1$. Dashed curve, least squares fit to I_{KL}. Error bar $\pm\sigma/A$, where σ is the standard deviation of the fit (see text). Spectrometer system characteristics: aluminium echelette grating, ruled at 20 lines per mm, 20×20×6 mm in size blazed at 42 μm, in a folded Czerny–Turner design. The entrance hole is circular, 3.2 mm diameter. Average system transmission 3%; detector is a Low bolometer, with BaF_2 Reststrahlen filters. The grating is driven by a synchronous motor, through a gearbox at an average speed of 0.1 μm s^{-1} between 30 and 60 μm. The telescope secondary is wobbled at 20 Hz, with a sinusoïdal beam throw of 3 arc min.

0028-0836/78/0276—0593$01 00

45 μm, which it does indeed, since B/A (40%) is clearly larger than σ/A (17%), notwithstanding possible errors in instrumental spectral response (<10%).

The data therefore seem to indicate the presence of an emission due to predominantly amorphous ice. Its relative amplitude (B/A) is, however, much smaller than predicted for an optically thin cloud permeated with 'standard' core-mantle grains[6,7]. Since KL is indeed thin in the wavelength range considered ($\tau \sim 0.1$, from the comparison of colour and brightness temperature), the data would point to a shell model where the ice mantles are only present at the periphery of the nebula[6]. A satisfactory fit of such a model to the experimental data still requires proper tailoring of grain dimensions and densities, shell radii and central heating source.

We thank the members of the IR groups at Saclay, Meudon and Groningen, who helped to build and operate the instruments. Airborne operations were carried out, through the Institut National d'Astronomie et de Géophysique, by the Centre d'Essais en Vol. This work was supported by the Centre National d'Etudes Spatiales in France, and, in the Netherlands, by the Royal Academy of Science through the Committee for Geophysics and Space Research.

Atomic oxygen emission at 63 μm as a cooling mechanism in the thermosphere and ionosphere

FAR IR emission by atomic oxygen fine structure transitions is considered an important cooling mechanism in the Earth's upper atmosphere and ionosphere as well as in several astronomical objects. The cooling rates so far have only been calculated theoretically on the basis of local thermodynamic equilibrium. No experimental or theoretical determination of the fine structure excitation or quenching cross sections for mutual neutral atomic oxygen collisions has been reported. We report here the first spectrometrically measured atomic oxygen 63-μm emission profile at thermospheric altitudes (90–180 km). An energy-averaged quenching cross section for the $O(^3P_1)$ level was deduced. The importance of the 63-μm emission as a cooling process for both the neutral thermosphere and the ionosphere is much less than predicted.

On 16 March 1977, at 2304 CET a liquid helium cooled far IR grating spectrometer was launched aboard a Skylark 7 rocket from Andoya, Norway, as part of the payload AI/II-PHA-F4D of the 'Polar High Atmosphere' rocket campaign (see ref. 1 for details). During the flight the geomagnetic field was moderately disturbed (200 nT). Measurements were taken in the wavelength interval of 45–125 μm.

Figure 1 shows preliminary absolute zenith intensities of the 63-μm line measured by this experiment (code name AB3). The data are compared with a model calculation by Kockarts and Peetermans[2] (KP1 and KP2). This model includes radiative transfer and is valid under the following assumptions: (1) the atomic oxygen is in diffusive equilibrium; (2) the fine structure level occupation densities obey a Boltzmann distribution at the local gas kinetic temperature, that is, local thermodynamic equilibrium (LTE) is assumed; (3) no additional non-thermal excitation processes are accounted for. Two curves from this model are shown in Fig. 1: curve KP1 assumes an atomic oxygen number density of $1\times10^{11}\ \text{cm}^{-3}$ at 120 km; curve KP2 is valid for a corresponding value of $5\times10^{10}\ \text{cm}^{-3}$. The exospheric temperature is 750 K for both curves, close to the exospheric temperature of 800 K at the time of the flight. At low altitudes the 63-μm line becomes optically thick. The agreement between the measurement and the model curve is quite good at these altitudes, taking into account experimental error (bar) and approximations used for the model calculation. At higher altitudes, however, the measured intensities are much lower and exhibit a much steeper altitude gradient than the calculated ones. Neutral gas densities, including atomic oxygen, were measured by a mass spectrometer during the upleg of the rocket trajectory (E. Hettmannsperger, P. Lämmerzahl and D. Krankowsky, personal communication). The slope of the measured atomic oxygen density profile does not show any substantial departure from a diffusive equilibrium density profile for a 800-K exospheric temperature. Despite local and temporal differences between the upleg and downleg trajectory, the model assumption of diffusive equilibrium seems satisfactory in the conditions of this experiment.

The steep gradient of the measured 63-μm line intensities can be understood if the atomic oxygen line is not in LTE. The atomic oxygen concentration in the ^3P_J state may then be described by

$$n_J = n(\text{O})\frac{f_J g_J \exp(-E_J/kT)}{\sum f_J g_J \exp(-E_J/kT)}\quad J=2,1,0 \qquad (1)$$

where $n(\text{O})$ is the total atomic oxygen number density, g_J the statistical weights $2J+1$ of level J, E_J the energy above the P_2 ground level, k Boltzmann's constant, T the local gas kinetic temperature, and f_J the deviation from a Boltzmann distribution. The functions f_J are determined as a function of altitude by solving the steady-state equation for the three fine structure level densities. The steady-state equation includes spontaneous and induced emission, reabsorption of radiation and collisional activation and quenching. A first approximation of the solution is obtained by neglecting any effects caused by collisional and radiative transitions to and from the $^3P_0$ level.

Two curves, NB1 and NB2 in Fig. 1, were calculated for a non-LTE distribution of the fine structure level densities. Curve NB1 was derived from the density and temperature conditions of the KP1 profile. Curve NB2 is valid for the corresponding conditions of the KP2 profile. The specific radiation intensity needed for solving the steady-state equation was derived from the measured 63-μm intensity in the optically thick altitude regime and was assumed to be altitude independent. Both curves fit the measured altitude gradient reasonably well. An energy-averaged quenching cross section of about $10^{-20}\ \text{cm}^2$ is adopted to produce these curves. Best agreement with the measured intensities is obtained with the profile NB1. Increasing the quenching cross section by a factor of 2 already causes a considerable discrepancy between measured and calculated profile gradients. Still lower cross sections are possible, however, as the curve approaches a radiation equilibrium profile. The value of $10^{-20}\ \text{cm}^2$ is therefore an upper limit at this early state of the data analysis.

Atomic oxygen fine structure levels may also be excited by electron impact. This process is thought to act as an important cooling mechanism for ionospheric electrons[3]. In this case electron densities and temperatures were measured simultaneously on the same payload (A. Dumbs and E. Neske, personal communication); atomic oxygen excitation by electrons was therefore included in a second step in the steady-state equation. The electron energy loss rate given by Dalgarno[4] was used and divided by a factor of 2 following a suggestion by Hoegy[5]. The 63-μm line intensities calculated for thermal and electron impact excitation in non-LTE conditions based on the profile NB1 are shown in Fig. 1 (NE1). The difference between the values of the curve NE1 and NB1 shows the effect of the additional electron excitation. It seems that the cross sections for electron impact excitation of atomic oxygen fine structure levels by Hoegy[5] are still too high by a considerable factor. The detailed evaluation of the interplay between thermal and electron excitation of the 63-μm line is now underway.

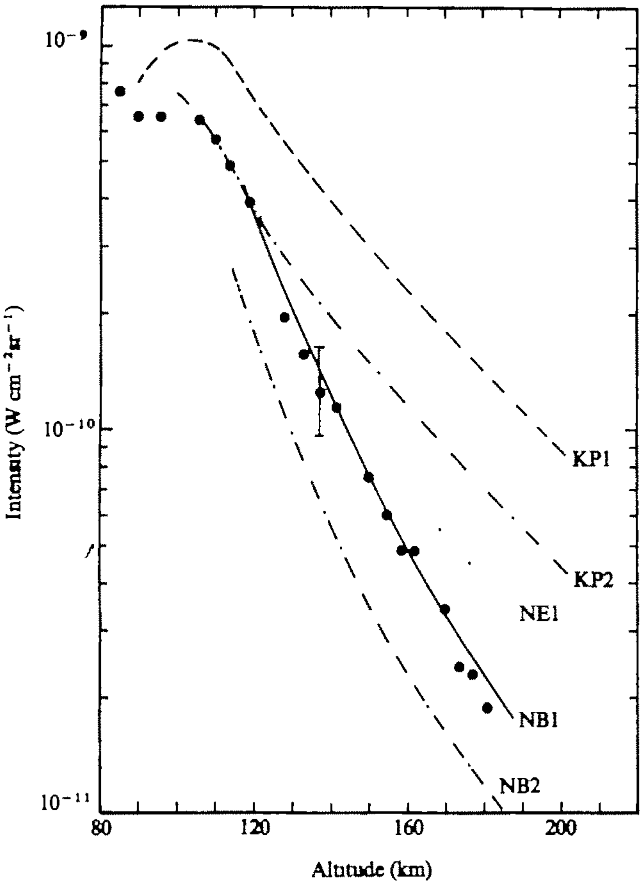

Fig. 1 Atomic oxygen 63-μm zenith intensities. ●, Individual data obtained during downleg of rocket trajectory; other labels, see text.

The preliminary 63-μm emission profile reported here has considerably lower emission rates than predicted and the importance of the 63-μm emission as a cooling process for the neutral thermosphere is much less than previously assumed. Measurements have enabled the determination of at least an upper limit of the fine structure quenching cross section for O–O collisions and the deduced value of 10^{-20} cm^2 is several orders of magnitude less than was previously assumed. The altitude dependence of the electron cooling rates as found experimentally[6] does not agree at all altitudes with the theoretical expectations for the energy transfer from electrons to neutral atomic oxygen directly or by ions. Lower 63-μm emission rates and lower electron to atomic oxygen excitation cross sections as described here would help to lessen this discrepancy.

Helium gas bubble lattices in face-centred-cubic metals

ION irradiation of metals with helium or hydrogen isotopes commonly results in the formation of microscopic gas bubbles. At very high doses, radiation blistering and related phenomena can cause severe damage to surfaces[1]. Much research has been stimulated by the need to find materials with acceptable erosion and gas loading properties for use in future controlled thermonuclear reactors. Bubble formation is also important in fission-reactor fuel technology and other applications[2,3]. The underlying bubble structure of face-centred-cubic (f.c.c.) metals has remained largely unknown, although much has been done on depth profiling light gases implanted to high doses (see, for example, refs 3–5). Inert-gas bubbles lying on a space lattice have been reported previously only for the body-centred-cubic (b.c.c.) metal molybdenum[6,7]. There have been many observations, mainly for b.c.c. metals, of the similar ordering of voids produced by particle irradiation[8,9]. The void lattice spacing is typically 5–10 times that found for bubbles (~5 nm). We report here on the bubbles produced in several f.c.c. metals by 30 keV helium-ion irradiation to a level just below the critical dose for blistering. A new result for this important class of metals is that the helium gas bubbles lie on a superlattice having an f.c.c. structure with principal axes aligned with those of the matrix.

Annealed polycrystalline targets electropolished to a high surface finish were irradiated at room temperature to a level of approximately 4×10^{17} He ions cm^{-2} with the ion beam normal to the surface. The main study was of copper, for which the mean projected range and r.m.s. spread in projected range, calculated using the Harwell version[10] of the computer code E-DEP-1 of Manning and Mueller, are 97 nm and 43 nm respectively. To ensure that the samples were all at approximately the same stage of bubble development, an ion beam having a lateral gradation in current density was used. Radiation blisters formed first where the current density was highest[3] and the region of the target which was close to blistering could be easily identified. Samples were taken from this area and thin sections containing the bubble layer prepared for transmission electron microscopy.

Bubbles in copper, typical of those observed for helium-ion irradiation at 300 K, are shown in Fig. 1. Considerable bubble alignment can be seen with dense-packed rows parallel to matrix {111} trace directions. Diffraction from the bubble array caused the splitting evident around the matrix reflections in the electron diffraction pattern of Fig. 2. The strongest reflections in the superlattice pattern are assigned (111) indices as they are in line with the (111) matrix spots and are in the positions expected for diffraction from the dense-packed planes seen edge-on as bubble rows in Fig. 1. The results show that the bubble-lattice is at least predominantly an f.c.c. structure aligned with the copper matrix. The bubble diffraction patterns for the matrix orientations [100], [111] and [112] support this conclusion. Alignment conforms, as expected, to crystallographic features in the

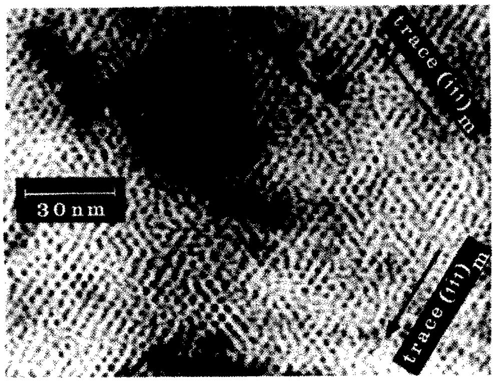

Fig. 1 Direct transmission electron micrograph of helium gas bubbles in copper following helium-ion irradiation to a level of $\sim 4\times10^{17}$ 30keV He ions cm^{-2} at 300 K. The electron beam is along [110] in the matrix and is normal to the plane of the bubble layer. The directions of the traces of the (111) matrix planes in the (110) plane are indicated. The bubble lattice constant, a_l, found from 380 measurements of inter-bubble spacing is 7.7 ± 0.8 nm.

copper; bubble rows run parallel to matrix slip traces and assume the twin-direction on crossing twin boundaries.

The lattice constant found, $a_l = 7.6\pm0.3$ nm, corresponds to approximately 10^{19} bubbles cm^{-3}. There is good agreement between the results both for samples from the same irradiation and for the several different copper targets used. The lattice constant based on diffraction from a given set of planes is consistent for the above orientations. There are, however, small but apparently significant differences between the different planes. For example, the {200} planes give a consistent value for a_l of 6.8 ± 0.4 nm. Some variations in structure are apparent and will be reported eslewhere. Direct micrographs at [110] show domains of good ordering typically of five inter-bubble spacings across with regions between of comparable size in which the ordering is less obvious.

The average bubble diameter found using a through-focus technique is 2.0 ± 0.5 nm. The ratio of lattice spacing to bubble radius is in the range of values found for void lattices[9]. This suggests there may be a common mechanism of lattice formation. If all the implanted helium is contained in bubbles of the size and separation measured here, then it can be estimated that the bubbles may be over-pressured by a factor of 5 or more. The difficulty is in relating helium pressure to atomic density at very high densities[11]. Over-pressure is a necessary element in a recent theory of blister formation[11]. The associated volume swelling is 5%; the swelling could be higher and the degree of over-pressure less if there were an additional large population of small gas bubbles below the resolution limit of the microscope (~1.5 nm for cavities in copper). We have been unable to detect this either in diffraction at 300 K or in direct microscopy on specimens heated to induce bubble growth. For this reason the existence of a significant population is thought to be unlikely. The bubble lattice seems to form only at high dose ($\gtrsim 2\times10^{17}$ He ions cm^{-2}), but once formed it is stable at temperatures up to approximately $0.3T_m$. Following blistering at 300 K, a bubble lattice with similar parameters has been seen here to survive in some blister caps as well as in the region between blisters.

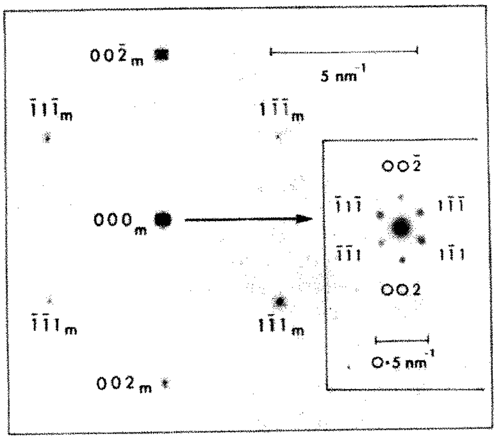

Fig. 2 A selected-area electron diffraction pattern from the specimen of Fig. 1. The electron energy is 100 keV. The matrix pattern is shown on the left and the superlattice diffraction pattern centred on the (000) transmitted beam is shown enlarged in the inset. In the latter slight changes in specimen tilt and translation have been made to obtain more uniform excitation. The value of a_l deduced from the separation of the (111) spots is 7.6 ± 0.3 nm.

Similar helium-bubble lattices are seen after irradiation at 300 K in the two other f.c.c. metals studied, nickel and AISI 321 (18Cr : 10Ni : Fe) austenitic stainless steel. The lattice constants based on diffraction from (111) superlattice planes are 6.6 ± 0.5 nm and 6.4 ± 0.5 nm respectively. At 300 K copper is above the vacancy mobility temperature while nickel and stainless steel are below. As in molybdenum, vacancy mobility does not seem to be a major factor in forming the lattice, at least in the limited range of low mobility covered by these metals. In this context it is interesting that considerable bubble alignment has been observed in the present experiments in proton-irradiated copper where the rate of vacancy production by the primary beam is a factor of 10 less than for helium-ion irradiation.

The reproducibility of the results suggests that bubble lattice formation could be a common feature of high-dose inert-gas implantation in annealed f.c.c. metals at low temperature. P.B.J. thanks The Nuffield Foundation for financial assistance.

Crown ether intercalations with phyllosilicates

IT has been discovered in the past decade that some macrocyclic polyethers (crown ethers) act as ligands to form stable complexes with salts of numerous metals. These are the first synthetic compounds able to coordinate to alkaline cations[1-3].

0028–0836/78/0276—0596$01.00

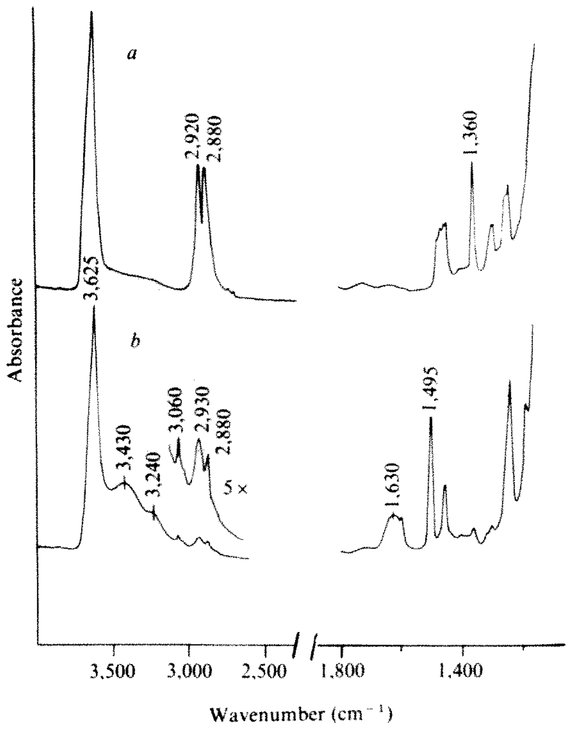

Fig. 1 Infrared spectra of Ba-montmorillonite treated with a methanolic solution of: *a*, 15-crown-5; *b*, dibenzo 18-crown-6.

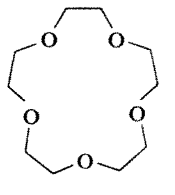
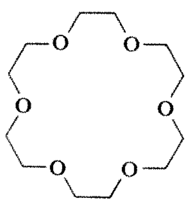
The cyclic structure of the crown ethers creates a circular cavity of oxygen atoms to which the cations coordinate. The diameter of this cavity as well as the relative size of the cation, determine the stability of the resulting complexes, and the cationic selectivity depends on it. The most studied crown ethers are derived from so called 15-crown-5 and 18-crown-6:



15-crown-5



18-crown-6

We have shown experimentally and report here that the crown ethers are able to intercalate between the layers of the 2:1 phyllosilicates, saturated with alkaline or alkaline-earth cations, showing an unusual stability. The complexes were obtained mainly by immersion of homoionic montmorillonites (Wyoming bentonite), in different solutions of crown ethers. Hectorite and vermiculite were also tested with positive results.

Many neutral organic substances, such as alcohols, ketones, phenols, and aromatic hydrocarbons, can intercalate the interlamellar space of clays of the smectites group[4-5]. Generally, the fixation of these compounds is due to their interaction with the exchangeable cations, which balance the deficit of charge of the silicate layer. Nevertheless, the stability of those complexes is relatively low, especially in the presence of alkaline cations. Water molecules also easily replace the organic ligands, by exposition to atmospheric moisture.

The coordination between the interlamellar cation and the crown ether, can be shown by the UV spectra of montmorillonite treated by dibenzo-18-crown-6. The band at 275 nm, due to the aromatic ring, is displaced in the Na-, K-, and Ba-montmorillonite complex, to 285 nm. A shift of 6 nm has been observed in complexes of the same crown ethers with different inorganic salt solutions. The shift was explained by the bathocromic effect of the cation associated to the aromatic ring[1].

Table 1 Values of the increase in the basal spacings (Δd) in homoionic montmorillonites (M–K^+, M–Na^+, M–Ba^{++}) treated by some crown ethers.

Crown ethers	Δd_{001} (Å) M–Na^+	 M–K^+	 M–Ba^{++}
12-crown-4	8.1	4.4	6.6
15-crown-5	4.0	4.4	8.0
18-crown-6	6.3	4.4	3.9
dibenzo-18-crown-6	8.9	7.9	7.7
dibenzo-24-crown-8	8.2	9.0	7.1

The basal spacing (d_{001}) of the anhydrous montmorillonite is 9.6 Å.

The IR spectra show that the coordination of the crown ether with the interlamellar cation produces a displacement of water molecules which originally belonged to the sphere of coordination of the cation. Figure 1*a* shows the IR spectrum of the Ba-montmorillonite complex 15-crown-5 where the H_2O bands have disappeared. However, when crown ethers of a larger size are intercalated, the steric effect prevents the complete association to the cations, and the water molecules are not completely displaced. Figure 1*b* shows the spectrum of Ba-montmorillonite/dibenzo 18-crown-6 complexes, in which the bands at 3,430 and 3,240 cm^{-1}, ν(OH) stretching, and the 1,630 cm^{-1}, δ(HOH) bending are visible but less intense. The displacement of water molecules is irreversible, in contrast with the already mentioned complexes with other neutral organic molecules.

The intercalation of the crown ethers in phyllosilicates can be also followed by X-ray diffraction. In most cases the increase of the basal spacing are either 4 or 8 Å (Table 1), which may be interpreted as monolayer or two-layer complexes respectively. The macrocyclic ligands are arranged parallel with respect to the silicate layers, in agreement with the thickness of the crown molecules. The 001 reflections present integral orders, suggesting a reasonable crystalline order for most of the montmorillonite complexes such as 15-crown-5,18-crown-6 and its derivatives. In some cases interstratifications are obtained.

The high stability of these new complexes is the most interesting feature: the crown ether is not desorbed by water treatment, organic solvents or salt solutions. In salt solutions the complexes can maintain the cation exchange capacity of the original mineral. Besides, thermal treatment is not able to desorb the crown ethers, as shown by the exothermic peak around 350 °C, observed by DTA.

Note added in proof: Intercalation complexes of phyllosilicates saturated with alkaline, alkaline-earth or transition metal cations have been recently prepared in our laboratory with polyoxadiazamacrobicyclic ligands ('cryptands').

Measurement of thermal maturation of petroleum by proton magnetic resonance spectroscopy

THE processes of petroleum generation and maturation have been shown to depend on the thermal breakdown of organic material contained in the sediments as the temperature increases due to increased burial depth[1,2]. Measurement of the degree of thermal alteration of the organic matter in shales and other potential petroleum source rocks is therefore of fundamental importance to petroleum exploration. The most common methods of estimating the degree of thermal alteration are based on measurements of the residual insoluble organic material in rocks. Some of the more common methods use changes in the chemical composition of the kerogen[2], electron spin resonance[3], kerogen coloration[4] and vitrinite reflectance[5]. The method reported here is based on measurements on the soluble aromatic hydrocarbons extracted from the sediments. As the aromatics are represented in both the source rock and reservoir petroleum they may eventually provide a useful medium for comparing the thermal history of reservoir and source rock hydrocarbons. This method uses well established chemical techniques and provides a simple quantitative measure of thermal maturation by measuring the percentage of aromatic protons in the aromatic fraction of petroleum.

Samples of petroleum-bearing shales and siltstones were obtained from drilling operations in the Carnarvon Basin of Western Australia. Samples from different locations and depths of a uniform sequence of Cretaceous marine sediments were studied. Geochemical data for the samples are shown in Table 1. Each sample was crushed and the soluble organic material was extracted with methylene chloride : methanol (20 : 1) under the influence of ultrasonic vibration. After careful distillation of the solvent at atmospheric pressure the residue was chromatographed on silicic acid. Consecutive fractions were eluted from the column with pentane, ether and methanol. The fraction eluted with ether was retained as aromatic hydrocarbons and analysed by proton magnetic resonance spectroscopy.

The signal from the aromatic protons (δ 6.7–7.9) was integrated and expressed as a percentage of the total proton integral. This value, the percentage of aromatic protons in the aromatic fraction, will be referred to as the PAP value of an oil or extract.

Although thermal evolution of organic matter depends on both time and temperature, the time factor has been taken as constant for all samples and the PAP values have been plotted against the present sediment temperatures (Fig. 1). The assumption that each set of samples has a similar thermal history is supported by geological evidence that subsidence occurred at each location in the basin over approximately the same time interval, and that the sediments are now at their maximum depth of burial[6]. Samples from three different wells over a temperature range of 60 °C show a regular increase in their PAP value as the temperature increases. This correlation of temperature and PAP value is attributed to the effect of thermal processes on the petroleum and is supported by pyrolysis studies of low maturity hydrocarbons. Figure 2 shows PAP values plotted against time for petroleum which had been subjected to pyrolysis at 300 °C for various times. In these experiments, the low maturity petroleum was contained in a matrix of shale and pyrolysed in evacuated glass tubes. Blank experiments, without added petroleum, showed that the contribution from pyrolysis of hydrocarbons already present in the shale was negligible.

These experiments showed that the changes in the PAP value which result from pyrolysis of an immature petroleum are similar to those which are observed in nature as the sediment temperature increases. It is therefore reasonable to conclude that the variation in PAP value of sediment extracts reflects the level of maturity of organic material in the sediment.

Vitrinite reflectance data for one set of samples are shown in Table 1. Both the PAP and vitrinite reflectance values are consistent and indicate that the organic material has undergone

Table 1 Geochemical data

moderate levels of thermal maturation. The samples investigated differed in their CPI values and in the proportions of *n*-alkanes and napthenes. This suggests that this new technique is useful for samples containing a range of chemical types; however, further work is required to fully assess the validity of the technique for a greater range of kerogen types.

This technique may be a useful supplement to existing methods of measuring thermal maturation as it provides a sensitive measure over the small but important temperature range where liquid petroleum is generated and matures.

Oxidation state of plutonium in the Irish Sea

SEVERAL of the chemical parameters needed to understand the distribution and behaviour of plutonium in the aquatic environment have not been fully investigated in the field. We consider here two of the more fundamental of these parameters: (1) the oxidation state(s) of the plutonium present in seawater; and (2) the extent to which each oxidation state is associated with suspended particulate matter. A widely accepted analytical technique is adapted to separate the two oxidation states expected to show a high affinity for particulate matter, Pu(III) and Pu(IV), from the more soluble pair, Pu(V) and Pu(VI), and is applied to a series of seawater samples. It was found that in the area studied, generally >75% of the plutonium in solution, and <10% of the plutonium on particulate matter, was Pu(V+VI); consequently the distribution coefficients for Pu(III+IV) exceeded those for Pu(V+VI) by more than two orders of magnitude.

Based on comparisons with natural chemical analogues, the different oxidation states of plutonium are expected to show markedly different biogeochemical properties. Uranium and thorium, for example, are very similar in basic chemical properties to Pu(VI) and Pu(IV) respectively. Although the crustal abundances of the two elements are similar, uranium is present in open ocean seawater at a concentration 10^4 times higher than thorium[1]. Similarly, differences in direct biological accumulation are observed and, as Cherry and Shannon state[2], "thorium must, clearly, be taken up more efficiently by marine organisms than is uranium".

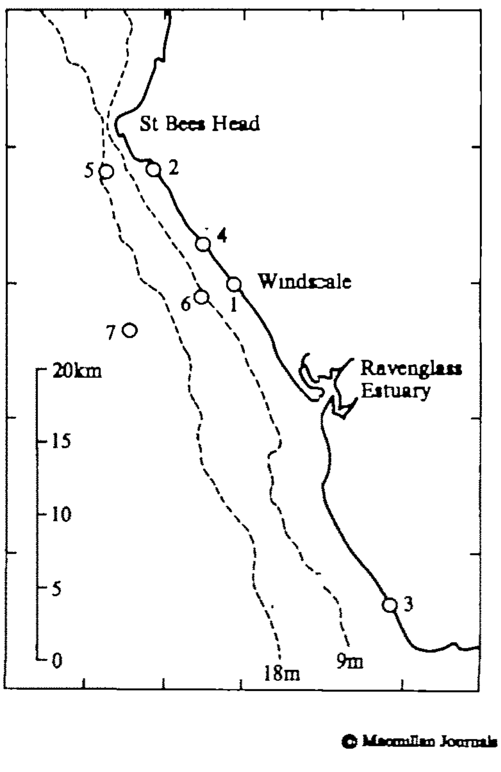
The potential importance of oxidation state in determining the environmental chemistry of plutonium has frequently been stated[3–6]. Analytical procedures to separate the oxidation states have been published[7–8] and applied to laboratory samples. Laboratory experiments have also used plutonium, in initially specified oxidation states, to test the stability[9], biological availability[10–13] and attachment to sediments[14] of various oxidation states. These observed biogeochemical differences between the chemical analogues of plutonium combined with the differences observed between actual plutonium oxidation states in laboratory experiments emphasise the importance of establishing the oxidation state(s) of plutonium found in the environment. However, we know of no information published regarding the actual oxidation states of plutonium found in natural seawater.

The BNF reprocessing plant at Windscale, Cumbria, discharges plutonium into the Irish Sea through a submerged pipeline terminating 2.4 km offshore. This release supports plutonium concentrations of about 1 pCi l^{-1} in filtered seawater near the discharge[15] and provides an excellent experimental area in which to study the oxidation state(s) of plutonium.

Eight seawater samples were collected from the seven locations marked on Fig. 1 during the summer of 1977. Shoreline samples were collected from water depths of ~0.5 m; offshore samples were collected either within 1 m of the surface or within 1 m of the seabed.

For each sample, the association of different oxidation states of plutonium with suspended particles was determined by measuring the concentration of each oxidation state in subsamples processed: (1) without filtration; (2) after filtration through a 0.22 μm Millipore membrane filter; and (3) in five of the eight samples after filtration through both 0.22 and 0.025 μm Millipore membrane filters. The method used for oxidation state differentiation was an adaption of the classical separation of Pu(III) and Pu(IV) from Pu(VI) by the co-precipitation of the former pair on a rare earth fluoride[16]. An internal measurement of the completeness of separation was provided by adding tracers of the relevant oxidation states to each sample and then monitoring the degree of separation of these tracers. Each subsample was made 0.8 M in HNO_3, 0.25 M in H_2SO_4, 0.5 mM in $K_2Cr_2O_7$ and 0.7 mM in $Nd(NO_3)_3$. Unfiltered subsamples stood overnight at this stage to allow exchangeable plutonium to leach from the particles before they too were filtered. Initial observations had shown that the leachate constituted >90% of the total plutonium originally on the particulate matter. Sufficient HF was added to raise the total fluoride concentration to 0.25 M and the resultant NdF_3 precipitate was removed by filtration. $(NH_4)_2SO_4 \cdot FeSO_4 \cdot 6H_2O$ was added to the filtrate

Fig. 1 Location of water sampling stations.



(5g l^{-1}) which then stood overnight to complete the reduction of any Pu(VI) in the sample. NdF_3 was again precipitated by the addition of 100 mg of Nd per litre and removed by filtration. The method was considered sufficient to disrupt any complex ions—organic or inorganic—initially present in the sample. The plutonium in each NdF_3 precipitate was purified by routine[17] techniques of anion exchange and individual plutonium isotopes were determined by α-spectrometry using silicon surface barrier detectors.

Completeness of the oxidation state separation and chemical yields were determined from the recovery of two isotopic diluents, ^{236}Pu(VI) and ^{242}Pu(IV), added to each subsample as soon as possible after collection (and after filtration for filtered subsamples). Each tracer was isotopically pure and contained >99% of its plutonium in the specified oxidation state. Overall chemical yields exceeded 80% and the separation of the two tracers typically exceeded 97%, even for the unfiltered subsamples. This maximum 3% deviation includes any plutonium which changes oxidation state during the analysis as well as any which simply carries on the incorrect precipitate.

Any Pu(III) or Pu(V) initially present would be rapidly oxidised by the $Cr_2O_7^{2-}$ to Pu(IV) and Pu(VI) respectively and would be indistinguishable from the original Pu(IV) and Pu(VI). The oxidation of Pu(IV) by dilute $Cr_2O_7^{2-}$ is an extremely slow process and was unimportant during these experiments. In a well oxygenated, high *p*H system, such as surface seawater, the higher oxidation state in both the Pu(III):Pu(IV) and Pu(V):Pu(VI) couples were assumed to be the more likely and subsequent results are reported as Pu(IV) and Pu(VI). A more detailed description and discussion of the method will be presented elsewhere.

The Pu(IV) and Pu(VI) concentrations, tabulated by particle size class in Table 1, were calculated for each sample using the plutonium concentrations measured in the subsamples. The concentration of plutonium on particles >0.22 μm was the numerical difference between the concentrations measured in the unfiltered subsample and the 0.22 μm filtered subsample. The concentration on particles between 0.025 and 0.22 μm was the difference between the concentrations measured in the two filtered subsamples. The concentration in water passing the 0.025 μm filter (0.22 μm in the initial three samples) is presented directly. These results indicate that plutonium retained on the filters is predominantly Pu(IV) and that plutonium passed in the filtrate is mainly Pu(VI). Simply filtering these samples provided a fair separation of the oxidation states, a feature which could prove useful in estimating the oxidation state present in previous measurements. Little of the plutonium of either oxidation state which passes a 0.22 μm filter is removed by the 0.025 μm filter, suggesting that the plutonium may be in true solution and not simply attached to very small particles. Furthermore, the ratio of Pu(VI) to Pu(IV) in solution, particularly for the offshore surface samples, is sufficiently constant to suggest first that the two are at or near oxidation–reduction equilibrium, or second, that the rate constants governing the approach to this equilibrium are slow compared with the initial rate of dispersion of Windscale effluent in the sea.

Assuming that there are heterogeneous exchange reactions for both Pu(IV) and Pu(VI) between seawater and suspended particulates, distribution coefficients (K_d = pCi kg^{-1} in particles/pCi l^{-1} in water) for each oxidation state as well as for total plutonium were calculated. These K_d values for each sample are given in Table 2. As the composition of suspended particulates is extremely variable, it is not surprising that the distribution coefficients are far from constant. However, the general trends are unmistakable. Although the distribution coefficients measured for total plutonium are typical of values previously reported for the Irish Sea[15] and other systems[18], in these samples the distribution coefficients for Pu(IV) exceed those of Pu(VI) by factors of up to 1,000. This is consistent with the behaviour of the chemical analogues, Th(IV) and U(VI).

Because of this large difference in the K_d value, the initial distribution of plutonium between soluble and particulate phases (including the seabed) in the sea should be highly dependent on the ratio of oxidation states in the source material. It has been observed at Windscale that approximately 95% of the plutonium discharged is rapidly removed to the seabed and that the remaining 5% is removed from the area by water transport in a manner indistinguishable from the transport of the soluble isotope ^{137}Cs (ref. 15). From the above data we suggest that this 5% is largely Pu(VI) and that its ability to remain in solution is not surprising. Measurements of oxidation state ratios in Windscale effluent as well as at various distances from Windscale (and by inference at various times after release) are in progress. Nevertheless, the results of the present study have shown: (1) that plutonium can exist in natural seawater (at least in the one area for which data are available) as a mixture of

oxidation states; and (2) that it distributes between the soluble and particulate phases in a manner dependent on this mixture. It is clear that a knowledge of the changes in oxidation state undergone by plutonium will be important in understanding the ultimate fate of this element in the environment.

Catastrophic events in a surface mixed layer

THE formation and evolution of mixed layers in the surface waters of the oceans are important in many fields of study and much effort has been expended towards the development of predictive models of the wind-mixed surface layer[1,2]. These models parameterise small-scale high-frequency turbulent mixing processes, which are difficult to measure, in terms of more easily observed variables such as the wind stress. Because this parameterisation depends on hypotheses about the character of the turbulent mixing which dominates the transport of heat and momentum, it is vital to have a realistic concept of the turbulent processes in active mixing layers. It is often assumed that a major source of turbulence at the base of the mixed layer is the shear between the mean currents in the mixed layer and those in the thermocline. Simple shear turbulence of this sort often may be described by a flux-gradient relationship[3]. We have now found that although a flux-gradient description is adequate most of the time at the base of an actively mixing layer, during a storm isolated and relatively rare large-scale catastrophic mixing events, which cannot be described by a flux-gradient relation, can dominate transport. Although these catastrophic events occur infrequently, the vertical heat transport associated with them can dominate the continuous transport associated with flux-gradient processes.

While taking microstructure profiles at Ocean Station P (50°N, 145° W) during August 1977, we observed a storm of substantial intensity (maximum wind speed 20 m s^{-1}) which lasted 48 h. Temperature profiles were taken from the RV Oceanographer with the microstructure profiler (MSP)[4], a winged instrument which falls freely through the water measuring temperature, pressure, and conductivity. Sampling on 23 August began at 0415 GMT, about 24 h into the storm. During an 8-h sampling interval, 22 casts were made, each lasting about 5 min, with 10 to 60 min elapsing between casts. Since the vessel was by no means motionless during the storm, each cast must be considered as an observation of an independent realisation of the processes involved. No clear evidence of systematic mean temporal changes in the profiles can be seen during the sampling. Observation of mixed layer deepening during this period was obscured by 5–10 m amplitude internal waves.

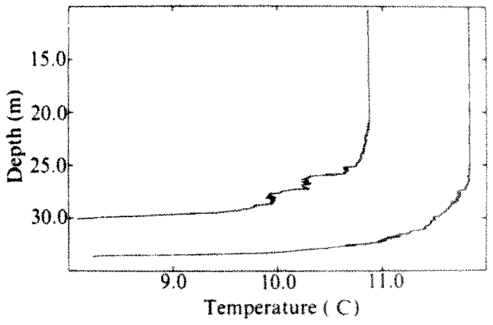

Fig. 1 Temperature profiles typical of small-scale, shear-generated turbulence at the mixed layer base. Left profile is offset 1 °C to the left. Thermocline depth difference is due to internal waves.

Most profiles on 23 August show the temperature to be nearly constant to within a few metres of the seasonal thermocline (Fig. 1). At the base of the mixing layer, a rather smooth transition from mixed layer to thermocline is usually seen; temperature structures seen here usually have a length scale less than several centimetres. This is characteristic of small-scale, shear-induced turbulence.

Two of the August 23 profiles are remarkably different (Fig. 2). They show events in which large masses of cool water are swept into the warmer isothermal layer above. In addition, two other profiles show large-scale disturbances at the mixed-layer base (Fig. 3). These may well be incipient events, in which the unstable mass of water has not yet separated from the water below.

Information regarding the vertical motion of these features can be obtained from the instantaneous fall rate of the probe. A winged vehicle with large drag coefficient responds rapidly to fluctuations in the local water velocity,[5] and drops at a constant speed with respect to the water in its immediate vicinity. (If the probe's fall rate is inferred from the pressure record, the measured speed of descent is insensitive to vertical velocities associated with surface waves.) On encountering the sharp

0028–0836/78/0276—0601$01.00

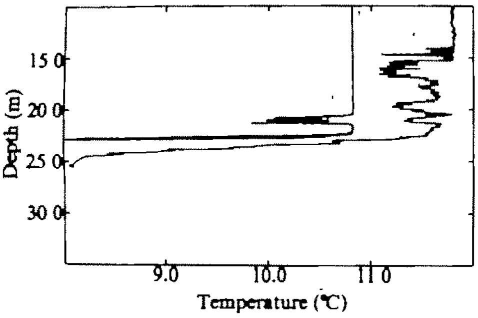

Fig. 2 Temperature profiles showing large-scale catastrophic mixing events. Event in left profile is very young, while event in right profile is older and in a state of collapse.

inversion in the profile on the left in Fig. 2, the probe abruptly ceased to fall relative to the surface, indicating that the water surrounding the probe was moving upwards at a speed comparable to the probe's vertical velocity, 12 cm s^{-1}. Thus, this water mass arrived from below only seconds before the observations, a conclusion borne out by the extremely large temperature gradients at its upper and lower edges. The event shown in the profile to the right in Fig. 2 was moving downwards at 5 cm s^{-1}, indicating that this water mass is older and in a state of collapse, consistent with the convoluted, somewhat diffuse character of its boundaries. The 'incipient' events in Fig. 3 each have an upward velocity of 2–3 cm s^{-1}.

The importance of the catastrophic events to mixed layer dynamics is revealed by a comparison with the more ordinary flux-gradient shear turbulence. An estimate of the heat flux at the base of the layer in the absence of large-scale mixing events is modelled as $H = -K_z \partial\bar{\theta}/\partial z$ where K_z is estimated from the Cox number[6] (the mean square temperature gradient normalised by the square of the mean gradient). In the absence of large events the heat flux at the base was of the order of 10^{-3} cal $\mathrm{cm}^{-2}\,\mathrm{s}^{-1}$.

The heat flux attributable to catastrophic events can be described by the free-turbulence estimate $H = K_e \Delta\theta/l$, where K_e is estimated from Richardson's law of diffusion as $1/2\varepsilon^{1/3}l^{4/3}$, ε is the rate of dissipation of mechanical energy per unit mass, l is the size of the disturbance, and $\Delta\theta$ is the temperature difference between the mass and its surroundings. The heat flux is then $H = 1/2\varepsilon^{1/3}l^{1/3}\Delta\theta$, weakly dependent on ε and l and strongly dependent on $\Delta\theta$. The dissipation rate may be estimated from Fourier analysis of the temperature gradient by finding the Batchelor scale, the smallest length scale at which temperature fluctuations are appreciable. Lower bound estimates of ε, l and $\Delta\theta$ lead to a lower bound heat flux for a 'typical' event of 0.3 cal $\mathrm{cm}^{-2}\,\mathrm{s}^{-1}$. Weighting the single-event heat flux by the probability of occurrence during the sampling period (0.1–0.2) yields a lower bound of 0.03 cal $\mathrm{cm}^{-2}\,\mathrm{s}^{-1}$ for an average heat flux. Thus the flux-gradient heat flux is dominated by the heat flux due to catastrophic events despite their rarity.

The energy available for changing the potential energy of the water column by deepening the mixed layer is the difference between the energy produced by turbulence and the energy dissipated by viscosity. Most of the energy produced by simple shear-stress is dissipated; thus this process is inefficient in accomplishing mixed layer deepening. Large-scale mixing events can, however, cause large rapid transfers of kinetic energy directly from the mean flow through interaction with internal waves[6], and thus be very efficient for mixed layer deepening. Instabilities in general are triggered when some dynamically important parameter, such as a Richardson number, reaches a threshold value. During a second milder storm on 31 August, apparently no threshold was reached, for no overturning events were found. We might therefore expect that realistic parameterisation of mixed layer dynamics in strong storms should include a threshold for the occurrence of catastrophic mixing events.

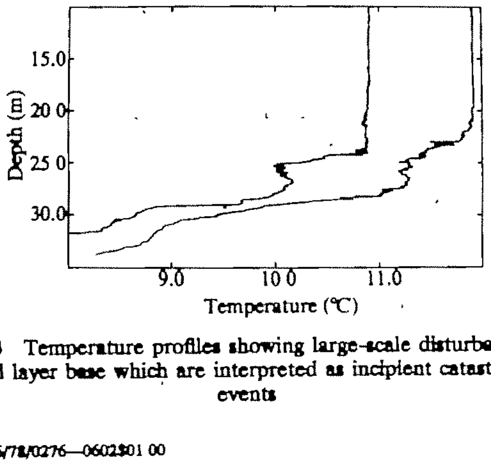

Fig. 3 Temperature profiles showing large-scale disturbance at mixed layer base which are interpreted as incipient catastrophic events

^{230}Th/^{234}U age support of an interstadial sea level of −40 m at 30,000 yr BP

THE position of sea level about 30,000 years ago—in the Paudorf interstade in Europe[1] and the Plum Point interstade in northeastern America[2]—is disputed, estimates varying from above present sea level to ~50 m below it. The disagreement is due partly to ^{14}C dating problems, and partly to stratigraphic errors and incorrect tectonic assumptions[3]. We now confirm a previous estimate[4–6] of −40 to −42 m made from Huon Peninsula, New Guinea, and give new ^{230}Th/^{234}U data which support previous ^{14}C results.

Raised coral terraces at Huon Peninsula contain more late Quaternary reefs than similar formations elsewhere (such as in Barbados[7] and Timor[8]) because of higher uplift rates, and are the basis for the palaeo-sea level curve for the last 0.25 Myr given in ref. 9. We are concerned with Huon terrace II dated previously by ^{14}C at 28.5 ± 0.6 kyr (mean of two determinations[5] with seawater ^{14}C correction[10] subtracted). The ^{14}C dates are from massive clams, *Tridacna gigas*, which show very little inversion from aragonite to calcite and which are microscopically indistinguishable from *Tridacna* specimens known to be beyond the ^{14}C dating limit and which are measured as containing zero ^{14}C—hence the result of 28.5 kyr has been argued as being a satisfactory ^{14}C age estimate[5]. However, because of ^{14}C dating uncertainty for old shell samples reservations have been held about this result, in the absence of confirmatory ^{230}Th/^{234}U measurements[6].

A specimen of unaltered coral, *Favia speciosa*, collected from the crest of Huon reef II and Blucher Point (147° 40′E, 6° 10′S), 18 m above sea level, yields the following U-series results: U-content = 2.62 p.p.m., $^{234}\mathrm{U}/^{238}\mathrm{U} = 1.2 \pm 0.02$, $^{230}\mathrm{Th}/^{234}\mathrm{U} = 0.25 \pm 0.02$, age estimate = 31.0 ± 2.5 kyr. We believe that this reef crest is time-equivalent with that from which the ^{14}C dates were obtained (at 147° 37′E, 6° 7′S), based on continuous reef-tracing between the two sites. Analytic methods are explained in ref. 8.

We consider that these results confirm an age-estimate of 28.5 to 31.0 kyr for Huon reef II. In the context of rapidly rising Huon Peninsula, the associated palaeo-sea level must be estimated by subtracting (age × uplift rate) from present elevation of reef II. For this, Chappell[5] used a nonlinear uplift rate model; Bloom *et al.*[6] used a linear model. Reef II results differ little between these two models and indicate a paleo-sea level of −40 to −42 m. The structure of reef II indicates sea level rise before growth of the dated crest; a subsequent fall to about −140 to −150 m before post-glacial transgression has been interpreted from young submerged terraces and reefs[5]. A low sea level around −150 to −160 m, relative to this part of the globe about 17,000 years ago, is supported by dated submerged terraces off northern Australia[11,12].

These sea-level changes conflict with ice volume variations estimated from ^{18}O analysis of deep sea cores. Figure 1 compares Huon Peninsula sea levels for the past 45 kyr (refs 8, 9), with ^{18}O curves from Panama Basin core V19-28 (ref. 13) and Caribbean core P6304-9 (ref. 14) using the chronology of Shackleton and Opdyke[15] and Shackleton and Matthews[16]. Also shown are ^{14}C-dated variations of the southern margin of the Wisconsinan ice sheet[2]. Correlation of Huon Peninsula sea levels seems to be better with the ice margin changes than with the ^{18}O records. Note, however, that the ice margin curve is not zero-referenced, because the parameter discussed here is ice volume, which is very difficult to estimate before 17 kyr because of uncertainty about previous ice margin patterns[2,17].

Fig. 1 Sea levels relative to Huon Peninsula, δ^{18}O variations in Caribbean and central Pacific surface waters, and migration of southern margins of Laurentide ice sheet. Note that deep-sea core chronologies are based on interpolation[15] and may not strictly be comparable with the sea level and ice margin chronologies.

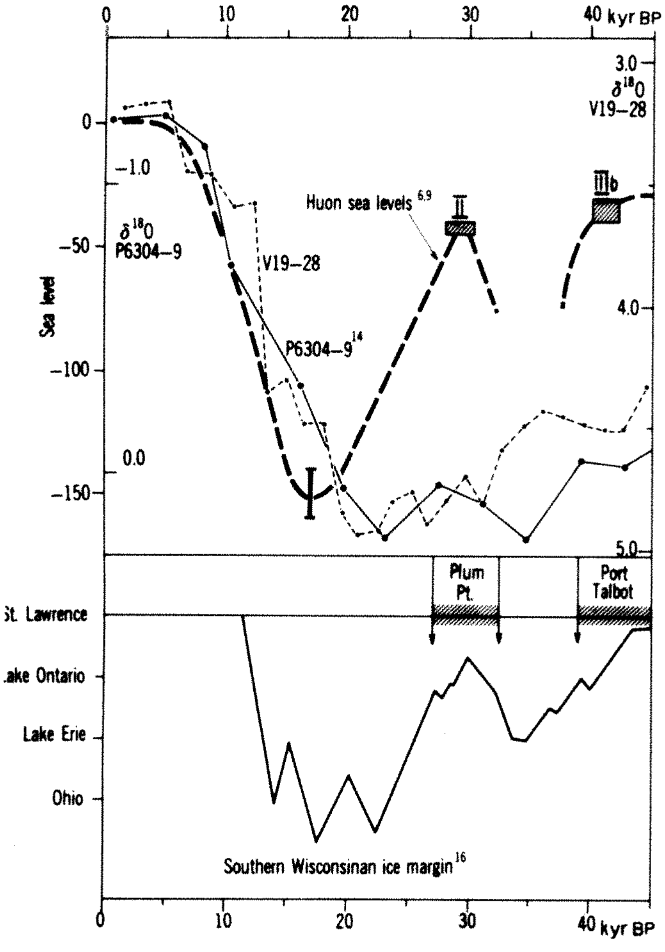

Table 1 Comparison of ^{230}Th/^{234}U and ^{14}C ages

Site	Ref.	C age (kyr)	No. of determinations	Th/U age (kyr)	No. of determinations
Huon P.	10	6.76	4	5.8	2
Huon P.	10	7.64	4	9.4	4
Gt Barrier Reef	11	13.7±0.2	2	17.0±0.8	2
Huon P.	This work	28.5±0.6	2	31.0±2.5	1
Huon P.	5, 6	35.6±1.5	2	40±3.0	4

Two factors damp the ^{18}O ice-volume signal in deep sea cores—seabed mixing processes, and variation of average ^{18}O content of the icecaps themselves[9]. However, the discrepancy for reef II, as well as for reef IIIb (ref. 5) (Fig. 1), is so large that one of the following three conditions must apply:

(1) Sea level relative to Papua New Guinea and northern Australia was no lower than about −75 m instead of the −150 m interpreted from dated submarine reefal terraces.

(2) A non-eustatic factor has affected the Huon Peninsula sea-level curve—either highly nonlinear tectonics, or hydro-isostatic processes greater than previously calculated[18,19], or some other process such as geoid changes[20].

(3) The δ^{18}O records are significantly smoothed by seabed mixing processes, reducing amplitude of peaks of less than ~10 kyr. Cores with higher sedimentation rates such as V19-28 show more variation than lower rate cores (compare V28-238)[15], and cores with yet higher rates may well offer a good test of our sea level curve.

Finally, we wish to comment on ^{14}C and ^{230}Th/^{234}U chronologies. Table 1 lists comparative data from several reefs—many from the same specimens—from ~6 to 45 kyr, ^{230}Th/^{234}U results beyond 6 kyr consistently show greater ages than ^{14}C. In the Holocene range the ^{14}C ages are more 'accurate' in terms of geochemical equivocations; however, they are well known to appear younger than true age due to past variation of atmospheric ^{14}C production. Concerning older examples in Table 1, corroboration seems to come from recent thermoluminescence dates from archeological materials ~30 kyr old, which like our reef II results, appear similar to ^{14}C dates from the same sites[21,22]. The problem of minor ^{14}C contamination in samples beyond ~30 kyr is difficult to eliminate, although we note that our ^{230}Th/^{234}U age for reef II is very close to the ^{14}C age of the Plum Point Interstade climax (Fig. 1), suggesting that the two chronologies become close at that time.

Eastwards migration of the Tuscan anatectic magmatism due to anticlockwise rotation of the Apennines

AT the northern apex of the Tyrrhenian Sea, two mountain chains face each other displaying opposite vergence: the Corsican alpine chain and the Northern Apennines (Fig. 1). The Corsican alpine chain consists of both oceanic and continental nappes transported towards the West which are assumed to have derived from the peeling off of European, Tethyan and African (Austroalpine domains) lithosphere sectors. The age of metamorphism and orogenic transport towards the European foreland is mainly Cretaceous–Palaeogene. We present here an interpretation of the available data on post-collision continental anatectic magmatism in the Tuscan province (Italy) in the light of geodynamic evolution of the Tyrrhenian Sea.

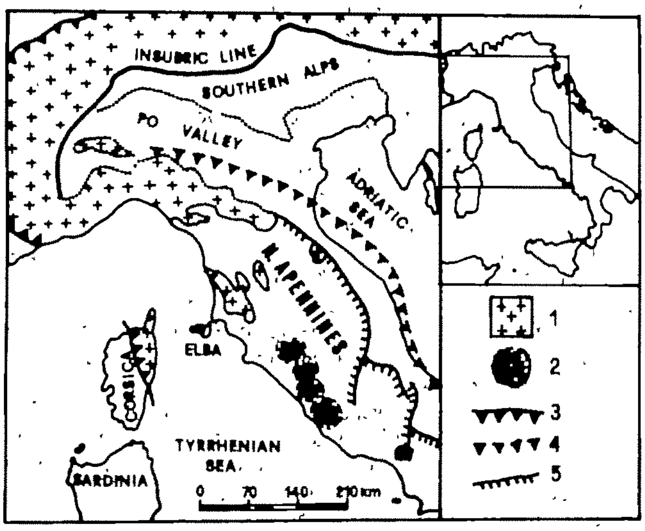

Fig. 1 Tectonic sketch map of northern Italy. 1, Palaeogene and Neogene Europe-verging Alpine nappes; 2, main upper Tertiary–Quaternary volcanoes; 3, European front of the Alpine chain; 4, front of the Apennines; 5, front of the carbonate units in the northern and central Apennines.

The northern Apennines consist of east and northeastwards transported continental nappes peeled off from the African (Insubric–Apulian domains) litosphere sector. Here, the age of metamorphism and orogenic transport is mainly Neogene. The Ligurian nappes, considered to represent slices of oceanic crust[1], are interpreted here as part of the Cretaceous–Palaeogene Europe-verging Alpine chain. During the late Oligocene and early Miocene they partially overthrust as a whole on to the Insubric domains that in Neogene times formed the Africa-verging Apennine chain (Fig. 2).

Extensive magmatic activity (the Tuscan province) developed between Corsica and Tuscany, within the strongly deformed belt marking the collision zone between the two chains. The crustal anatectic origin of this magmatic province is indicated both by petrological evidence (xenocrysts of quartz, cordierite and sometimes sillimanite, corundum normative composition[2] and isotopic data (high ^{87}Sr/^{86}Sr ratios[3,4] high δ^{18}O (ref. 5). Absolute age determinations range from 8.5 on Elba Island in the west to 0.43 Myr in Mt Amiata in the east[4,6] (Fig. 3).

The deep crustal structure in this area is controversial. The interpretation of gravimetric data[7] suggests crustal thicknesses under western Tuscany of $\sim$25 km. This value is too small for the root zone of a Neogene mountain chain, which implies that the crust here has been thinned and rifted after continental collision. A new interpretation has been proposed based on seismic results and the best fitting of seismic, gravimetric and magnetic data[8,9]: according to this model, the area between Elba and western Tuscany is characterised by the existence of two crust–mantle boundaries, the first 15–25 km deep and the second 45–50 km deep. The body between the two discontinuities might contain continental crustal material, a possible source for the observed magmatism. Accepting crustal thicknesses around 45–50 km the western Tuscany area might correspond to a normal or slightly thinned root zone for the northern Apennines.

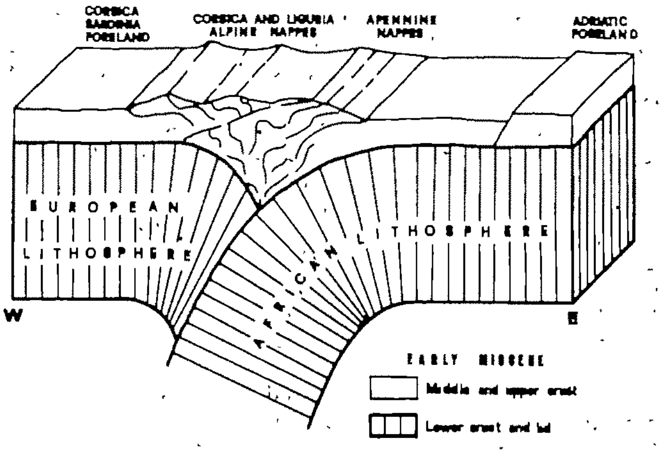

Fig. 2 Palinspastic resoration of the Corsica–Sardinia and Apulia margins at the end of Palaeogene.

Figure 3 shows all the published geochronological data available concerning the Tuscan province; new K/Ar age determinations on a peralkaline lamprophyre outcropping near Sisco (northeastern Corsica) are added here.

Velde[10] first defined the potassic peralkaline nature of the Sisco lamprophyres. The mineralogy is phlogopite, sanidine, olivine, quartz and an uncommon anphibole (potassic richterite). All the data strongly support the geochemical affinity of these rocks with those of the Tuscan province[11]. The dated samples were collected from the outcrop described and analysed by Velde[10] and belong to a sill intruded within the ophiolitic nappes (Schistes lustrés). Whole rock and separated phases were dated by the K/Ar method (Table 1). The errors (1σ) have been evaluated using the Cox and Dalrymple formula[12]. The K/Ar dates range from 14.3 to 15.4 Myr. In a plot of ^{40}Ar/^{36}Ar against ^{40}K/^{36}Ar they define an isochron of 14.2 ± 0.2 Myr with an initial ^{40}Ar/^{36}Ar value of 300.1 ± 0.6. This age is the oldest so far

Table 1 K–Ar ages of the Sisco peralkaline lamprophire*

Analysed phase	K (%)	^{40}Ar rad (%)	^{40}Ar rad ($\times 10^{-10}$ mol g^{-1})	^{40}Ar/^{36}Ar	^{40}K/^{36}Ar ($\times 10^3$)	Age (Myr)
Whole rock	7 15	57.6	1.82	696.3	481	14.3 (±0.4)
K-Feldspars	8.86	32.1	2.44	430.1	152	15 4 (±0.5)
Phologopite (60–100 mesh)	8.00	21.0	2.06	373.9	93.4	14.4 (±0.5)
	8.00	46.7	2.10	551.1	298	14 7 (±0.4)
Phlogopite (100–140 mesh)	8.11	21.1	2.23	372.9	87.3	15.3 (±0.5)
	8 11	27.9	2.13	409.0	132	14.7 (±0 5)

^{40}Ar was determined by isotope dilution mass spectrometry, using a GD-150 Varian Mat mass spectrometer and the ^{38}Ar-enriched Zurich spike. The calibration was checked by LP-6 USGS standard, a muscovite internal standard (MCT) and Bern LP-6 biotite. K was determined in duplicate by flame atomic absorption with a Perkin Elmer 303.

* $\lambda_\varepsilon = 0.585 \times 10^{-10}$ yr^{-1}; $\lambda_\beta = 4.72 \times 10^{-10}$ yr^{-1}; $^{40}K/K = 1.19 \times 10^{-4}$ atom/atom.

found in the north-Tyrrhenian post-Palaeogene magmatic province. Figure 4 shows these new data, and literature values, in an age against distance plot; the distances have been computed by projecting the magmatic centres on the Bastia–Radicofani line. The new data from North Corsica confirm the eastwards migration of the magmatism[4,6] giving 1.3 cm yr^{-1} as a mean migration velocity.

Contrasting models have been proposed to explain this age–space relationship. Alvarez[13] argued that the Tuscan magmatic activity belongs to a calc-alkaline sequence related to a former Benioff plane dipping eastwards under Italy. According to the Alvarez model the eastwards migration of the magmatism results from the subduction and simultaneous anticlockwise rotation of the Corsica–Sardinia microplate. Marinelli[11] postulated the existence of a hot spot under Tuscany ('Etruscan swell') and suggested that the eastwards migration of the magmatic activity is evidence of a movement of the Tuscan continental lithosphere towards the west with a velocity of about 1 cm yr^{-1}.

Our new model might explain better the genesis and the eastwards migration of the Tuscan magmatic activity, taking into account the main geodynamic events occurring in the Tyrrhenian area during Neogene and Pleistocene times.

The beginning of the Tuscan anatectic magmatism overlaps with the final phases of the Sardinian calc-alkaline volcanism[14]. This volcanism has been recently associated with the subduction of the continental Insubric–Apulian lithosphere dipping westwards beneath the Corsica–Sardinia block (Iberia plate)[15]. The Oligocene and Neogene Africa-verging nappes of the Apennines are interpreted, in this scheme, as peels detached from this subducing lithosphere and pushed toward the east and north-east[15] (Fig. 2).

Sialic material packed in the roots of the Apennine chain during the main compression phases might represent the source of the anatectic magmas. At that time, before the middle Miocene, the Tyrrhenian Sea had not yet developed as an extensional basin. Starting from middle–late Miocene times, tensional tectonics characterised the Tyrrhenian area, until an oceanic plain had developed by Messinian times[16,17]. The Tyrrhenian seafloor spreading is supposedly connected with an anticlockwise rotation of the Apennines[15]. According to this model, and assuming a rotation pole in the Tuscan area or further north, it is possible to reconcile the simultaneous continental magmatic activity in Tuscany with the tholeiitic activity on the Tyrrhenian abyssal plain during late Miocene and Pleistocene times.

The generation and ascent of the magma is probably a result of heat flow increase, pressure relief and fluid mobilisation during a period of tensional rift tectonics. The heat flow increase could be due to a hot spot[11] and/or a general rise of the isotherms in response to thinning of the lithosphere during rotation of the Italian peninsula. In any case, the considerable radioactive heat generation of the upper crustal material in the root zone should be taken into consideration. Furthermore isotopic and geochemical data reported for the Tuscan magmatic rocks support this model and suggest a mixing of upper crustal materials[2,18] with mantle derived magmas.

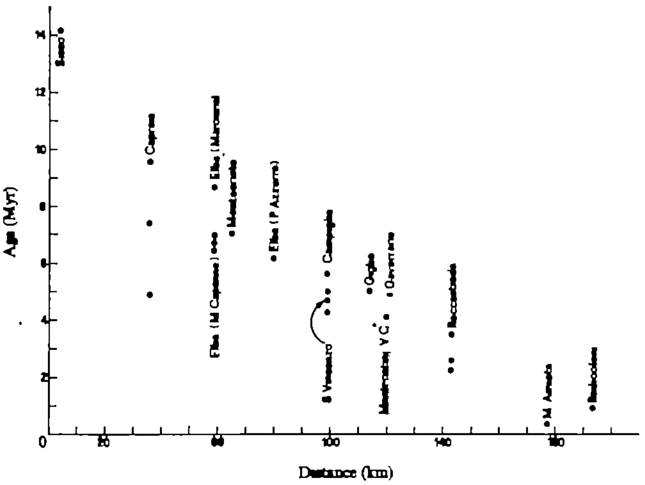

Fig. 4 Ages versus the distances of the magmatic episodes in the Tuscan province. The distances have been computed by projecting the magmatic centres on the Bastia–Radiocofani line.

The eastwards migration of the magmatism can be easily related to a progressive crustal thinning and subsequent rifting due to the anticlockwise rotation of the Apennines. The Tyrrhenian abyssal plain, being far from the rotation pole, is the area in which tensional tectonics are most apparent, so that thinning and rifting of the continental crust was followed by the generation of new oceanic crust in the south.

Finally, such a rotation model may explain the simultaneous late Miocene–Pliocene longitudinal rifting of the chain along the Tyrrhenian border and the nappe and fold development along the Adriatic front.

We thank Professor F. Innocenti and G. Marinelli for helpful discussion. This work was sponsored by the CNR, Geodynamic project, publ. N.132.

Do aerosol anomalies precede earthquakes?

REPORTS of strange animal behaviour in my home village, which was struck by the Friuli earthquake in northeastern Italy (6 May 1976) convinced me that aerosol particles were electrostatically charged before the quake and that the physiological effects were essentially caused by an increase of the ion concentration in the air resulting in reactions such as the serotonin irritation syndrome. A mechanism is suggested here for the liberation of electrical charge from underground: electrochemical glow discharge.

The most remarkable animal behaviour effects (the quake occurred at 2100 LT) were the following (a more detailed description is given elsewhere[1]). Deer formed flocks—in the late afternoon, a flock of 15 deer came down from the mountains and close to the village, crowding together with apparently no interest in grazing—an event never before seen in this area. Cats left the houses and the village—at the time of the quake no cat was apparently left in the village. They did not return until two days later (there were many aftershocks). In three cases, cats dragged kittens outdoors and bedded them in green vegetation. Before fleeing from an apartment a cat was seen to move its ears convulsively for some time. Mice and rats left their hiding places—on one farm mice and rats were observed running around before the quake. People were annoyed and surprised as all their five cats were missing. Fowl refused to roost a few hours before the quake. People fleeing from their houses during the quake found their fowl already scattered in the garden. The animals had apparently forced their way out from the pen before the disaster. On one farm, several minutes before the quake, the fowl made such a noise that farmers thought a fox had entered the chicken house. Cattle panicked in their barns—according to many reports, cattle showed clear signs of fear 15–20 minutes before the quake. The animals started to bellow, tear at their chains and paw their boxes. Dogs barked without apparent reason. This behaviour started 20 min before the quake. Some people were guarding their property, suspecting intruders, just before the quake hit. Birds emitted calls at unusual times—one person heard a cuckoo, never normally heard at night. Caged birds started to fly—in six places people observed that 10–15 min before the earthquake birds became restless and occasionally emitted calls. Then they began to beat their wings and finally started to fly. A bird kept its plumage wet—in the late afternoon before the quake occurred, one woman observed that her canary had emptied the water bowl which was filled daily and generally only half emptied in one day, she refilled it and shortly before the earthquake found it empty again; the bird must have kept wetting its plumage.

The characteristic animal behaviour observed in northeastern Italy by people with little experience of earthquakes (independent accounts from neighbouring areas are published elsewhere[2]) is essentially identical to that reported from China[3–7]. This can be seen from a publication by the Earthquake Office in Tientsin[8]. It advises that an earthquake may be imminent when cattle, sheep or horses refuse to get into the corral, when rats run out from their hiding place, when chickens fly up to the trees and pigs break out from their pens, when ducks refuse to go to the water and dogs bark for no obvious reason, when snakes come out from the winter hibernation, when pigeons are frightened and will not return to their nests, when rabbits with their ears erect jump up and crash into things and when fish jump out of the water as if frightened.

There are many other accounts of anomalous animal behaviour before earthquakes (see refs 9–21): 33 independent reports from all over the world were collected by the US Department of the Interior[18] and I have collected 78 reports with abundant supporting evidence from folk tradition and mythology[1]. After the successful prediction of the earthquake of Haicheng in China in 1975 the dramatic increase in the number of reports of anomalous animal behaviour was quoted as one of the principal reasons, as well as foreshock activity and water level changes, for the declaration of the state of emergency.

In the search for scientifically useful clues to the phenomenon I studied the case of a livestock train standing in a small town (Pontebba) awaiting customs clearance on the evening of the earthquake. The wagons were boxes of sheet iron with several rectangular openings only. The cattle and horses had been fed and watered. Under normal circumstances they stay quiet. Approximately 15–20 minutes before the earthquake, however, the animals started to show discomfort and produce excessive noise. The transportation workers decided to notify their superiors, fearing poisoning or disease. These wagons (Faraday cages) cannot apparently shield these pre-earthquake signals. Nor could small vibrations preceding the quake have been responsible for the unrest. There was only one, relatively strong, foreshock within one minute of the main quake and how could animals that have been travelling by train for days suddenly get panic-stricken? Why are birds that live in the trees frightened and how can such hypothetical small vibrations be distinguished from similar ones produced by trucks and trains?

The clue to this mysterious animal behaviour was finally found, in my opinion, when I spoke to a retired precision mechanic. As the time of the earthquake approached he was repairing a small wrist-watch. One operation consisted in placing a thin lamella of stainless steel—estimated to weigh a few tenths of a gram—on the clockwork. It would not stay there but jumped from its place. After several futile attempts the confused man went and looked at the weather outside; the sky was completely cloudless. After resuming his work he still found the strong electrostatic repulsion phenomenon; immediately afterwards the first shock occurred.

Only charged aerosol particles could have caused such a strong charging of metal parts in the same polarity. It led me to hypothesise that before the earthquake an unknown geophysical phenomenon liberates electrostatic charges from underground.

The Menlo Park Conference on abnormal animal behaviour before earthquakes[18] gave this hypothesis some additional weight by advancing arguments against several alternative potential geophysical signals of non-electric origin. Underground noise would not be heard better by most domestic animals, as the conduction of ultrasound signals to which they are more sensitive is drastically attenuated during its passage through rocks. Changes of the magnetic field of the Earth as well as possible barometric pressure changes would be smaller than those variations which most animals would usually experience and microshocks would also be detected by seismographs apart from being too frequent to cause serious discomfort to animals.

This hypothesis is supported by much circumstantial evidence[1] among which the following is the most convincing.

(1) There are many reports of physiological effects of charged aerosol particles on animals and humans[22]. Much work has been done on the action of small air ions (as the smallest charged aerosol particles are usually called), especially by A. P. Krüger *et al.*[23,24], who succeeded in tracing the biochemical factor responsible for the action of air ions on living beings. Experiments have shown that small positive ions increase the production of serotonin, a powerful neurohormone, engaged in physiological functions such as sleep, moods and the transmission of nervous

0028-0836/78/0276—0606$01.00

impulses. Subsequent investigations[25–28] supported these results and revealed that a typical kind of illness, felt during certain weather situations such as the Foehn in the Alps or the Sharav in the Near East, which are also characterised by abnormally high concentrations of positive ions, is also accompanied by a high serotonin production. The cluster of symptoms (migraine, nausea, vomiting, irritability, hyperperistaltis) was called the serotonin irritation syndrome. It can be successfully treated with negative ions or serotonin blocking agents.

(2) An electrostatic charging of aerosol particles can produce fog in air with less than 100% humidity[29]. Fogs or strange clouds have been explicitly designated as earthquake precursors since the days of Aristotle and Pliny, and there is a long record of such observations in Europe[10], America[1], and Japan[14] (chiki = the air from the ground). A detailed description of such a phenomenon is, for example, given by A. von Humboldt for an earthquake in Cumana, Venezuela[19].

(3) Light-producing electrical discharges are to be expected as a consequence of strong charging of aerosol particles. There are many reports of luminous phenomena during and before earthquakes.[9,14,19,20,30–33].

(4) The proposed electrical nature of the short-term earthquake precursory phenomenon makes it qualitatively comparable with transient electrical phenomena in the atmosphere preceding dramatic weather changes. Many characteristic features of reported animal behaviour are qualitatively similar before major storms[1]. It is possible that animals see in an earthquake a phantom storm. Their reactions might therefore partly be due to a weather instinct which is distorted by the unusual intensity in the development of the event and the physiological effect of air ions. This would explain the evolution of an 'earthquake sense' in animals in the absence of appropriate opportunities for natural selection.

(5) The atmospheric changes preceding strong earthquakes are apparently also felt by sensitive people. The term 'earthquake weather' is known in Europe, South America and in western US[1]. It is associated with an unusually warm and oppressive weather situation. The reported physiological reactions[9] are comparable to those felt during Foehn, Scirocco or Sharav, which are known to have been accompanied by high concentrations of positive air ions.

(6) There are old reports of qualitative measurements of the electricity of the air by means of electrometers during periods of aftershocks. One account is by A. von Humboldt[19] from Venezuela (1799) and one by V.-Eandi from Piemont[34,35] (1808). Both scientists report a marked increase of electricity during shocks. For both earthquake events there are parallel reports of anomalous animal behaviour. In certain descriptions of anomalous animal behaviour the electrostatic nature of the underlying phenomenon becomes directly evident. According to de Ballore[36], in Sicily it was said that an earthquake was imminent "when cats start crying, bristle their hair and sparks are released from their backs". Additional evidence is provided by the Chinese experience[6], that animals of very different temperament and sensitivity (58 species) are aware of approaching earthquakes. Remarkably, smaller animals (larger surface-to-volume ratio) are generally found to be more sensitive than bigger ones.

(7) The charged aerosol hypothesis does not only give an apparently consistent explanation of all important earthquake precursory phenomena from the popular tradition, which are occurring in the atmosphere, but is also consistent with an essential feature of the main earthquake theory of antiquity as elaborated by generations of Greek philosophers and especially by Aristotle. This claims that, before an earthquake, a strange gas (apparently warm and viscous) the 'pneuma' evolves from the Earth producing a series of atmospheric earthquake precursor phenomena (and the earthquake itself). The 'pneuma' of Greek philosophers could have been electricity of the air.

It is quantitatively justifiable to consider the piezoelectric effect in quartz-containing rocks (the average concentration of quartz in the Earth's surface is 15%) as the primary source of the electrostatic energy. There is reportedly sufficient alignment of piezoelectric microcrystals to produce macroscopic effects[37] and Finkelstein and Powell have estimated that many thousands of volts per metre could be generated by pressure waves of earthquakes (25–250 bar) (refs 38, 39). Attempts to explain earthquake lightning as a consequence of macroscopical electrical discharges through the air, however, failed to be convincing because of the measured low resistance of the ground (10^3 Ωm) compared with that of the air (10^9 Ωm). Electrical currents in the ground would rapidly neutralise separated charges.

These currents could, however, be the ultimate cause of charge liberation by inducing a phenomenon known as electrochemical glow discharge or glow discharge electrolysis[41,42]. The discharge is easily produced if the anode of an electrochemical cell is lifted slightly above the electrolyte's surface and the applied voltage simultaneously increased to maintain the electrical current across the gap. The resulting glow discharge can be maintained with a potential difference as low as 500 V and, if the gap is sufficiently thin even at atmospheric pressure (contact glow discharge[43]). Positive ions (mostly H_2O^+), accelerated towards the water surface will generate radicals and ions with yields comparable to that of α-particles. But attainable dose rates with mA-glow discharge currents can exceed that of conventional radiochemistry by a factor of 100–10,000 (ref. 42). Microscopic electrochemical glow discharges resulting from piezoelectric transient phenomena and the passage of electrical current across tiny fractures in rocks and thin water films also seem to provide a quantitatively satisfactory mechanism. Glow discharges in the range of 1 mA (telluric currents of this order of magnitude have been shown to occur in connection with earthquakes and volcanic eruptions[5,40]), with 3.7×10^{17} ions min^{-1} accelerated across 100 V towards a water surface could drastically change a typical ion concentration in the range of 10^4–10^6 cm^{-3} in the air above.

My consideration of many very old or inexact observations to support the proposed hypothesis does not meet present-day scientific standards and might provoke criticism. I believe this is unjustified as long as corresponding modern investigations do not exist. The question also arises as to whether our exclusive reliance on instrumental research (with the exception of China) and renunciation of a vast treasure of observations by scientifically unqualified people is justifiable in the case of earthquakes. In support of this view a remarkable fact should be mentioned: 1,900 yr ago the Roman naturalist and writer Pliny the Elder specified four different signals, which could indicate a threatening earthquake[44]. Three of these, the appearance of foreshocks, turbidity in water wells and frightened birds, are considered relevant today, as they were used to forecast the earthquake of Haicheng in China[3,5]. The fourth, the appearance of an atmospheric sign, a special kind of fog in an otherwise clear sky, could prove to be relevant if the hypothesis proposed in this paper were confirmed. Do we know more about short-term earthquake prediction than did the Romans?

This work was private research and not part of the program of the institute.

Evidence for domestication of the dog 12,000 years ago in the Natufian of Israel

THREE canid finds from the Natufian in the northern Israeli sites of Ein Mallaha (Eynan) and Hayonim terrace indicate a special man–animal relationship. These consist of a diminutive carnassial and mandible, and a wolf or dog puppy skeleton buried with a human. The finding of a puppy skeleton in such close association with man is of particular significance as an indication of a close relationship between man and dog.

A domestic animal is one whose breeding is largely controlled by man. Evolution of a domesticated species, therefore, results mainly from artificial selection, with natural selection playing a subsidiary part. The process of domestication implies the separating off of a breeding stock from its wild forebears. Most workers agree that the wild progenitor of the dog was the wolf *Canis lupus*[1–5].

A *Canis* skull from the Mesolithic site of Star Carr, England (9,538 ± 350 BP) was identified as a dog, on the basis of dental overlap[2]. Lawrence[3] identified dog from Idaho (USA, 10,400 BP) and from eastern Anatolia (~9,000 BP). More recently, Turnbull and Reed[6] suggested that a mandible from the Zarzian (~12,000 BP) of Palegawra cave (Zagros mountains, Iraq) belonged to a dog, on the basis of dental overlap and small size.

The finds we report here come from the Natufian, an Epipalaeolithic culture (formerly referred to as a Mesolithic culture) and dates to 12,000–10,000 yr ago. The Natufians, whose culture was limited to the Levant, are considered to have been hunter-gatherers, and were the first peoples to live in circular dwellings in what were perhaps the earliest permanently settled villages. Their sites, compared with those of preceding periods are larger, occupying areas of 1,000 to 3,000 m^2, and contain numerous pounding stones (pestles and mortars) as well as, for the first time, large cemeteries. Art forms are also found, as is a highly sophisticated tool kit, consisting largely of microliths, including lunates. They were the antecedants of the first agriculturalists in the region.

Bate's claim[7] for the domestic status of a *Canis* skull from the Natufianof El Wad cave (Mount Carmel, Israel) could not be confirmed[8]. Recent excavations at two Natufian sites in northern Israel, Mallaha (Eynan) and Hayonim terrace, provide what we believe to be more concrete evidence for some kind of special relationship, perhaps domestication, between man and dog/wolf in this early period, around 12,000 BP.

The site of Mallaha, near the old Huleh lake in the upper Jordan valley, has been under excavation since 1955 (ref. 9). Two phases of Natufian occupation have been distinguished[10]: the canid osteological remains, a mandible from a living floor and a puppy from a tomb, both come from the lower one. This has so far revealed three superposed half-buried dwellings, originally probably circular and 9–11 m in diameter, whose northern halves are missing. The walls, some preserved to a height of more than 1 m, were built of limestone blocks, piled more or less vertically. The flint industry is characterised by lunates rarely less than 1.5 cm in length, most of which bear 'Helwan retouch', indicating an Early Natufian assemblage. Basalt pestles and mortars are fairly frequent, as are bone points, needles, pendants and some bone sickle handles.

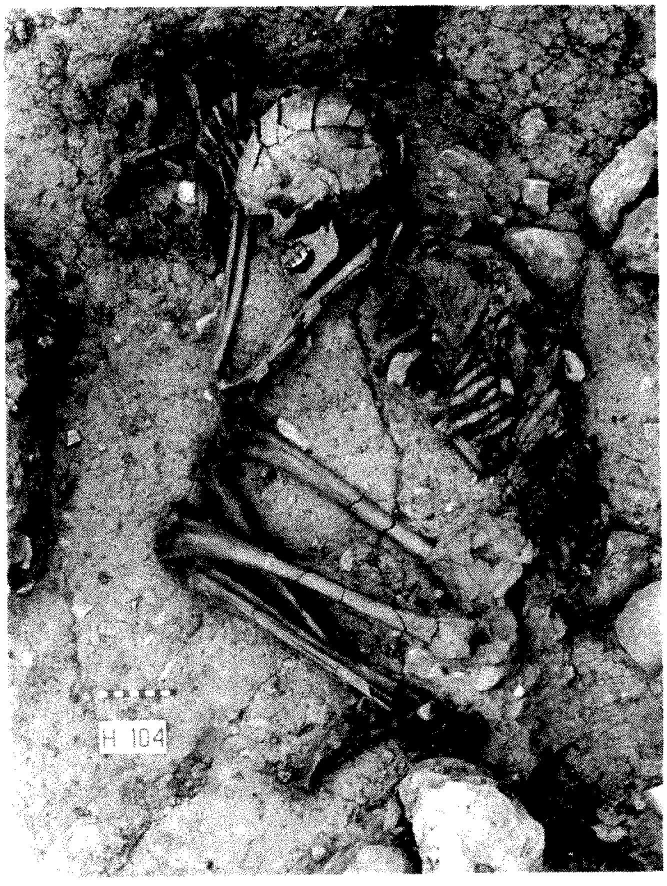

Fig. 1 Tomb H. 104 at Mallaha, showing the human skeleton and puppy.

In the entrance to dwelling 131, the oldest so far excavated in Mallaha, a large slab of limestone was found on the floor. This has been interpreted to indicate the presence of a burial (H. 104, ref. 11) especially due to its proximity to a human skeleton which lay 25 cm below it. The human skeleton, whose sex cannot be determined because of the damage of the pelvis, lay flexed on its right side, and judging by the state of its dentition, was an old individual. Its left wrist was partially under its forehead, and hand upon the thorax of a puppy, which has evidently been buried complete with the human (Fig. 1). All the milk teeth of the puppy are fully erupted, and of the long bones exposed, a humerus has both epiphyses open, indicating that the age at

0028-0836/78/0276—0608$01.00

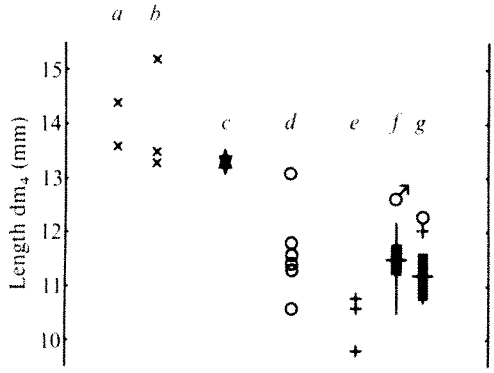

Fig. 2 Maximum length (mm) of the last lower milk molar (dm$_4$, milk carnassial) of canid puppies. *a*, Two wolves from Turkey; *b*, three wolves from Israel; *c*, the Mallaha puppy; *d*, six dogs from Turkey, Israel and Egypt; *e*, three jackals from Turkey; *f*, 14 male jackals from Israel, range, mean ±95% confidence limits; *g*, six female jackals from Israel, range, mean ±95% confidence limits. (Data from Turkey supplied by S. Payne).

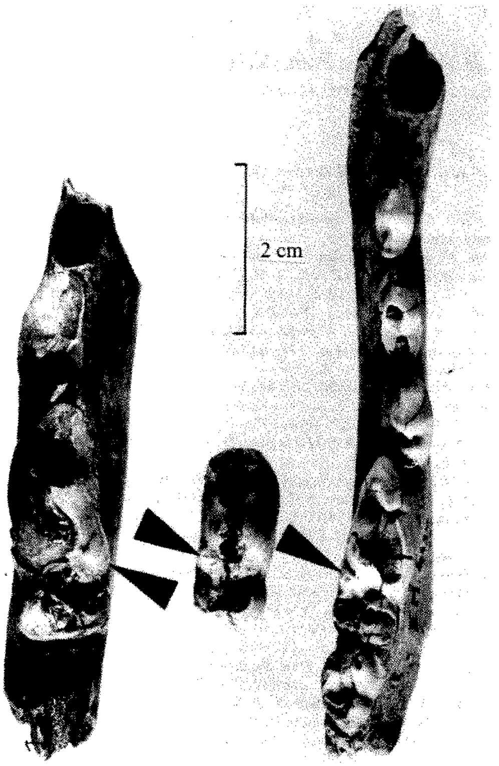
death was between 3–5 months[12], while the advanced state of wear of the lower milk carnassial makes an age of 4–5 months more likely. The upper teeth are too damaged to be measured, but the dm$_4$ which is intact, has a maximum crown length of 13.3 mm. Comparison with the same tooth of recent Israeli and Turkish wolves, jackals and dogs (Fig. 2) indicates that the fossil puppy was either a dog or a wolf, but not a jackal, being outside the size range of the latter.

An adult canid mandible was found in dwelling 131. It came from an undisturbed living floor, characterised by seven post holes, and lay not far from two hearths containing bones which included a human cranium and a pair of gazelle horn cores. The mandible is complete from canine to second molar and belongs to a large canid. The metaconid on the M$_1$ is poorly developed (Fig. 3) as in wolf and dog; unlike the jackal metaconid which protrudes lingually and is more prominent[1,13].

Fig. 3 Occlusal views of the Hayonim terrace carnassial (centre) and Mallaha mandible (right) compared with an Upper Pleistocene wolf mandible fragment (P$_4$ and M$_1$) from Ein Gev IV (Jordan valley, Geometric Kebaran A period). The M$_1$ metaconids are arrowed.



Osteological separation of the dog and wolf is problematical, but tooth crowding and smaller size have been used as criteria for the identification of dogs. It has frequently been claimed that dog jaws are slightly shorter than those of their wolf progenitors, resulting in a certain degree of dental overlap, particularly of the lower fourth premolar and the lower first molar[2,3,6]. This dental overlap was analysed using an index of overlap (crown length of M$_1$ ÷ alveolar length from P$_4$ to M$_1$). The value for the Mallaha mandible is 0.67, indicating some degree of overlap (Fig. 3). A collection of nine recent dogs from Israel and Egypt, however, gave values from 0.65 to 0.70 (mean 0.68) and a collection of 34 recent wolves from Israel gave values from 0.62 to 0.67 (mean 0.65), with six specimens actually possessing values of 0.67. Another index, the length M$_1$ ÷ alveolar length of the lower premolars, showed a similar overlap between dogs and wolves. These indicate that dental overlap criteria are not very efficacious in dog–wolf separation, and are probably to some extent dependent.

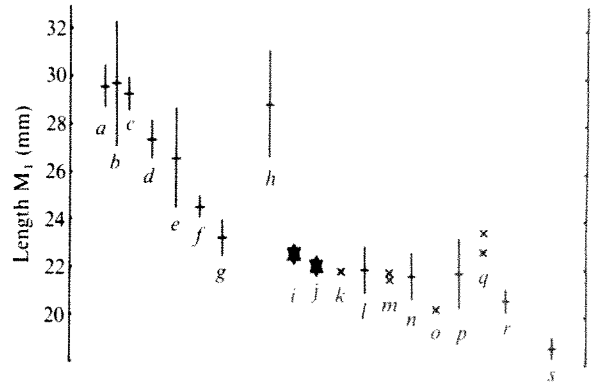


Fig. 4 Antero-posterior length of M$_1$ of recent and fossil canids. These show the north–south size cline in recent palaearctic wolves (*a* to *g*); the Pleistocene–Holocene diminution in the Levant (*h* versus *f*) and the wolf–dog differential (*f* versus *i* to *r*). Samples are represented by their mean ±95% confidence limits, single specimens by a star or cross. Recent wolves: *a*, Greenland and Ellesmere land, $n = 12$ (ref. 20); *b*, Russia and north Scandinavia, $n = 4$; *c*, Denmark, Holocene and recent, $n = 7$ (ref. 20); *d*, Turkey, $n = 9$; *e*, Zagros mountains, $n = 5$ (ref. 6); *f*, Israel, $n = 26$; *g*, Arabian peninsula, $n = 7$. Fossil wolves and dogs *h*, Ksar Akil U. Pleistocene, $n = 4$ (ref.21); Tabun B, $n = 1$ (ref. 7); and Ein Gev IV, $n = 1$ combined; *i*, Mallaha mandible M$_1$; *j*, Hayonim terrace M$_1$; *k*, Palegawra *Canis* (ref. 6); *l*, Jericho Pre-Pottery Neolithic to Early and Mid Bronze Ages, $n = 7$ (Ref. 17); *m*, Cayonu, east Anatolia, 9,000 BP (ref. 3); *n*, Korucutepe, east Anatolia, Bronze Age, $n = 12$ (ref. 22); *o*, Arad, north Negev, Early Bronze Age; *p*, Persian period of Israel, $n = 6$; *q*, two male dogs from Suez, Egypt; *r*, dogs from archaeological sites in Hungary, $n = 42$ (ref. 23). Recent jackals: *s*, Israel $n = 24$.

The terrace of Hayonim, in the western Galilee, was excavated by O. Bar Yosef in 1966 and 1969, and by D. Henry in 1974–75 (ref. 14). Over a thin layer assigned typologically to the Geometric Kebaran A, lies a Natufian assemblage. From the lowermost level of this a single ^{14}C date of 11,920 BP (SMU 231) is available. The canid tooth reported here is a lower carnassial from the trial trench (square D depth 30–50 cm, 1974 season's excavation) and is located within the Natufian. Its crown is chipped at the anterior end, and like the M$_1$ of the Mallaha mandible described above, is morphologically wolf-dog, with a poorly developed metaconid (Fig. 3).

The sizes of the M$_1$'s of both these finds are compared with other wolves and dogs both geographically with recent wolves from the Palaearctic region, and temporally with Near Eastern Upper Pleistocene to recent wolves and dogs (Fig. 4 and Table 1). The results of this analysis indicate firstly that recent wolves increase in size with increasing latitude in accordance with Bergmann's rule, and secondly that Upper Pleistocene wolves from the Levant were larger than recent ones, so that the wolf, like the mole rat, gazelle, goat, cat, fox, hyaena, wild boar and

aurochs decreased in size at about the end of the Pleistocene[15–18]. Dogs from later archaeological sites in the Near East are even smaller than recent wolves. Thus three size classes of the wolf–dog line exist in Israel—Upper Pleistocene wolves, recent wolves and domestic dogs. The problem, therefore, is to which of the latter two size classes the Mallaha and Hayonim finds belong. Combining the two M_1 measurements, and comparing them with modern Israeli wolves, the probability that they belong to the latter is <0.01 (Student's *t* test) and we conclude that on this basis they are dog rather than small wolves.

Having distinguished three size classes for the Israeli Upper Pleistocene–Holocene wolf-dog line, we postulate two independent factors as having been responsible for each of the two size declines: (1) the temperature elevation at the end of the Pleistocene, which we associate with the difference between Upper Pleistocene and recent wolves, and (2) domestication resulting in the difference between recent wolves and dogs.

These finds are important in that they support evidence from other arachaeological sites for interaction between man and canids in the Epipalaeolithic. The puppy, unique among Natufian burials, offers proof that an affectionate rather than gastronomic relationship existed between it and the buried person, an addition to our knowledge of the way of life of Natufian hunter-gatherers. The contemporary diminutive adult carnassials, of size equivalent to dog and not wolf, indicate that *Canis lupus* had, by the early Natufian, been subject to some degree of selective breeding by man. It would seem unlikely that taming alone would be sufficient to bring about this kind of change in the animals' dentition. We suggest, therefore, that domestication of the wolf occurred 12,000 years ago, before that of the food animals such as goat, sheep, cattle and pig, which were probably not domesticated until one or more millenia later[19]. If this hypothesis is correct, then together with Starr Carr in England, and Palegawra in Iraq, we might conclude that it was 'man-the-hunter' who first domesticated the wolf, another social carnivore.

We thank O. Bar Yosef, J. Bouchud, C. Grigson, J. Heller, J. Perrot, C. Reed and E. Tchernov for critically reading the manuscript, A. Dagand for arranging transport of tomb H. 104 to the Amnon Assaf Museum of Prehistory, Kibbutz Ma'ayan Baruch, and A. Dagand and A. Niv for photography.

Note added in proof: The following dates pertaining to the puppy burial level at Mallah have been received from the University of Lyons radiocarbon laboratory: Ly 1660 11,590±540 BP; Ly 1661 11,740±570 BP; Ly 1662 11,310±880 BP.

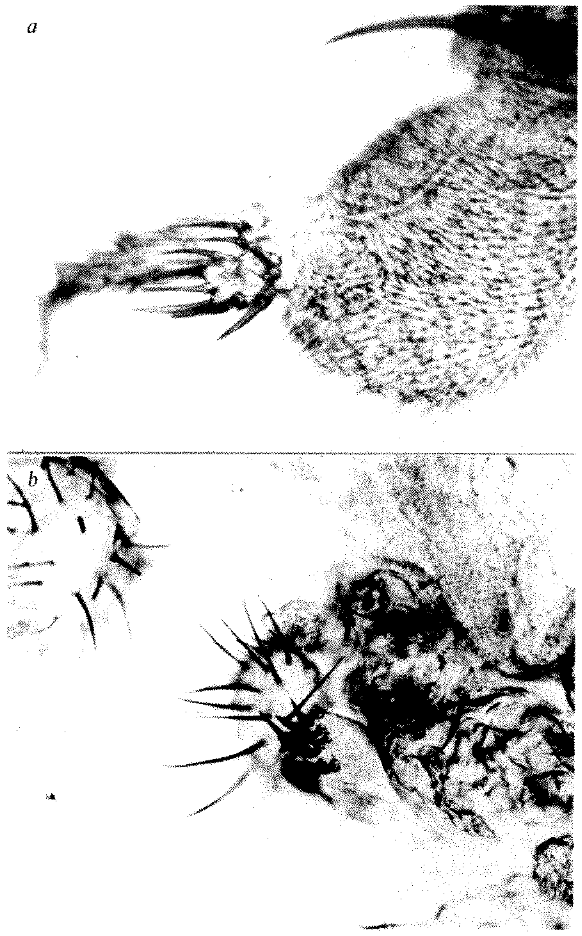
Tumorous head is a maternal-effect homoeotic mutant of *Drosophila melanogaster*

THE homoeotic mutants of *Drosophila* are of special interest in developmental biology because they cause the substitution of one body segment by another in the adult. The antennae of *tumorous head* (*tuh*) flies are replaced by mesothoracic leg tissue and part of the head by genital structures[1,2] (Fig. 1). Homoeotic mutants are thought to be the result of mutations in regulatory genes[3] which cause a suppression of the activity of one set of genes and the activation of an alternative set to bring about such a specific, well-defined transformation. These mutations somehow cause a group of cells at some stage in the life cycle to change their developmental pathway and differentiate during metamorphosis into different structures from those which they would normally form. We have analysed the *tumorous head* mutant and report here that it is probably the consequence of a gene acting at the time of determination.

Homoeotic genes act at one of several possible stages in development to bring about the observed phenotypic changes[3]. They could alter the initial determination of the cells, so that early in development, around blastoderm formation, when cells are becoming committed to follow specific pathways in development they become leg and genitalia instead of antenna and head. Many homoeotic genes need to be active throughout development[4,5], so that when determined cells divide the daughter cells also have the same developmental commitment. Thus, homoeotic genes could be envisaged which alter the maintenance of determination, in this case the cells would initially be determined correctly but because of the mutant gene products are unstable and change determination during development. Other genes could act at the time of differentiation by incorrect interpretation of the state of determination. *Bithorax* (*bx*) which transforms the haltere to wing is needed throughout development and probably affects the maintenance of determination[4,5]. *Contrabithorax* (*Cbx*)[6] which transforms the wing to haltere acts late in development and is also probably affecting the stability of cell determination.

Fig. 1 *a*, Third antennal segment transformed to leg; *b*, rostral-haut transformed to genitalia.



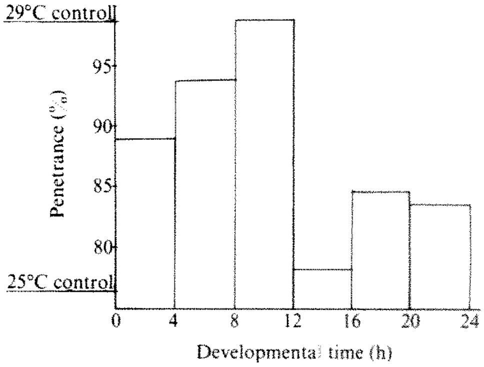


Fig. 2 Temperature sensitive period during embryogenesis of *tuh-3*. To establish a t.s.p. embryos laid by *tuh-3* mothers were shifted to 29 °C for 4-h pulses. Embryogenesis in *Drosophila melanogaster* takes 24 h to complete, thus the following pulses were applied: 0–4, 4–8, 8–12, 12–16, 16–20 and 20–24 h after oviposition. Temperature shifts later in development indicated that there is no temperature sensitivity for post-embryonic stages. Between 100 and 400 adults were examined for each pulse applied and a similar response was obtained in 3 independent repeats of the experiment.

The first few hours of embryogenesis in *Drosophila* are under the control of components laid in the egg by the mother [7–9] and hence depend directly on maternal gene activity. Cells develop according to their location in the embryo[10,11]. One could therefore expect that a gene affecting the initial determination of the cells would act during early embryogenesis or during oogenesis. A mutant in this class may well be a maternal effect mutation.

Table 1 *Tumorous head* is a maternal-effect homoeotic mutant

Female parent	Male parent	Number of flies scored	Penetrance (%)
tuh-3/*tuh-3*	wild type	323	18
wild type	*tuh-3*/*tuh-3*	465	0
tuh-3/*tuh-3*	*tuh-3*/*tuh-3*	714	53

Our experiments with *tumorous head* suggest that it is an unusual homoeotic mutation which fulfils the requirements of a mutant having its effect at the time of determination. There has been considerable genetic analysis of *tumorous head*, especially concerning the role of modifiers, enhancers and chromosome rearrangements[12,13]. We took the original *tuh-1a*; *tuh-3* stock which contained some flies with tumorous head phenotype under the control of a third chromosome mutation (*tuh-3*) and a modifier on the first chromosome (*tuh-1a*). We isolated *tuh-3* from this stock and established a line free of known enhancers. Our homozygous *tuh-3* stock had a penetrance (percentage of flies showing tumorous head phenotype) of 70% in contrast to those of previous workers[3] where the penetrance was 3%.

The *tuh-3* stock behaved as a maternal-effect homoeotic mutant. When homozygous *tuh-3* females were crossed to wild-type males some of the progeny showed the tumorous head phenotype but the reciprocal cross of *tuh-3* males to wild-type females gives no tumorous head phenotype. The gene also seemed to be active in early embryogenesis as *tuh-3* females

0028-0836/78/0276—0611$01.00

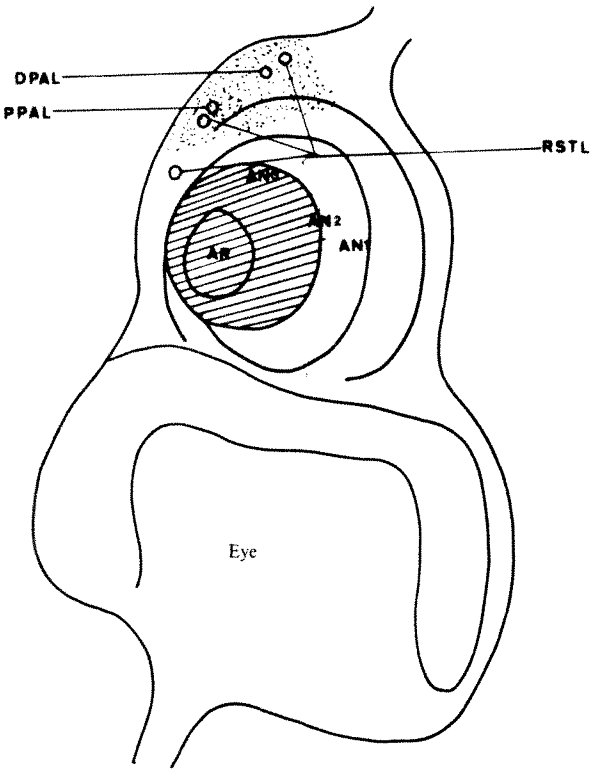

Fig. 3 Eye-antennal fate map indicating regions which give rise to the genitalia and leg transformations. Various regions of the disk were cut and implanted into host larvae where they metamorphosed with their host. Implants were scored for homoeotic transformations. In 33% of implants recovered from fragments containing the arista and third antennal segment we found leg tissue present and in 33% of implants recovered from fragments containing the rostralhaut region we found genitalia tissue present. RSTL, rostralhaut; AN1, AN2, AN3, 1st, 2nd and 3rd antennal segments respectively; DPAL, distal palpus bristles; AR, arista; PPAL, proximal palpus bristles. Stippled area, region that transforms to genitalia; hatched area, region that transforms to leg.

crossed to *tuh-3* males give more tumorous head progeny than when they are crossed to wild-type males (Table 1).

The temperative sensitive period (t.s.p.) of mutants is thought to be indicative of the time at which the gene products are being activated, thus the gene must be active before t.s.p. (refs 14,15). *Tumorous head* is temperature sensitive during embryogenesis and the pulse giving the highest *tumorous head* penetrance is 8–12 h after oviposition (Fig. 2). This then would agree with the *tuh-3*$^+$ gene being involved in determination.

Interestingly *tumorous head* transforms cells in the eye-antenna imaginal disk into cells from two different disks located in different body segments[16], the second leg disk in the mesothoracic segment and the genital disk in the last abdominal segment. All other known viable homoeotics act by altering cells from one disk to one other segment only[15,17] (for example, *bithorax* transforms metathoracic disk cells into mesothoracic disk cells[4]) or to another compartment of the same structure (for example, *engrailed* transforms posterior wing cells into anterior wing cells[18]). The mutant *proboscipedia* transforms the proboscis to antenna or leg, but not simultaneously to both structures in one fly; and two lethal mutants have been described which transform from genitalia to leg and antenna[19].

We have cut up the eye-antenna disks of *tumorous head* larvae (one can detect those with outgrowths in late third instar disks) and forced them through metamorphosis in a larval host[20]. In this way we have mapped the area of the disk involved in the homoeotic transformation (Fig. 3). The two regions involved are in extremely close proximity in the eye-antenna disk, although not necessarily in the embryo[21], but they undergo homoeotic transformations to very different segments of the fly.

As *tumorous head* is maternally controlled and has its t.s.p. early in embryogenesis, we would like to suggest that it is a candidate for a homoeotic gene acting at the level of embryonic determination.

Genetic variability and population structure of *Poecilia latipinna*

THE pattern of genetic variability among natural populations is commonly attributed to the influence of environmental heterogeneity on natural selection[1,2]. However, I report here that in *Poecilia latipinna* (Pisces: Poeciliidae), a small ovoviviparous fish, genetic variability is more closely related to local population structure, in particular, the adult sex ratio.

P. latipinna inhabits the brackish water lowlands along the Atlantic and Gulf coasts of the US and Mexico. Fourteen population samples were collected by hand seine in the northernmost two-thirds of the species range between South Carolina and Texas. For each population, the numbers of each sex were counted, and phenotypic males were assigned to one of four classes based on the development of primary and secondary sexual characters. These classes were: (1) immature male—anal fin only partially transformed into a gonopodium (male copulatory organ); (2) mature male—gonopodium completely formed, but no secondary sexual characters acquired; (3) transformed male—mature individuals possessing one or more secondary sexual characters: elongation of second ray of pelvic fins, and anterior displacement of pelvic girdle; (4) dominant male—fully developed complement of secondary sexual characters, including a large, sail-like dorsal fin (fin rays at least long enough to reach the base of the caudal fin). Both field and laboratory observations have shown that the sailfin character has a significant role as an indicator of social status during sexual and agonistic encounters[3,4].

The presumptive genotypes of all individuals in each population were determined by starch-gel electrophoresis of 21 cellular enzymes and two nonspecific muscle proteins. Seventeen allozyme loci were polymorphic in at least one population (frequency of most common allele was 0.99). On average, 43%

0028-0836/78/0276—0612$01.00

of the loci were polymorphic in each population. Within populations, the genetic variability (expressed as $\bar{H}$, the mean proportion of heterozygous loci per individual) was 3.6–10%, which is comparable to similar measures in other fishes[5].

The extensive geographical range of *P. latipinna*, encompassing a diversity of temperate to tropical climates, offers an excellent opportunity to investigate the influence of environmental heterogeneity on genetic variability. However, the pattern of population-level genetic variability does not seem to be a simple function of any discernible environmental gradient. The regression of $\bar{H}$ against 13 climatic variables (water temperature—mean high, low and range; water density—mean high, low and range; rainfall; pan evaporation; heating degree days, 18 °C baseline; solar radiation; length of breeding season—water temperature >20 °C (ref. 6); number of days with temperature above 32 °C or below 0 °C)[7,8], both singly and in combination, did not show any statistically significant relationships. On the contrary, inspection of the geographical distribution of genetic variability (Fig. 1) shows that low levels of $\bar{H}$ can occur in both equable (KW) and rigorous (MB) extremes of the species range. Similarly, both highly seasonal (MB, MC, RV) and highly stable (KW) environments display reduced genetic variability. The San Marcos population (SM), which shows the highest level of genetic variability in the species ($\bar{H} = 10.0$), occupies a remarkably stable hot-springs habitat (annual temperature range 22–22.5 °C)[9,10]. In light of such contradictory results, one might reasonably conclude that genetic variability in *P. latipinna* is responding to some unrecognised factor which is not an obvious component of local environmental heterogeneity.

The measure which successfully reflects interpopulation changes in $\bar{H}$ is the sex ratio of breeding individuals, which in this study is calculated as the number of females per dominant, or sailfin, male (Fig. 2; Kendall's rank correlation = −0.65, $0.001 < P < 0.01$). In *P. latipinna* populations, the number of dominant males, both past and present, can be reliably determined because the sailfin character is a permanent morphological change. In other poeciliid species which form male dominance hierarchies, the accessory display signal possessed by high ranking males is usually some form of distinctive coloration[11–19], which may diminish, or even disappear, with the loss of social status[13–19]. The number of dominant males in a population is of interest because many investigators have proposed that social dominance reinforces male reproductive success, even to the extent that dominant males may nearly monopolise the insemination of females[13–19]. If this concept of dominance and its role in the regulation of mating activity is applied to *P. latipinna*, then the explanation for the relationship between sex ratio and $\bar{H}$ is straightforward: as the proportion of dominant males in a population decreases, the paternal genetic contribution becomes channelled through fewer individuals. Thus, for any constant population size (N), as the sex ratio of breeding individuals becomes more skewed, the local effective population size (N_e) declines[20], and consequently genetic variability is reduced[21–23]. Previously, population size reduction[24,25] and reproductive behaviour[26–28] have been used to explain low levels of genetic variability in other organisms, but in *P. latipinna* the ratio of females to dominant males combines both of these concepts in a single direct measure of population structure.

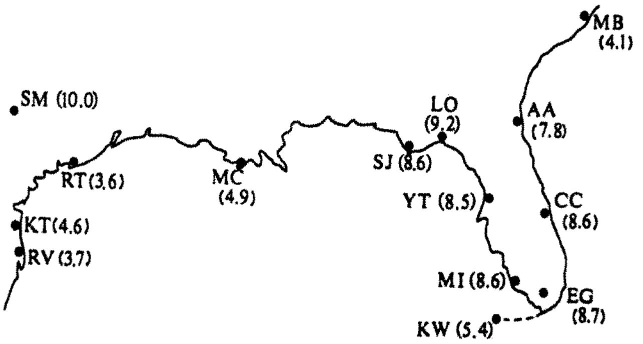

Fig. 1 The geographical location and the value of mean heterozygosity, $\bar{H}$, for 14 populations of *P. latipinna* from the Atlantic and Gulf coasts. Collection sites and sample sizes are as follows: South Carolina: Myrtle Beach (MB, 46); Florida: Jacksonville (AA, 53), Cape Canaveral (CC, 63), Key West (KW, 96), Everglades (EG, 25), Marco Island (MI, 50), Yankeetown (YT, 64), Live Oak Island (LO, 81), Port St Joe (SJ, 16); Louisiana: Morgan City (MC, 36); Texas: San Marcos (SM, 128), Rockport (RT, 61), Kingsville (KT, 73), Brownsville (RV, 256). Electrophoresis and enzyme assays performed on crude tissue extracts produced the following enzymes: eye esterase, lactate dehydrogenase (LDH); liver esterase, LDH, isocitrate dehydrogenase (IDH), phospho-gluco-isomerase (PGI), indophenol oxidase (IPO), peptidase (glycyl-tyrosine); muscle esterase, LDH, malate dehydrogenase (MDH), IDH, PGI, phospho-glucomutase (PGM), α-glycerophosphate dehydrogenase, creatine kinase, aldolase, peptidase (glycylglycine), nonspecific muscle protein. See ref. 4 for details of techniques.

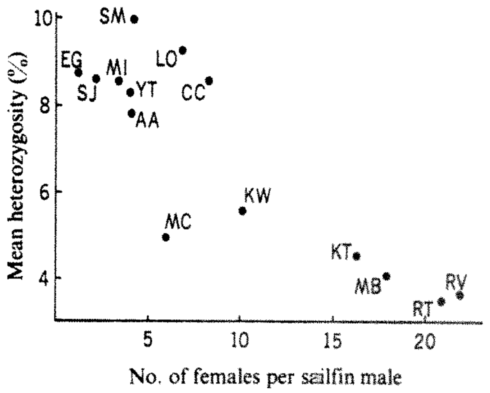

Fig. 2 Mean heterozygosity, $\bar{H}$, is inversely proportional to the ratio of females to dominant (sailfin) males.

It is possible that the observed sex ratios are not reflections of the true population structure, but are merely the artefacts of sampling technique or differential habitat selection by the sexes (or social classes). In this study such effects are minimal because the shallow streams and ponds where *P. latipinna* is found are usually small enough to obtain thorough samples. Even if one accepts the observed sex ratio as an accurate representation of local population structure, it could still be argued that the range of genetic variability in these samples is primarily determined by differences in gross population size. Without a careful census or identification of reproductive units this proposition is difficult to contest. However, rough estimates of gross population size at each sample locality can be obtained by taking the product of population density and habitat area. Such calculations show that to a first approximation the expectations for the effect of gross population size on $\bar{H}$ are not fulfilled: the two largest populations sampled in this study (KW and RV) fall at the low end of the range of heterozygosity; likewise, the two smallest populations (EG and SJ) are among the most genetically diverse. Reproductive substructuring within large, continuous populations could account for some instances of low genetic variability[29,30], but it is improbable that these objectively smaller populations (EG and SJ) are part of a larger (but undetected) panmictic unit. Another alternative would be that $\bar{H}$ is a function of the number of individuals in each sample, but no correlation was found between these two factors ($r = 0.19$; $P > 0.50$).

The appearance of a close association between population structure and genetic variability suggests that the interactions which regulate the local abundance of dominant males may be important adaptive features of poeciliid population biology. However, sources of variation in population structure need not be limited to intraspecific mechanisms. For example, studies of other poeciliids have shown that predatory fishes can significantly alter male demography by selectively feeding on the larger, showier males[11,16,31]. As no large, potential predators were found to be sympatric with *P. latipinna* in these collections, the observed sex ratios are probably not greatly affected by this type of interaction.

In *P. latipinna* mean heterozygosity varies not with the degree of environmental heterogeneity, but with the proportion of dominant males in a population. This relationship is most easily explained in terms of differences in local effective population size brought about by the hierarchical regulation of male mating activity.

I thank J. Germano, R. G. Harrison, H. A. Lessios and R. C. Vrijenhoek for suggestions. Research was supported by the Society of Sigma Xi and NSF grant GB50405 to D.E.S.

Arginine vasopressin maintains ethanol tolerance

THE neurohypophyseal hormone, [Arg⁸]vasopressin (AVP), like some of its analogues and smaller peptides of related structure, has the capacity to influence memory-related processes through direct action in the central nervous system[1–4]. These peptides have relatively long-lasting effects on memory consolidation or on retrieval of information[1,5]. It has been suggested that development of functional tolerance to drug effects involves an adaptive mechanism in the CNS similar to that which occurs during learning and/or memory consolidation[6,7]. We therefore wished to extend our studies[4] of the central actions of the neurohypophyseal hormones to include an investigation of the influence of these peptides on various aspects of functional tolerance to ethanol. One of the most consistently demonstrable effects of the neurohypophyseal peptides with respect to memory is the ability to inhibit the extinction of a conditioned avoidance response[1–3,5]. We now present evidence that treatment of animals with AVP during and after chronic ethanol administration leads to long-term maintenance of tolerance to the hypothermic and sedative effects of ethanol.

Male C57BL/6 mice were fed a liquid diet containing 7% (v/v) ethanol or an equicaloric amount of sucrose (controls) for 7 days[8]. On the morning of the eighth day, all mice were offered the sucrose-containing liquid diet (withdrawal). Using this regimen, we have previously shown that tolerance to the hypothermic and sedative effects of ethanol and signs of physical dependence were evident after withdrawal of ethanol from the animals' diet[8]. In the present experiments, animals received daily subcutaneous (s.c.) injections of 10 μg of AVP or oxytocin in 0.1 ml saline, or saline alone, throughout the drinking period and for 9 days after withdrawal. Animals were not injected with peptides on the day on which the ethanol-containing diets were removed, since the animals undergoing withdrawal were subject to handling-induced seizures. Four groups of animals were included in each experiment. The first group consumed the sucrose-containing diet and received saline injections. The second group consumed the sucrose-containing diet and received hormone injections. The animals consuming the ethanol-containing diet were similarly divided into a group receiving saline injections and a group receiving hormone injections. During the drinking period, ethanol consumption, intoxication and blood alcohol levels[8,9] were monitored daily. After removal of the ethanol-containing diet, withdrawal hypothermia and behavioural hyperexcitability[8] were observed at 2-h intervals for 12 h and blood alcohol levels were determined at 2-h intervals for 6 h in certain animals[9]. Tolerance to ethanol, determined by the hypothermic response and duration of loss of righting reflex after an intraperitoneal (i.p.) injection of 3 g per kg ethanol[7] was evaluated 24 h after withdrawal, and at 3-day intervals (starting on the third day after withdrawal) for 18 days thereafter. During tolerance testing ethanol metabolism was monitored in randomly selected mice from each group.

Blood alcohol levels during the drinking period and the clearance of alcohol after withdrawal and during tolerance testing were similar in all animals receiving the ethanol-containing diet. Signs of physical dependence, evident in the mice after ethanol withdrawal, also seemed to be similar in animals given saline, AVP or oxytocin[10].

Functional tolerance was first determined at a time when overt withdrawal signs had subsided (24 h after withdrawal). Figure 1 shows the time course for disappearance of tolerance after animals were withdrawn from the ethanol-containing diet. At 24 h and 3 days after withdrawal, the response to the challenge dose (3 g per kg) of ethanol was significantly less, both in terms of hypothermia (Fig. 1*a*) and 'sleep time' (Fig. 1*b*), in all groups of animals which had consumed the ethanol-containing diets as compared to their respective controls. The response of control animals which had received AVP treatment was not significantly different from that of control animals which had received saline at any time tested (Fig. 1); the same was true for control animals which had received oxytocin (data not shown).

At 6 days after withdrawal of ethanol, animals injected with saline were no longer tolerant to the sedative or hypothermic actions of ethanol (Fig. 1 and see ref. 8); that is, their responses were not significantly different from controls. Ethanol-consuming animals which had been treated with oxytocin also were no longer tolerant. In contrast, at 6 days after ethanol withdrawal, animals which had received AVP remained significantly tolerant to the effects of ethanol, as measured by both change in body temperature and sleep time in response to the challenge ethanol dose. This tolerance persisted during the time that the animals were treated with AVP (Fig. 1), and when AVP treatment was discontinued, at 9 days after withdrawal, ethanol tolerance disappeared with a time course similar to that seen in the saline and oxytocin treatment groups. Thus, at 3 days after the end of AVP treatment (12 days after ethanol withdrawal), animals still showed a significantly decreased response to the hypothermic and sedative effects of ethanol, but by 6 days after the end of AVP treatment (15 days after withdrawal), sleep time was not significantly different from that of controls, and the hypothermic

0028–0836/78/0276—0614$01.00

response was returning towards control values. At 18 days after withdrawal, no differences in response were seen between control and ethanol-treated animals injected with AVP (Fig. 1*a*, *b*).

Thus, while the half-life for disappearance of ethanol tolerance after chronic ethanol treatment was approximately 3 days in untreated[8] or saline-treated mice, treatment with AVP maintained this tolerance for as long as hormone administration was continued. Since AVP treatment did not affect the rate of ethanol metabolism either during the drinking period, during withdrawal, or during tolerance testing[10], it is apparently functional (CNS) tolerance to ethanol which is affected by the neurohypophyseal peptide. Treatment of the animals with an equimolar dose of oxytocin, a peptide which differs structurally from vasopressin by only two amino acids (Fig. 2), had no such effect on ethanol tolerance. These results are in agreement with studies on the effects of the peptides in inhibiting extinction of an active avoidance response[1], and with our previous studies regarding the ability of neurohypophyseal hormones to attenuate puromycin-induced amnesia in Swiss-Webster mice[4,11]. In our studies, vasopressin attenuated the amnesia at a dose level at which oxytocin was ineffective[11]. One has to consider that peripherally administered peptides which differ in their primary structure may be metabolised by different pathways[12] and may not be distributed in an equivalent manner within the CNS. On the other hand, oxytocin has been shown to modulate the development of functional tolerance to morphine in rats when administered s.c. at doses which were even lower than those used in our studies[13].

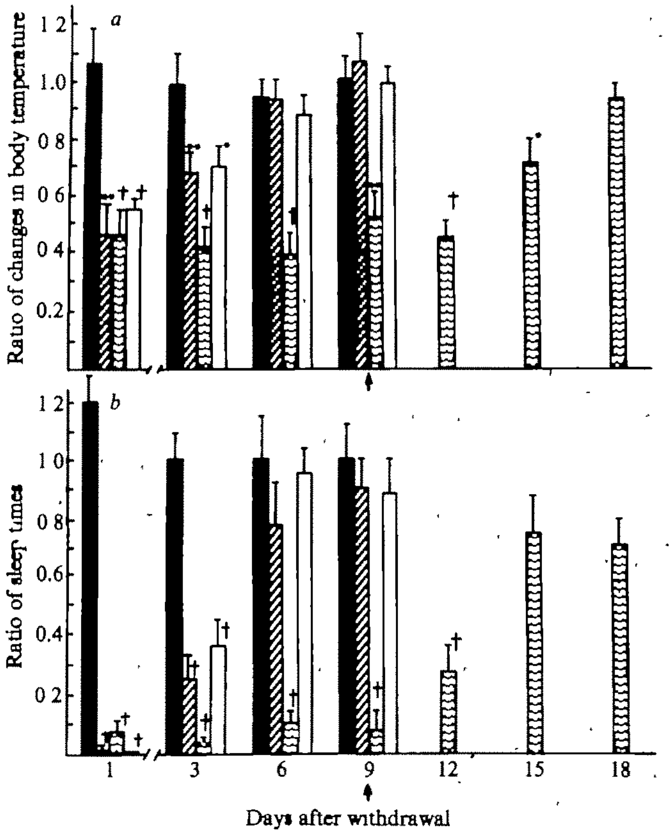

Fig. 1 Response of male C57BL/6 mice to a challenge dose of 3 g per kg ethanol, measured as decrease in body temperature (*a*) or duration of loss of righting reflex ('sleep time'; *b*). Data are presented as the ratio of the response of the ethanol-fed animals which had received various treatments to the response of their respective controls. The ratio of responses of control animals treated with AVP to those treated with saline is also shown. These ratios are less than 1.0 when the ethanol-withdrawn animals are tolerant to the effects of ethanol. As tolerance disappears the ratio approaches 1.0. Ratios were computed by dividing individual responses of animals in the group represented in the numerator by the mean response of animals in the group represented in the denominator; the value in the figure represents the mean ± s.e.m. of the ratios generated. ■, Controls: AVP-treated/saline treated. ■, Ethanol-dependent, saline-treated/saline-treated controls. ▨, Ethanol-dependent AVP-treated/AVP-treated controls. □, Ethanol-dependent oxytocin-treated/oxytocin-treated controls. Significance was determined by comparison (*t* test) of each ratio with the ratio of AVP- to saline-treated controls. Ratios of ethanol-dependent AVP-treated to AVP-treated controls on days 12, 15 and 18 after withdrawal were compared to the AVP/saline control ratio on day 9 after withdrawal, the day that AVP administration was discontinued (↑). †, $P \leq 0.001$; **, $P < 0.01$; *, $P < 0.05$. There were 6–12 animals in each group. The duration of the loss of righting reflex for saline-treated control animals when tested on day 1 after withdrawal was 25.1±2.1 min and body temperature was depressed by 2.2±0.2°C by the challenge dose of ethanol. These values for the AVP-treated control group were 25.8±3.1 min and 2.1±0.2 °C and for the oxytocin-treated controls, 23.4±2.8 min and 2.1±0.3 °C. Similar values were obtained with animals of these groups at other times during the period of testing.

Fig. 2 Primary structure of arginine vasopressin and oxytocin. Nomenclature of peptides is in accordance with recommendations of the IUPAC-IUB Commission on Biochemical Nomenclature[22]. AVP (430 IU mg^{-1}, rat pressor assay[23]) and oxytocin (506 IU mg^{-1}, avian vaso-depressor assay[24]) were supplied by Dr C. W. Smith (Department of Physiology and Biophysics, University of Illinois).

The evidence that neurohypophyseal peptides affect memory-related functions by direct interaction with elements of the CNS has been previously reviewed[1]. We have also found[14] that after s.c. injection of a dose of ^{14}C-labelled AVP[15] comparable to that used in the present study, detectable amounts of radioactivity were present in brain as intact hormone; such results are consistent with an action of AVP in the CNS. Although the doses of AVP administered to our mice were high compared with circulating levels of this hormone, the rapid peripheral metabolism of the peptide hormones dictates the use of doses significantly higher than intraventricularly administered doses which are capable of producing similar behavioural effects. Direct interactions between ethanol and AVP could have contributed to the observed effect of the hormone on ethanol tolerance. During the drinking period, both AVP and ethanol were present in the animal simultaneously. However, further studies in our laboratory[16] have indicated that when AVP injections are begun on the day after ethanol withdrawal, tolerance is still maintained for as long as the AVP treatment continues.

Acute exposure to ethanol inhibits the release of antidiuretic hormone[17], and a recent study showed a rebound increase in urinary AVP excretion after clearance of a single dose of ethanol[18]. It seems that tolerance to the effect of ethanol on AVP secretion did not develop after chronic ethanol treatment[18]. Plasma AVP levels have been reported to be increased in rats at the end of a regimen of repeated ethanol treatments[18] and in chronic alcoholic patients withdrawing from ethanol over a period of 5 days[19]. Furthermore, a selectively bred strain of alcohol-preferring rats, which was demonstrated to have both higher innate tolerance and higher acquired tolerance to ethanol than outbred rats or a strain of alcohol-avoiding rats[20], has also been found to excrete more AVP during 6 h after ethanol intubation than the alcohol-avoiding rats[21]. Thus, the ability of AVP to maintain tolerance to the sedative and hypothermic effects of ethanol after chronic ethanol treatment, which was observed in the present study, may reflect a physiological role of the hormone in modulation of ethanol tolerance.

Increased spontaneous activity following substance P infusion into A10 dopaminergic area

THE polypeptide, substance P, has a discrete regional distribution in mammalian CNS; particularly high concentrations are found in the mesencephalon, close to the origin of the two major ascending dopaminergic pathways[1,2]. Two further observations which may reflect functional neurotransmission are, first, that substance P is released from spinal cord and hypothalamus[3,4], and second, that it has been localised using fragmentation techniques in nerve ending particles of bovine hypothalamus and substantia nigra[5,6]. Further support for this hypothesis comes from iontophoretic studies in which application of substance P into the medial nucleus of amygdala and substantia nigra induced a strong neuronal activation[7,8]. It has also been shown biochemically that the activity of dopaminergic systems may be modulated by substance P neurones[9,10]. The ventral tegmental area (VTA), which contains the cell bodies of the dopaminergic A10 neurones (DA-A10), receives a substance P innervation mainly from substance P cell bodies localised in the medial habenular nucleus[11,12]. DA-A10 neurones give rise to the mesolimbic DA system and also to the mesocortical DA axons innervating cerebral cortical area[13,14]. We have studied the behavioural effects of local application of substance P into the VTA, to try to elucidate the physiological role of substance P innervation of this area. A strong enhancement of spontaneous activity was observed following bilateral infusion of substance P. A major feature of this enhancement was increased exploratory behaviour. Moreover *d*-amphetamine-induced behavioural arousal was potentiated by previous infusion (1 h) of substance P into the VTA.

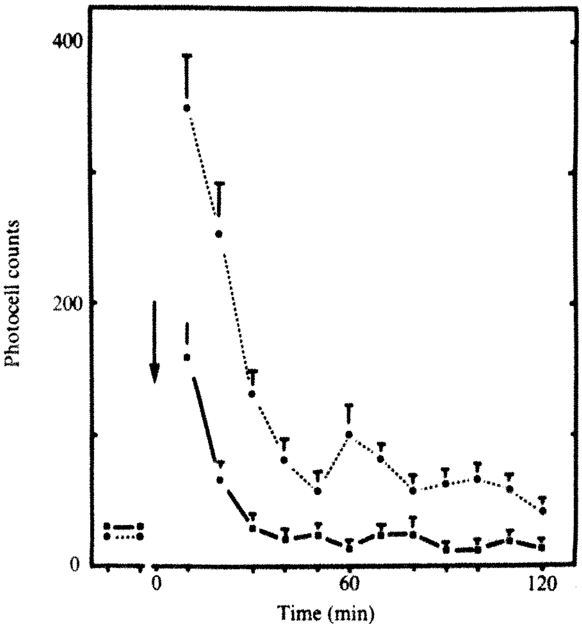

Fig. 1 Effect of acute bilateral infusion into the ventral tegmental area of isotonic saline (——) or substance P (– – – –) on whole body locomotor activity measured in photocell cages. The ordinate indicates the mean photocell counts + s.e.m., the abscissa indicates time by 10-min periods. Arrow, time of infusion. The lines before the arrow reflect baseline activity of the rats during 20 min before injection. The photocell cages were 70 cm × 25 cm and had two beams, which, when broken, registered counts in a recorder outside the testing room. Substance P was infused as a concentration of 3 μg in 1 μl ($n = 14$) and 1 μl of saline was infused ($n = 12$).

Forty-three Sprague–Dawley rats (300–350 g) were implanted with bilateral stainless steel guide cannulae (23 gauge) aimed 3 mm above the VTA. Coordinates were (in mm): 3.5 posterior to bregma, 0.5 lateral from midline, and 5.6 below skull surface (incisor bar 5 mm above interaural line). Histological examination revealed that the 86 infusion sites were well localised in the VTA. Ten days after surgery, 3 μg synthetic substance P or the solvent (1 μl of 0.9% sterile saline) were injected bilaterally by lowering an injection needle (30 gauge) through the guide cannulae to a point 8.6 mm below skull surface; the infusion lasted 120 s and a 60-s diffusion time was allowed before removal of the needles. The substance P dose used in our experiments is considerably higher than the endogenous amounts of this substance in the VTA; however Jessel *et al.* have shown that there is no reuptake mechanism at substance P terminals and that substance P is rapidly catabolised by peptidases in the extracellular space[4]. The experiments were carried out during the least active part of the rat's circadian rhythm (1200–1700), with white noise (67–68 db), constant temperature (20 °C) and illumination (0.14 ft lamberts). Rats were familiarised to the experimental conditions before testing began.

In the first experiment, photocell cages were used to measure whole body locomotor activity. On a test day, the rats were habituated to the cages for 1 h; then saline or substance P infusion into the VTA was made and the rats were returned

0028-0836/78/0276—0616$01.00

immediately to the photocell cages for 2 h. Fourteen rats received synthetic substance P (Bachem) and 12 received saline. Animals injected with substance P in VTA exhibited a pronounced long-lasting increase in spontaneous activity (Fig. 1); analysis of variance indicated a significant group effect ($F = 28.4$, d.f. = 1,24, $P < 0.0001$) and group × time interaction ($F = 35$, d.f. = 11,11, $P < 0.001$). As soon as 20 s after the beginning of a substance P infusion, rats developed a behavioural excitation which was characterised by rearing, sniffing and hypermotility. The strongest effect was apparent during the first 40 min, but it was still in evidence during the subsequent hour.

In order to analyse this behavioural activation further, a second experiment was performed in a white square open field. Since rats have a tendency to avoid the centre area of the open field because of increased 'emotionality' or fear, we measured locomotion and rearing along the walls as well as in the centre area during a 10-min period. Eleven subjects were used as their own controls and were tested on four consecutive days. On the first, third and fourth test days, rats received bilateral infusion of saline into the VTA; substance P was injected on the second test day and all categories of behaviours analysed were enhanced after application (Fig. 2). Analysis of variance over 10 min revealed a significant activation of the following behaviours: locomotion periphery ($F = 5.4$, d.f. = 3,30, $P < 0.01$), rearing periphery ($F = 5.4$, d.f. = 3,30, $P < 0.01$), locomotion centre ($F = 13.9$, d.f. = 3,30, $P < 0.01$), and rearing centre ($F = 6.5$, d.f. = 3,30, $P < 0.01$). Interestingly, motor activity was not homogeneous throughout the open field, and that substance P infusion changed the spatial distribution of locomotion and rearing. The activity in the centre area in saline sessions was 7% of that in the periphery for both locomotion and rearing, whereas this was increased to 20% during the substance P session.

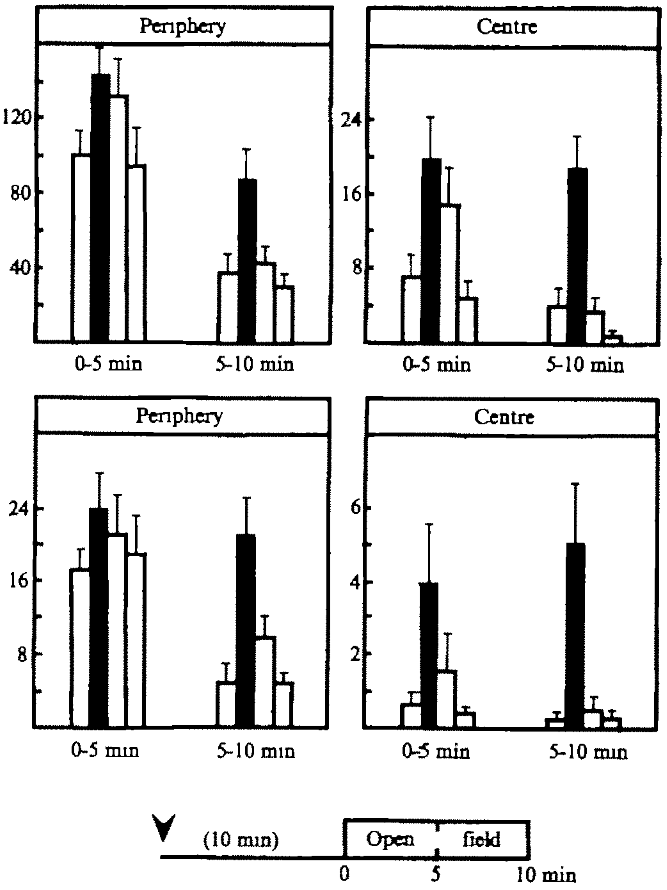
The examination of the drug × time interaction revealed a significant difference in the evolution of rearing between saline and SP sessions (rearing periphery $F = 2.4$, d.f. = 3,30. $P < 0.05$; rearing centre, $F = 4.4$, d.f. = 3,30, $P < 0.01$). This implies that although habituation was observed in saline sessions, during the substance P session rats remained activated throughout the 10 min. Individual comparisons between mean rearing scores on the last 5 min indicated a significant difference between substance P and all saline sessions (Newman-Keuls, $P < 0.01$). Twenty-four hours after the substance P injection motor behaviours in the open field were still elevated above control levels for the first 5 min of the session; but only the increased locomotion at the periphery was significant ($P < 0.01$).

d-Amphetamine-induced locomotor activation is mediated by DA-A10 neurones[15], and the magnitude of the response to *d*-amphetamine is determined by the firing rate of these neurones[16]. To evaluate a possible activation of DA-A10 neurones by substance P, we tested the reaction of 5 rats in photocell cages to a low dose of *d*-amphetamine (0.5 mg per kg i.p.) 1 h after bilateral saline (1 μl) of substance P (3 μg) infusion into the VTA. Four days elapsed between these two test sessions. Substance P significantly potentiated the effect of *d*-amphetamine (activity counts during 1 h after *d*-amphetamine: saline session 333 ± 123, substance P session 1,503 ± 473, $P < 0.001$). The magnitude of this effect cannot be interpreted by the simple addition of the residual substance P effect and the *d*-amphetamine effect, since it is five times that observed after saline infusion.

One problem encountered with intracerebral infusions is that of diffusion to neighbouring structures; it is possible that the substantia nigra (SN), which contains a high amount of substance P, was affected by our injections. We have previously reported, however, that similar injections of substance P into the SN at a point 1.5 mm lateral to the VTA site elicit a syndrome of a quite different nature; consisting of stereotyped movements and, in particular, considerable self-grooming[17]. Infusion of substance P into the VTA induces a behavioural activation characterised by increased exploratory behaviour. An apparent discrepancy to note is that one consequence of lesions of the DA-A10 neurones is a permanent hyperlocomotion[18]. This particular hyperlocomotion, however, is associated with decreased exploration and a disruption of goal-directed behaviour[19]. The activation induced by substance P is interpreted as an enhancement of purposeful and organised behaviours; lesion-induced hyperlocomotion could reflect an inability to attend or to 'focalise' behaviour.

It is possible that the potentiation of the *d*-amphetamine effect after infusion of substance P into the VTA results from increased firing rate of DA-A10 neurones. This is consistent with the ipsilateral increased release of newly synthesised ^{3}H-DA observed in striatum by Cheramy *et al.*[10], after application of substance P into the substantia nigra in the cat. Moreover, the *d*-amphetamine results indicate a long-lasting effect of substance P on DA-A10 neurones. Iontophoretic application of substance P in areas rich in substance P innervation shows a predominant excitation response with slow onset and long duration which is still present between 6 and 15 min after the end of the application[7]. Thus it is possible that VTA substance P-containing neurones, which originate principally in the medial habenular nucleus, exert a tonic activation on DA-A10 neurones. This hypothesis is strengthened by our recent results in which substance P-induced behavioural activation was

Fig. 2 Effects of acute bilateral infusion into the ventral tegmental area of isotonic saline or substance P on locomotion and rearing activities in the open field. Open bars indicate the saline test sessions (first, third and fourth days) and solid bars indicate the SP test session (second day). The locomotion (upper) histograms show the number of squares entered per 5-min period. The rearing (lower) histograms show the number of rears per 5-min period. The peripheral area was the band of squares adjacent to the walls; the centre area consisted of the inner squares. The arrow indicates that infusions were made 10 min befor testing. The open field was 100 cm × 100 cm × 70 cm; the floor was divided into 20-cm squares and locomotion was measured by the number of squares entered. The central area was 60 cm × 60 cm. The rats were transported by hand and placed in the centre of the open field.



blocked by local application of haloperidol in the DA-A10 terminal areas, and by 6-hydroxydopamine-induced lesion of these terminals. Precisely which specific structures are involved in mediating the response to substance P cannot yet be determined. The medial habenular nucleus receives strong afferents from limbic structures such as septum, diagonal band of Broca and nucleus accumbens[20–22], all of which are innervated by DA-A10 neurones. The habenular nucleus also receives dopaminergic input from the VTA[23] and serotonergic afferents from the raphe nuclei[24] which are implicated in the control of DA activity[25,26]. It is proposed that the substance P innervation of the VTA is part of a descending feedback loop which modulates the mesolimbic and mesocortical dopaminergic systems tonically.

Denervation supersensitivity in the striatonigral GABA pathway

POSTSYNAPTIC receptors deprived of their associated presynaptic terminals exhibit denervation supersensitivity by showing enhanced responses to agonist drugs and elevated binding of radiolabelled ligands[1–4]. To investigate whether this effect also occurs in γ-aminobutyric acid (GABA) neurones we have denervated the receptors for a well defined GABAergic projection in the rat brain, using the kainic acid lesion technique, and have found them to show enhanced responses to a GABA agonist drug and correlated elevations in radioligand binding.

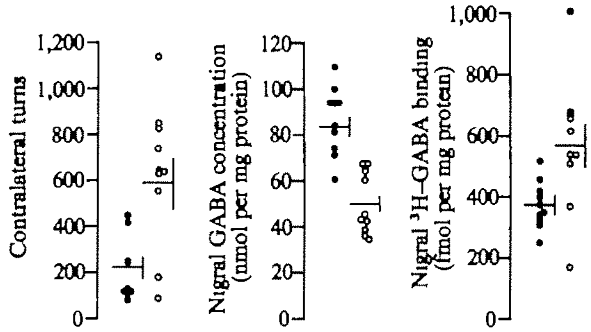

Fig. 1 Left: rotational responses in automated rotometers[20] 1 h after unilateral intranigral injection of muscimol (2 ng; stereotaxic coordinates: A2.2, V-2.8, L2.0, König & Klippel[29]) made 3 weeks after ipsilateral striatal KA lesions (2.5 μg; coordinates A8.0, V0.0, L2.5) or in unlesioned (control) rats. Intracerebral injections were made by slow-motion infusion in 1 μl saline, under light ether anaesthesia for muscimol or barbiturate anaesthesia for KA, as previously described[7,8,15]. Comparisons were by Mann–Whitney U test (2-tailed) ($P < 0.02$). Centre: nigral GABA concentrations in the substantia nigra of lesioned and unlesioned (control) hemispheres of rats 4 weeks after unilateral striatal KA lesions, determined by radioreceptor assay[22]. Comparison by Wilcoxon T test (2-tailed) ($P < 0.01$). Right: specific Na^+-independent high-affinity ^3H-GABA-receptor binding in Triton-treated membrane preparations of substantia nigra from lesioned and unlesioned (control) hemispheres of rats 4 weeks after unilateral striatal KA lesions, using ^3H-GABA at 10 nM (ref. 21). Specific binding was defined as the difference between binding occurring in the presence and absence of an excess (100 μM) of unlabelled GABA. Comparison by Wilcoxon T test (2-tailed) ($P < 0.03$). Protein contents of nigrae dissected from lesioned (116.5±6.5 μg) and unlesioned (113.5±9.5 μg) hemispheres were indistinguishable. ● Control; ○ lesion.

These results indicate that GABA receptors can show denervation supersensitivity and suggest that elevated GABA-receptor binding in Huntington's chorea may be of functional significance for the pharmacotherapy of this disorder.

Using the Ungerstedt rotating rat model[5], in which the nigrostriatal dopamine system in one hemisphere is destroyed by intracerebral injection of the catecholamine neurotoxin 6-hydroxydopamine (6-OHDA), supersensitivity of denervated striatal dopamine receptors is manifested by a contralateral rotational response to peripheral administration of the dopamine-receptor agonist apomorphine. This has been shown to be associated with elevated binding of the dopamine-receptor ligands ^3H-haloperidol[3] and ^3H-spiperone[4], which correlates with the degree of apomorphine-induced turning[4]. The unilaterally 6-OHDA-lesioned rat has provided a useful animal model for the study of the physiology and pharmacology of dopaminergic mechanisms[2–6]. As GABA-dependent, dopamine-independent, contralateral rotational behaviour results from unilateral intranigral injection of GABAergic drugs[7–12], we sought to define a unilaterally GABA-lesioned model to facilitate the study of the physiology and pharmacology of GABAergic mechanisms in an analogous manner to the unilaterally 6-OHDA-lesioned rat. Thus, we destroyed the cell bodies of origin of the striatonigral GABA pathway[13,14] and examined rotational responses to a GABAmimetic drug and ^3H-GABA receptor binding in the putatively denervated nigra.

Male Sprague-Dawley rats, 150–200 g, were given unilateral stereotaxic injections of kainic acid (KA, 2.5 μg in 1 μl saline) to destroy striatal perikarya, including the cell bodies of origin of the striatonigral GABA pathway[16,17]. After 21 d rats were given unilateral intranigral injections of the potent and specific GABA agonist muscimol[18,19] (2 ng 1 μl^{-1}) ipsilateral to the KA lesion, and resulting rotational behaviour was quantified in automated rotometers[20]. After a further 7 d rats were decapitated and nigral tissue dissected from each hemisphere from frozen sections. Specific ^3H-GABA binding in Triton-treated membrane preparations of each nigra was determined using

0028-0836/78/0276—0618$01.00

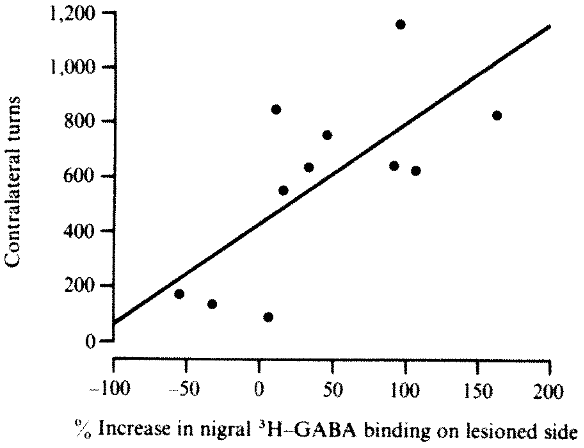
^{3}H-GABA at 10 nM (ref. 21), and nigral GABA levels were determined using a sensitive radioreceptor assay[22].

Unlesioned control rats showed contralateral rotation to this low dose of muscimol administered unilaterally into the substantia nigra[7–11]. In successfully lesioned rats an enhanced rotation was seen when muscimol was administered into the denervated nigra (+173%, $P<0.02$). In these rats, ^{3}H-GABA binding was greater in the nigra of the lesioned hemisphere than in that of the contralateral unlesioned hemisphere (+52%, $P<0.03$), and GABA levels were reduced (−44%, $P<0.01$) (Fig. 1). In lesioned animals there was a significant correlation between rotational response to intranigrally administered muscimol and elevation of nigral ^{3}H-GABA binding ($r=0.686$, $P<0.05$) (Fig. 2).

A Scatchard analysis of saturation data, carried out on the nigra of lesioned and unlesioned hemispheres, revealed that the elevation of ^{3}H-GABA binding in the nigra of the KA-lesioned hemisphere was primarily characterised by an 81% increase in maximal high-affinity ^{3}H-GABA binding (B_{max}), with no change in dissociation constant (K_D). B_{max} for low-affinity ^{3}H-GABA binding was elevated by 37% in the lesioned nigral preparations, with no change in K_D (Fig. 3). This profile of a denervation-induced increase in GABA-receptor sites, without a change in affinity for their ligand, is qualitatively similar to that seen in the dopamine-denervated striatum using ^{3}H-haloperidol as a dopamine-receptor ligand[3].

Rats with denervated nigral GABA receptors showed an enhanced rotational response to the GABA agonist muscimol and elevated nigral binding of ^{3}H-GABA; rotational responses and elevation of ^{3}H-GABA binding were significantly correlated. These findings are consistent with the development of denervation supersensitivity of nigral GABA receptors deprived of their associated presynaptic terminals by destruction of their cell bodies of origin. This GABA-dependent rotational behaviour has been shown to be independent of nigrostriatal dopaminergic mechanisms[7–12], although these effects of GABA agonists may mimic those of dopamine agonists in the 6-OHDA-lesioned rat (that is, induce contralateral rotation) by acting beyond the striatum, at the level of the substantia nigra; the striatonigral pathway has been shown to constitute the striatal output system[23,24]. We therefore propose that our study demonstrates a GABA-dependent rotational behaviour model in which GABAergic parameters, including correlated behavioural and receptor-binding indices of supersensitivity after unilateral lesions of descending GABA pathways, are similar in many respects to their equivalent dopaminergic parameters in the dopamine-dependent rotational model[2–4].

Fig. 2 Correlation between rotational response 1 h after 2 ng muscimol, administered unilaterally into the substantia nigra and elevation of nigral ^{3}H-GABA-receptor binding, after ipsilateral striatal KA lesions. Significant correlation: $r=0.686$, $P<0.05$ (2-tailed). Line of best fit indicates a value of rotation ($\simeq 400$ turns h^{-1}) for zero change in binding that is within the control range of turning for this dose of muscimol administered unilaterally into the substantia nigra of unlesioned rats (see Fig. 1).



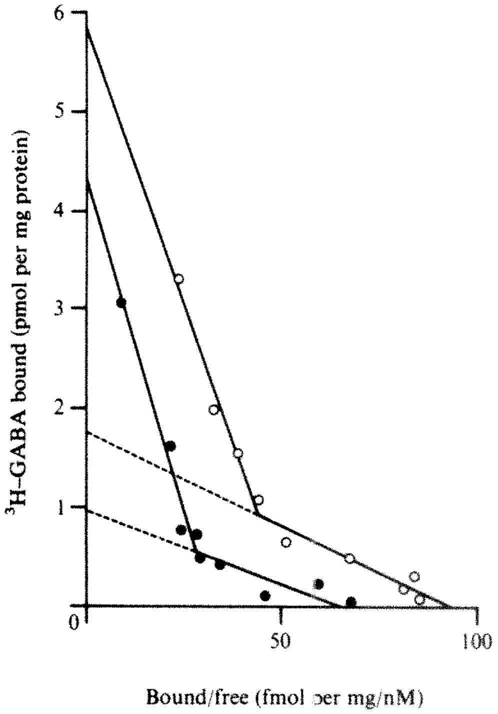


Fig. 3 Scatchard analysis of saturation data from ^{3}H-GABA-receptor binding carried out as described in Fig. 1 using 1–100 nM ^{3}H-GABA, on substantia nigra from lesioned and unlesioned (control) hemispheres of rats with unilateral striatal KA lesions. Maximum binding (B_{max}, fmol per mg protein) and dissociation constant (K_D, nM) for high-affinity ^{3}H-GABA binding were 958 and 15, respectively, in control animals (●), and 1,735 and 18, respectively, in lesioned animals (○). Respective B_{max} and K_D values for low-affinity ^{3}H-GABA binding were 4,234 and 130 in controls, and 5,831 and 112 in lesioned animals. Results are from pooled tissue of a further 6 lesioned animals.

The results demonstrate for the first time a correlation between receptor supersensitivity as indexed by a behavioural test and a ligand binding technique in a non-dopaminergic system. This model may be useful for studying the physiology and pharmacology of GABAergic mechanisms.

In addition, the striatal KA lesion has been proposed as a biochemical[16,17] and behavioural[25] model for Huntington's chorea. Our demonstration of GABA supersensitivity in the substantia nigra after such lesions provides additional support for the validity of this model, as the substantia nigra in post-mortem brains from choreic patients shows elevated ^{3}H-GABA binding[26]. Our study also suggests that, contrary to previous suggestions[27], GABA agonists may be of limited therapeutic potential in this condition. By acting on such supersensitive nigral GABA receptors at the level of the striatal output system, they may mimic those effects of increased dopaminergic transmission that are thought to be detrimental to clinical state in Huntington's chorea[28].

Calcium-dependent exocytosis in bovine adrenal medullary cells with leaky plasma membranes

SECRETION from nerve terminals and many other cell types occurs by exocytosis, a process in which the contents of small intracellular vesicles are released after fusion of the vesicle membrane with the plasma membrane of the cell. Exocytosis generally requires calcium ions[1,2], but little is known about the site at which these Ca ions act. The electrophysiological experiments of Katz and Miledi[3] strongly point to an intracellular site, a conclusion that is supported both by the observation that transmitter release is increased after microinjection of Ca into the presynaptic terminal of the squid giant synapse[4] and the finding that the Ca ionophore A23187 promotes secretion from a variety of cells[5]. Further progress has been severely hampered by lack of preparations in which this presumed intracellular site is freely accessible to experimental investigation. We now present evidence that the plasma membrane of medullary cells from the bovine adrenal gland can be rendered permeable to small molecular weight substances without blocking Ca-dependent exocytosis. This preparation has been used to examine the dependence of exocytosis on Ca and Mg ions.

Cells were obtained from thin slices of bovine adrenal medulla by protease digestion[6]. Catecholamine can be released in a Ca-dependent manner by stimulation with carbamylcholine, veratridine or potassium chloride. The Ca-dependence of catecholamine release in response to these secretagogues is shown in Fig. 1. In all cases secretion is half-maximal at Ca concentrations between 0.1 and 1 mM, and is associated with the release of the vesicular enzyme dopamine-β-hydroxylase but note cytosolic enzyme lactate dehydrogenase. Secretion is inhibited by the Ca channel blocker D600 (10^{-4} M).

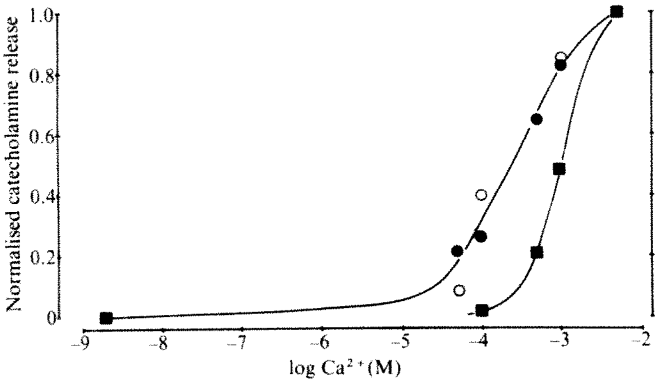

Fig. 1 Ca-dependence of catecholamine release from intact bovine adrenal medullary cells in response to 5×10^{-4} M carbamyl choline (●), 5×10^{-4} M veratridine (■) and to a potassium challenge (○). Ordinate: catecholamine release normalised to that in 5 mM Ca. Catecholamine was assayed fluorimetrically by the trihydroxyindole method[7]. Incubation was for 15 min at 37 °C after which time the cells were removed by centrifugation and samples of the supernatant taken for analysis. The medium contained (mM) NaCl, 136; KCl, 2.7; glucose, 5; Mg, 2; HEPES, 16 *p*H 7.2 and for the potassium challenge NaCl, 68; KCl, 70.7; glucose, 5; Mg, 2; HEPES, 16 *p*H 7.2. The media containing 2×10^{-9} M Ca^{2+} (calculated) contained in addition 5 mM EGTA.

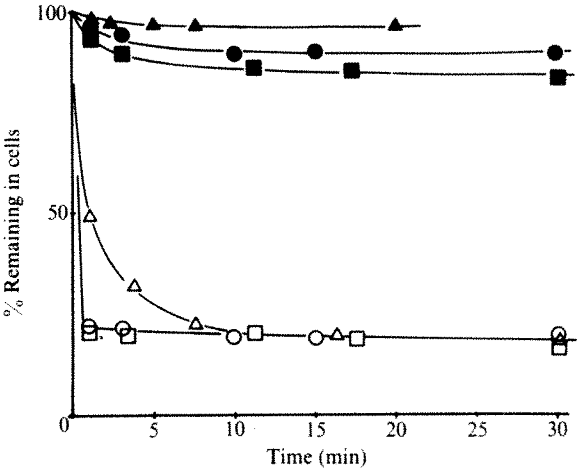

Fig. 2 Release of ^{86}Rb and catecholamine after exposure to high-voltage discharges. 1 ml of a suspension of medullary cells (10^6 per ml) preloaded with ^{86}Rb was placed between a pair of stainless steel electrodes (0.9 cm apart and each 1.0 cm^2) in a square perspex container and subjected to the discharge of a 2 μF capacitor. Cells exposed at zero time to 1 (▲, △), 5 (●, ○) and 10 (■, □) discharges, τ approx 200 μs. Field 2 kV cm^{-1}. Medium (mM): potassium glutamate, 138.7; glucose, 5; Mg, 2; PIPES, 20 *p*H 6.6; Ca-EGTA buffer, 5. Calculated free Ca^{2+} 10^{-5}M. Temperature 37 °C. Closed symbols represent catecholamine release and open symbols ^{86}Rb release. Similar results were obtained with cells preloaded with the non-metabolisable sugar 3-*O*-[^{14}C]methyl-D-glucose showing that the increase in permeability is not restricted to charged molecules.

To provide ready access to the cell interior, suspensions of cells were exposed to a small number of high-voltage discharges[8]. This technique was used previously to alter the intracellular environment of erythrocytes[9,10]. It presumably works by causing localised dielectric breakdown generating holes in the plasma membrane. This increase in permeability is most readily demonstrated in cells preloaded with ^{86}Rb where a suitable shocking regime can release 80% of the cellular ^{86}Rb within a few minutes (Fig. 2). As we wished to gain ready access to the cell interior for Ca-EGTA buffers, we also examined the uptake of ^{51}Cr-EDTA. In conditions similar to those used in Fig. 2, the ^{51}Cr-EDTA space increased within 5 min to a new steady level that varied between 50 and 75% of the cell volume. This suggests that the cells should have also been rendered freely permeable to Ca-EGTA which is only a little larger than Cr-EDTA. Although erythrocytes reseal after exposure to high voltage discharges, this does not seem to happen in adrenal cells where measurements of the ^{51}Cr-EDTA space show that the cells remain freely permeable for at least 20 min at 37 °C.

0028-0836/78/0276—0620$01.00

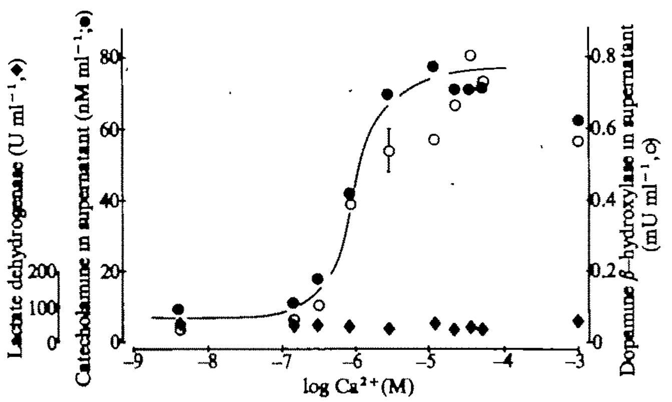

Fig. 3 Ca-dependence of catecholamine (●); dopamine-β-hydroxylase (○), and lactate dehydrogenase (◆) release in response to five discharges (2 kV cm^{-1}, $\tau \sim 200$ μs) over about 30 s. The samples were centrifuged and assayed 15 min after the discharges. Medium (mM): potassium glutamate, 138.7; glucose, 5; Mg^{2+} 2; PIPES, 30; Ca-EGTA buffer, 5; *p*H 6.6. Temperature 37 °C. Catecholamine was assayed fluorimetrically[7]. Dopamine-β-hydroxylase was assayed spectrophotometrically by measuring conversion of tyramine to octopamine[11]. Lactate dehydrogenase was assayed spectrophotometrically[12].

When cells are exposed to high-voltage discharges in media containing Ca, catecholamine is released (Fig. 2). This release is Ca-dependent, but is not mediated by depolarisation nor does it involve Ca channels. Release is not brought about by the temperature jump generated by the high-voltage discharge. Less than 1% of the total intracellular catecholamine is normally released after exposure to high-voltage discharges in nominally Ca-free media containing EGTA though the cells are rendered freely permeable to Cr-EDTA. With calcium present more than 10% of the total catecholamine is released and this response persists unchanged in cells fully depolarised by potassium and in the presence of a Ca channel blocker D600 (10^{-4} M). This Ca-dependent release of catecholamine seems to reflect exocytosis because it is associated with the selective release of the vesicular enzyme dopamine-β-hydroxylase but not lactate dehydrogenase which is present in the cytosol and is very temperature-dependent, being reduced by over 90% when the temperature is lowered from 37 °C to 5 °C. The catecholamine release is unlikely to result from a direct effect on the vesicles because exposure of isolated chromaffin granules to the same shock regime gives no release of catecholamine or dopamine-β-hydroxylase.

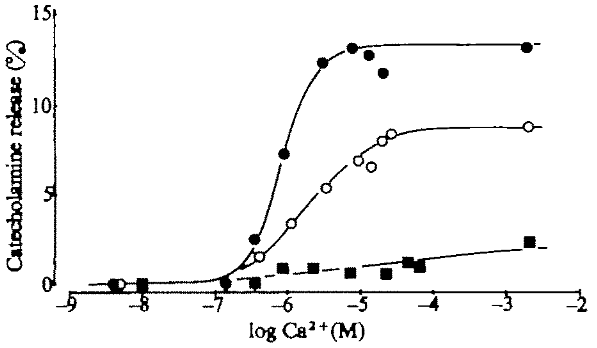

Fig. 4 Ca-dependence of catecholamine release at different magnesium levels in response to five discharges of 2 kV cm^{-1}. The samples were centrifuged and assayed 15 min after the discharges. Medium (mM): potassium glutamate, 138.7; glucose, 5; PIPES 20; Ca-EGTA buffer, 10.4, *p*H 6.6; $MgCl_2$ 2, (●); 10, (○); 50, (■). Temperature 37 °C. The time constant of the discharge is dependent on the conductivity of the medium and would have been close to 200 μs for media containing 2 mM $Mg\ Cl_2$ and 140 μs for media containing 50 mM $Mg\ Cl_2$.

Working with cells rendered permeable by exposure to high-voltage discharges, we have investigated the dependence of exocytosis on the level of ionised Ca and Mg in the medium in which the shocks are delivered. Using two Ca-buffers, EGTA (Fig. 3) and EDTA, the Ca concentration giving half-maximal activation of the release of both catecholamine and dopamine-β-hydroxylase is close to 1 μM in the presence of 2 mM Mg. This is more than two orders of magnitude lower than the Ca concentration required for half-maximal activation of secretion from intact cells (Fig. 1), providing further evidence that exposure to high voltage discharges renders the interior of the cell freely accessible to externally applied Ca-buffers. Figure 4 shows that raising the Mg concentration both reduces the apparent affinity for Ca and also leads to a decrease in the total amount of catecholamine released.

Another interesting feature of Figs 3 and 4 is that only about 10% of the total cellular catecholamine and dopamine-β-hydroxylase is released even though the cells are freely permeable to Cr-EDTA. At first sight this is very surprising as one might expect that if Ca has free access to an intracellular site controlling exocytosis all the vesicular catecholamine and dopamine-β-hydroxylase should ultimately be released. There may, however, be only a limited number of release sites and the conditions used in our experiments may not permit repriming these sites for more than one round of exocytosis.

In all these experiments cells have been suspended in the test medium and then exposed to a series of high-voltage discharges. This means that the site at which Ca acts is still exposed to a fairly normal intracellular environment. In order to probe further the ionic and metabolic requirements for exocytosis it is necessary to render cells freely permeable in the absence of Ca and only expose them to Ca after adequate time has been allowed for small molecular weight materials to equilibrate. Figure 5 shows that this is technically possible. Preliminary results indicate that after exposure at 37 °C for longer than 5 min to Ca-free solutions lacking ATP, addition of Ca fails to promote exocytosis whereas Ca remains fully effective for at least 30 min provided ATP is present throughout the period of exposure to nominally Ca-free media. These results suggest that ATP or something derived from it is necessary for Ca-dependent exocytosis in adrenal medulla cells. A similar conclusion had been reached from experiments on intact cells[13,14], but the present preparation seems to offer an excellent opportunity to discover the part played by ATP in exocytosis. Recently there have been a number of claims that Ca-dependent exocytosis can occur in cell-free systems[15–17]. A feature common to these systems and the present preparation is that all are activated by micromolar

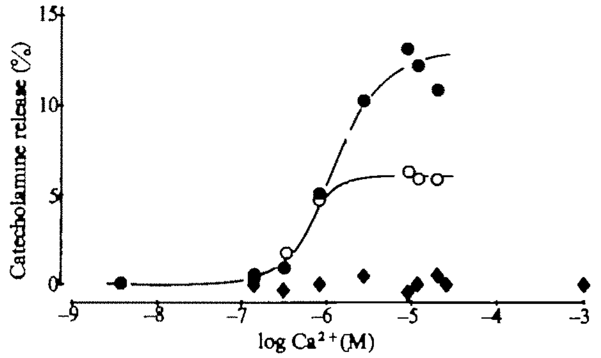

Fig. 5 Influence of ATP on Ca-dependent catecholamine release. Ten discharges 2 kV cm^{-1}, $\tau \sim 200$ μs were applied to cells in a medium of (mM): potassium glutamate, 138.7; glucose, 5; PIPES, 20; EGTA, 0.4; ATP, 0 (◆), 1 (○), 5 (●); *p*H 6.6. The cells were incubated for 30 min at 37 °C and then Ca-EGTA buffer at *p*H 6.6 was added to give a final buffer concentration of 10 4 mM. After a further 15 min at 37 °C the samples were centrifuged and assayed.

0028-0836/78/0276—0621$01 00

concentrations of Ca which seems well within the physiologically possible range[18]. It is also within the range in which troponin and related Ca-binding proteins are activated.

Depolarising effect of curare on embryonic rat muscles

CURARE (*d*-tubocurarine) reduces the responsiveness of skeletal muscle fibres to nerve stimulation[1] by acting as a competitive antagonist to the transmitter acetylcholine (ACh)[2]. In adult muscle this action is not accompanied by any obvious change in muscle fibre resting potential, such as is produced by depolarising blocking agents[3]. We report here that in rat embryos curare evokes large depolarisations through action on ACh receptors.

Experiments were carried out on internal intercostal muscles from rat embryos (15–20 d gestation) and neonatal pups, with standard recording techniques[4]. During this developmental period intercostal muscles differentiate from primary myotubes to myofibres[5]. At all ages studied the muscle cells had resting membrane potentials of −70 to −90 mV in normal saline solution (see legend to Fig. 1), most displayed both spontaneous miniature endplate potentials (m.e.p.ps) and nerve-evoked endplate potentials (e.p.ps), and nerve stimulation produced contraction. When these preparations were perfused with medium containing 1–10 μM curare (Calbiochem; Sigma), the recorded resting potentials fell to about −50 mV (Table 1), m.e.p.ps were reduced in amplitude or absent, evoked e.p.ps were small and the muscles gave only a weak contraction in response to nerve stimulation. When the curare was washed out the resting potentials recovered gradually and e.p.ps and m.e.p.ps reappeared. In some cases, we recorded from individual myotubes continuously during the application and washout of curare. The membrane potential in these fell from about −80 mV to about −50 mV in 10–14 min and returned to normal 16–20 min after washing. Presumably, most of this time was required for equilibration of curare in the bath.

Fibres depolarised by bath-applied curare did not desensitise. Reduced resting potentials (~ −50 mV) were still recorded after muscles had been in 10 μM curare for 2 h or more. A similar absence of desensitisation has been reported for dissociated embryonic rat myotubes depolarised by ACh[6].

A depolarising response was also seen when curare was applied focally from a micropipette. Glass microelectrodes were broken to tip openings of 5–15 μm and filled with a 0.5 mM solution of curare in saline; this was ejected by applying 0.5–1 kg cm^{-2} pressure in pulses of 0.1–2 s duration. Curare application by this means frequently produced localised regions of contraction in embryonic muscle. Intracellular recording revealed that during focal curare application the fibres are transiently depolarised by as much as 35 mV (Fig. 1). Some responses exceeded threshold and gave rise to action potentials (Fig. 1*b*). The amplitude of the response elicited was graded with the duration and pressure of the pulse and with the proximity of the curare pipette to the recorded myofibre. The effect did not seem to depend on the action of curare on presynaptic nerve terminals[7], because (1) the depolarising response could be evoked by focal curare application anywhere along the length of the myotubes, (2) focal application did not increase the frequency of spontaneous m.e.p.ps before their abolition, and (3) the response was undiminished by the presence of 0.5 μg ml^{-1} tetrodotoxin in the bath. As a control against possible artefacts arising from the pressure application technique, 15 fibres were subjected to similar pressure pulses from pipettes containing saline solution alone; none responded with depolarisations like those seen with curare (in several cases rapid depolarisations or hyperpolarisations of 2–5 mV were produced by the pressure pulse).

Two lines of evidence indicated that the effect of curare results from action on ACh receptors with a consequent increase in ionic conductance, as occurs during normal neuromuscular transmission. First, the effect of curare was abolished by preincubating the muscle in saline solution containing α-bungarotoxin, which binds ACh receptors with high specificity[8,9]. Embryonic muscles (16 d) were incubated with 5 μg ml^{-1} toxin for 2 h, the unbound toxin was washed out and myotube resting potentials were sampled before and after adding 10 μM curare to the bath (Table 1). The curare had no effect on membrane potential after incubation in the toxin. Likewise, preincubation of muscles in the toxin prevented the phasic myofibre depolarisation and contraction evoked by focal application of curare (as in Fig. 1). Second, curare application reduced myofibre input resistance. Resistances were monitored by application of negative inward current pulses through the recording microelectrode, by means of a bridge circuit. After a single pulse of curare to the surface of myofibres, the input resistance dropped by up to 85% during the rising phase of the depolarisation (Fig. 1), and then gradually returned to its original value, 20–50 MΩ. In contrast, no comparable changes in resistance were detected when the fibres were depolarised (by as much as

Table 1 Membrane potentials recorded in various conditions from rat muscle fibres

	Membrane potential (mV)		
Age	Saline	Saline + curare	Saline + curare (preincubated in α-bungarotoxin)
15–16 d gestation	75.6 ± 0.9 (120/20)	48.3 ± 2.4 (21/3)	76.7 ± 1.7 (18/2)
17–19 d gestation	76.7 ± 0.6 (164/16)	47.0 ± 0.5 (130/15)	
0–3 d postpartum	70.1 ± 1.0 (52/8)	51.1 ± 0.8 (53/5)	
5 d–4 wk postpartum	63.6 ± 1.0 (18/2)	65.8 ± 0.6 (190/10)	
Innervated adult	84.3 ± 0.8 (35/3)		
Denervated adult	62.7 ± 0.9 (42/3)	64.8 ± 0.8 (56/3)	

The values indicate mean ± s.e.m. (no. of fibres per no. of muscles). Curare concentrations were 1–10 μM when applied to embryonic and neonatal muscles, and 0.5 mM when applied to denervated muscles. Curare was applied 20–120 min before potentials were recorded. Muscles preincubated in α-bungarotoxin were exposed to 5 μg ml^{-1} for 2 h.

0028-0836/78/0276—0622$01.00

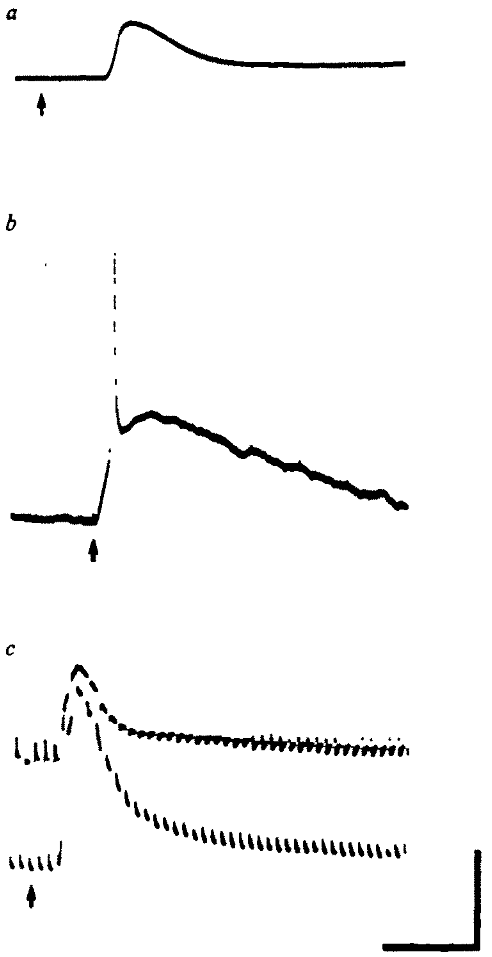

Fig. 1 Muscle fibre depolarisations evoked by focal curare application. Responses from different fibres, without (*a*, *c*) and with (*b*) an accompanying action potential. Curare was applied at the times indicated by arrows by the method described in the text. In *c*, fibre input resistance was monitored synchronously by injecting hyperpolarising current pulses of 50-ms duration and 1-nA amplitude at 300-ms intervals; the amplitude of the potential changes evoked by the current pulses was proportional to membrane resistance. It can be seen that the resistance decreased by 85% in this fibre during the curare response. Note that only partial repolarisations occurred during the intervals illustrated; characteristically, full recovery of the resting potential occurred within one or a few minutes of local curare application. Vertical calibration, 40 mV in *a* and *c*, 10 mV in *b*. Horizontal calibration, 4 s in *a* and *c*, 10 s in *b*. All experiments were done at room temperature (18–21 °C) in oxygenated saline containing 1–5% calf serum and (in mM): NaCl, 118; KCl, 3.0; $CaCl_2$, 4.0; $MgCl_2$, 1.1; glucose, 5.5; HEPES, 4.2 (*p*H 7.2).

50 mV) by raising external potassium to 50 mM through substitution for sodium. These results suggest that the curare acts on ACh receptors to produce an increase in membrane permeability.

The sensitivity of embryonic muscle fibres to curare disappeared at about the time of birth (21–22 d gestation). Of eight muscles examined 0–3 d postpartum, five were depolarised by 10 μM curare in the bath and three were not. The phenomenon was not observed in 10 muscles examined ≥5 d after birth.

As neonatal rat ACh receptors have some properties in common with extrajunctional receptors of denervated adult muscle[10–12], we considered the possibility that adult extrajunctional receptors might also be depolarised by curare. We denervated intercostal muscles in three adult rats and one week later confirmed that they were supersensitive to focally applied carbamylcholine. However, none of the fibres sampled in these muscles was depolarised by 0.5 mM bath-applied curare (Table 1), and none of 10 fibres was depolarised by focally applied 5 mM curare. This agrees with previous studies of the blocking action of curare on denervated rat diaphragm[13,14], in which no depolarising action was observed. By this criterion, then, the receptors of embryonic muscle differ from extrajunctional receptors of adult muscle.

Thus a depolarising response to curare seems to occur only in embryonic muscle fibres. One interpretation of this action is that a third type of ACh receptor exists on mammalian muscle, in addition to the well known junctional and extrajunctional receptors. Ritchie and Fambrough[15] previously suggested that the "molecular identity of the receptors" on rat myotubes may differ from those on normal and denervated adult muscle, on the basis of reversal potentials for ACh-evoked responses. An alternative interpretation, which does not assume a new class of receptors, is that some feature of the membrane environment, such as fluidity, changes in a manner such that the same curare–receptor interaction initially has a channel-opening effect and later does not. Whatever the modification involved in the loss of responsiveness to curare, it must occur soon after birth. It is interesting that one week after birth there is also a marked shift in the gating properties of ACh-activated conductance channels in rat muscle[16].

Effect of tetraethylammonium on noradrenaline release from cat spleen treated with tetrodotoxin

EXPERIMENTS by Katz and Miledi[1] on the giant synapse of the squid stellate ganglion pretreated externally with tetrodotoxin (TTX) to block the conducted nerve impulses, and internally with tetraethylammonium (TEA) to block the potassium current, showed that a local regenerative response confined to the presynaptic terminal was obtained on depolarisation, provided that the external calcium concentration was sufficiently high. Strontium and barium substituted for calcium, and manganese and magnesium reduced the regenerative response. TEA, in the presence of TTX, also caused a massive release of acetylcholine from the frog neuromuscular junction in response to a depolarisation of the motoneurone terminals[2]. These results offered direct evidence for the existence in the nerve terminals of a TTX-resistant calcium channel involved in transmitter release, and suggested that TEA, by allowing an inward calcium

0028-0836/78/0276—0623$01 00

Table 1 Effect of TEA on ^{3}H-NA release in TTX-treated spleen slices

	Fractional release per stimulus $\times 10^{2}$ (% of tissue ^{3}H-NA)				
	Krebs	TTX	TTX + TEA	TTX + TEA (calcium free)	TTX + TEA + lanthanum
^{3}H-NA	2.1 ± 0.4 (12)	0.3 ± 0.1 (12)	3.4 ± 0.7 (9)	0.2 ± 0.04 (9)	0.3 ± 0.1 (9)

All solutions contained phenoxybenzamine (1 µg ml^{-1}). ^{3}H-NA was released by applying field stimulation pulses for 20 or 50 s at 1 Hz. Release per stimulus is expressed as a percentage ($\times 10^{2}$) of tissue ^{3}H-NA content at the time of stimulation. Concentrations: TTX, 0.32 µM; TEA, 10 mM; lanthanum, 1 mM. Numbers in parentheses refer to the number of experiments.

current to become regenerative, enhanced transmitter release. The release of noradrenaline (NA) from sympathetic nerves also requires calcium, and further, strontium and barium substitute for calcium in sustaining release, and magnesium, manganese and lanthanum block release[3]. Moreover, TEA has also been shown to enhance NA release after electrical stimulation of sympathetic nerves[4–6]. These observations suggest that a calcium channel also exists in the sympathetic nerve terminals and is responsible for the release of NA. The present investigation was undertaken to determine if in the presence of TEA and TTX, depolarisation of the sympathetic nerve terminal initiates a 'regenerative' inward calcium current which leads to an explosive release of NA. We report that it does.

Cat spleen slices (1 mm thick) were incubated in ^{3}H-NA solution (16 ng ml^{-1}, specific activity 10.43 Ci mmol^{-1}) to label the endogenous stores of NA[7]. A slice was then transferred to a superfusion chamber which consisted of two halves of plexiglass with a hollowed-out chamber of about 1 ml capacity. Two chloride-coated silver-wire coils, arranged in parallel, served as electrodes and the slice was wedged between them. The open ends of the chamber held small stainless-steel tubes to a polyethylene tube, through which the superfusion fluid was introduced at the bottom and collected from the top. Superfusion was started with oxygenated Krebs–bicarbonate solution containing phenoxybenzamine (1 µg ml^{-1}) at 35 °C. The perfusion rate was about 8 ml min^{-1}. When spontaneous efflux of radioactivity had diminished to low and relatively constant levels, rectangular pulses (1 Hz, 20–80 V, 5 ms) were applied for 20 or 50 s. Effluent samples were collected for 2 min. Total tritium and ^{3}H-NA contents of the samples and the tissue were measured[8]. The increase in ^{3}H-NA release by nerve stimulation was obtained by subtracting the control background activity of the same volume of solution from the total output during stimulation. ^{3}H-NA release per stimulus is expressed as a percentage of the tissue radioactivity before stimulation.

Table 1 shows that ^{3}H-NA output due to field stimulation of sympathetic nerves was markedly reduced in the presence of TTX (0.32 µM). This blockade of release by TTX suggests that the field stimulation-induced release was mainly due to propagated action potentials. Residual release in the presence of TTX must be ascribed to the electrotonic depolarisation of the sympathetic nerve endings by current pulses applied by field stimulation, as in experiments in nerve terminals of the squid[9]. In the presence of TEA (10 mM), however, this residual response in the presence of TTX was restored to the control response obtained before TTX treatment. Secretory response in TEA plus TTX solutions occurred over a narrow range of voltages, and also at voltages much lower than those required to produce even a minimal response from preparations treated with TTX alone. This suggests that the release in the presence of TEA is not graded but may be triggered in a regenerative manner. Removal of calcium or addition of lanthanum (1 mM) abolished the response.

Our results show that in the presence of TEA, depolarisation of the sympathetic nerve terminals treated with TTX produced a massive release of ^{3}H-NA. The effect of TEA was restricted to nerve terminals, as conduction of nerve impulses was never restored at a time when explosive release from nerve terminals by local depolarisations could be demonstrated. Katz and Miledi[1,2] have previously discussed the possibility that inactivation of potassium efflux by TEA during depolarisation enables an inward calcium current to become regenerative. As TEA modifies NA release from sympathetic nerves in a manner comparable with its action on acetylcholine release from motoneurone terminals, it is possible that TEA may act similarly on the voltage-sensitive calcium channels in the sympathetic nerve terminals to facilitate calcium entry. We therefore suggest that one possible reason for the massive release of transmitter from TTX-treated preparations is the regenerative entry of calcium ions induced by the action of TEA on the sympathetic nerve terminals.

We thank Professor R. Miledi for his comments and suggestions. This work was supported by USPHS grant 1 R01 HL22170-01.

Cell adhesion mediated by glycolipids

ADHESION between adjoining cells is a fundamental biological event, preceding both morphogenesis and organogenesis and also providing the basis for cellular recognition and membrane fusion[1–4]. Adhesion is apparently mediated by carbohydrate moieties on the plasma membrane as shown in studies of sugar transferases[5–7] and glycosidases[8]. A number of mechanisms such as the antigen–antibody reaction[9,10], the specific sugar transferase–substrate complex formation[11] and hydrogen bonding[11] between closely opposing carbohydrate chains have been proposed for the specific and nonspecific adhesion of cells, but the relevant surface molecules have not yet been isolated or identified. Two types of cell adhesion have been described: one is the reaggregation of dissociated animal cells in serum which may involve antibodies[9,10] or unidentified components of serum such as the conglutinin[12]. A second type of adhesion occurs in the absence of serum, and is probably regulated by glycoprotein factors[13,14]. Recently we found that lipid particles containing phospholipids or glycolipids were agglutinated by serum and that glycolipid particles adhered most strongly to tissue culture cells even in the absence of serum[15]. We report here that lipids, in particular glycolipids, could mediate adhesion of animal cells.

To determine which particular glycolipids can mediate adhesion, a model system was used involving lipid particles and monolayers of tissue culture cells as adhesion partners. Glycolipids, either prepared by chemical synthesis or isolated from natural sources, were incorporated into lipid particles and tested for adhesiveness on various tissue culture cells (for experimental details see legends to Table 1 and Fig. 2). These experiments

0028–0836/78/0276—0624$01.00

showed that the lipid particles adhered most strongly to HeLa cells and less strongly to other cells in the following decreasing order: BHK > MDCK > 3T3 > MDBK > chick fibroblasts. These results suggest that the various cells contain differing numbers of combining sites in their plasma membranes. As the lipid particles were found to adhere most strongly to HeLa cells, these cells were used to test which lipids most effectively mediated adhesion. To measure the extent of adhesion, fluorescent lipids[16], either dansylcerebroside or dansylsphingosine, were used. The relative adhesiveness of the different lipid particles, measured by the intensity of their fluorescence, is summarised in Table 1. Comparable results were obtained when adhesion was estimated using a UV microscope. It can be concluded from Table 1, that although all lipid particles tested adhered to HeLa cells to varying extents, those particles containing galactose at the terminal positions were the most adhesive. Glycolipids with glucose, fucose, galactosamine or neuraminic acid at their terminal positions were less adhesive to monolayers. The galactose specificity is in accordance with the results of Chipowsky *et al.*[7] and Weigel *et al.*[18] who showed that 3T3 cells could most efficiently adhere to agarose beads which contained galactose as the ligand. Furthermore, the present experiments showed that adhesiveness increased with growing chain length of the sugar moiety. Glycolipids possessing four sugar molecules were the most adhesive of those tested—an exception was sulphatide, which is very adhesive although containing only one galactose molecule. The negative charge imparted by the sulphate group of the sulphatide does not seem to be the direct cause of its strong adhesion capacity, as other negatively charged lipids,

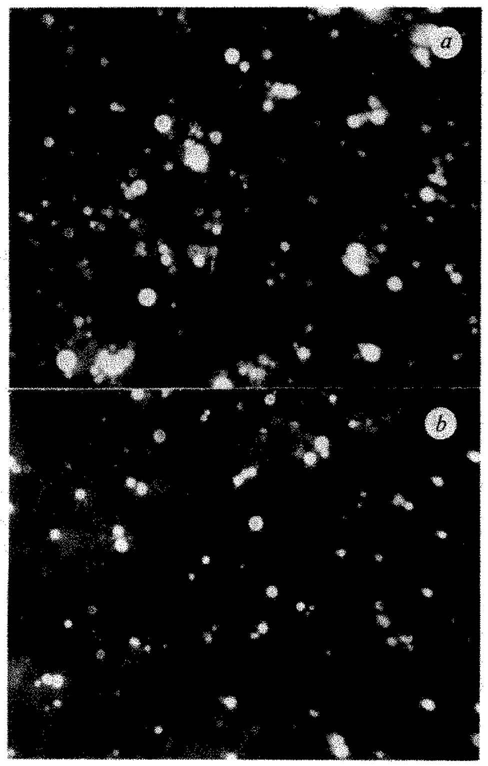

Fig. 1 Adhesion of glycolipid (ceramide-tetraoside, Table 1, compound *L*) particles to monlayers of HeLa cells and BHK cells. *a*, Adhesion to HeLa cells. *b*, Less extensive adhesion to BHK cells. To study adhesion, monolayers of tissue culture cells grown in Serva medium PM 13 to confluency in 5-cm diameter Petri dishes were switched to 2.5 ml of Dulbecco's medium[30] without serum. Aliquots of 0.1 ml of a suspension of glycolipid particles in PBS containing about 10^6 particles were added and the dishes were incubated for 2 h at 37° C. After the incubation period, the medium was decanted and the dishes were rinsed four times with PBS and observed using a UV microscope (Leitz).

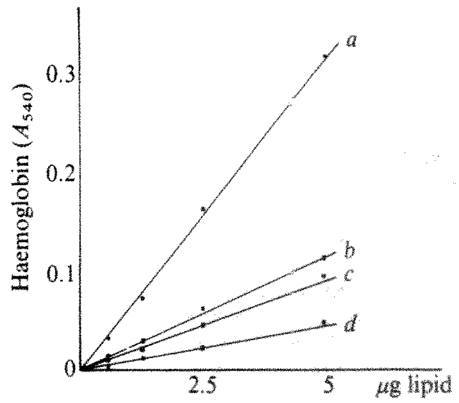

Fig. 2 Effect of glycolipids on the adhesivesness of erythrocytes to HeLa cells. *a*, Ceramide-tetraoside; *b* oligoglucoside; *c*, sphingomyelin; *d*, phosphatidyl inositol. Most lipids listed in Table 1 could be dissolved or finely emulsified in PBS by ultrasonic treatment. In the case of ceramide monohexoside, solubilisation was aided by addition of Tween 20 at a detergent to lipid ratio of 1:1. 100 μl of washed, neuraminidase-treated chick erythrocyte suspension containing 10 μl of packed cells was incubated at 37° C for 45 min with 100 μl of a PBS solution of lipid in the indicated amounts. After the incubation period, erythrocytes were washed three times with PBS. About 10^6 treated erythrocytes were incubated with HeLa cells as described for lipid particles (Fig. 1). The amount of adhered erythrocytes was determined as described in the legend to Table 1. Neuraminidase treatment of erythrocytes enhanced the effect of glycolipids. The standard condition of 0–5 μg of lipid per 100 μl of incubation mixture and an incubation period of 45 min was chosen, as a much higher concentration (>20 μg per 100 μl) of lipid and a prolonged incubation period (>1.5 h) may cause some haemolysis with long-chain glycolipid-treated erythrocytes.

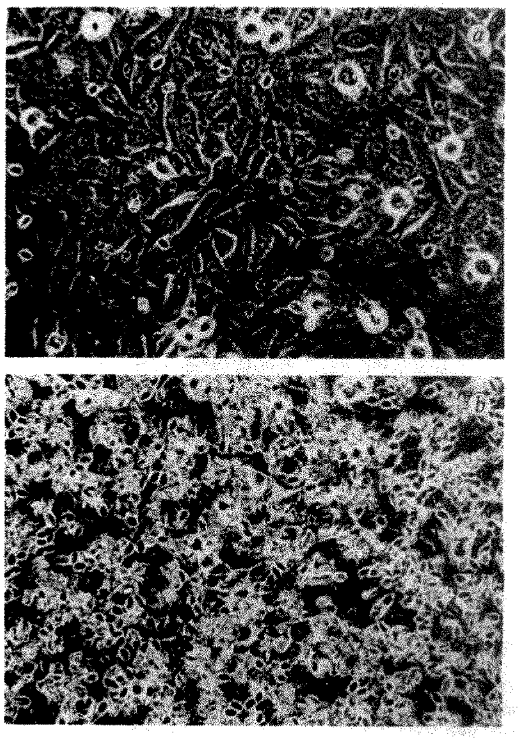

Fig. 3 Adhesion of erythrocytes to HeLa cells. *a*, Scant adhesion of neuraminidase treated erythrocytes to HeLa cells. *b*, Massive adhesion of neuraminidase treated erythrocytes, which have acquired a glycolipid (ceramide-tetraoside, *L* in Table 1) in their plasma membranes. Erythrocytes were incubated with 10 μl of ceramide-tetraoside in 100 μl of the incubation mixture for 45 min. Other methods as Fig. 2.

such as ganglioside or phosphatidyl inositol, did not adhere strongly. All the phospholipid particles tested adhered only moderately to HeLa cell monolayers. Nearly the same pattern of adhesion specificity with respect to the sugar moiety of glycolipids was obtained with BHK and MDCK cells. Adhesiveness of lipid particles to other cells was not rigorously quantitated.

To determine whether glycolipids could also promote adhesion between natural membranes, cells in which there was good correlation between adhesiveness and glycolipid content were required. Chick erythrocytes were satisfactory for this purpose, as they do not normally adhere to tissue culture cells but become artificially adhesive when glycolipids are incorporated into their membranes. The previously described method[16] for the incorporation of glycolipid into natural membranes was used. As shown in Fig. 2 adhesiveness of erythrocytes was enhanced on incubation with increasing lipid concentrations. Although the mechanism by which lipid is incorporated in this system is not known, we conclude from these results that lipids, especially glycolipids can promote the adhesion of natural membranes. Figure 3 demonstrates the difference in adhesiveness of glycolipid treated and untreated erythrocytes on HeLa cells. In a subsequent experiment all the lipids listed in Table 1 were incorporated into erythrocytes in identical conditions in order to determine their relative efficacy in enhancing adhesion of erythrocytes to tissue culture cells. Adhesion was measured by following the haemoglobin content which remained associated with the HeLa cells after washing. Results presented in Table 1 (right vertical column) correlated favourably with those obtained with lipid particles (left vertical column); that is, glycolipids containing at least four sugar molecules and a terminal galactose stimulated the adhesiveness of erythrocytes most. Comparable results were obtained from two independent experiments, so the values in Table 1 seem to represent the real relative adhesiveness of different lipids. Because of these results it also seems unlikely that the values shown for the glycolipid-coated erythrocytes reflected differential equilibrium in the binding of glycolipids to erythrocytes.

Glycolipids are specific components of plasma membranes[19]. It is known that animal cells contain a mixture of glycolipids, some of which terminate with a galactose molecule[20]. In the past, glycolipids have been considered to possess biological properties such as blood group specificity[20] or receptor functions[21,22], implying that they may be accessible to external factors. The present experiments have demonstrated a possible function of glycolipids in cell adhesion, an important property for the organisation of multicellular organisms.

A, Isolated from a Gaucher spleen[23]. *B*, Isolated from human brain[24]. *C*, Isolated from human brain[24]. *D–H*, Chemically synthesised by coupling ceramide with fucose, lactose, trigalactoside, tetragalactoside and tetraglucoside, respectively. Ceramide was obtained from brain cerebroside by the method of Carter *et al.*[25]. L-Fucose and lactose were from Serva. Trigalactoside and tetragalactoside were obtained from gum arabic (Serva) by partial hydrolysis with 0.2 M HCl at 100° C for 2 h and isolation from a column of active charcoal[26]. Tetraglucose was obtained from potato starch by the same procedure. Coupling of ceramide with oligosaccharides was performed via acetobromo derivatives of oligosaccharides with silver oxide as catalyst[27]. By this procedure the oligosaccharides were exclusively linked to the C-1 of ceramide. The yields of glycolipids were in general 3–10% of the theoretical value. The products were purified by silicic acid chromatography using increasing concentrations of methanol in chloroform (10%, 25%, 50%), methanol and finally with 10% concentrated ammonia in methanol as eluting solvents. Fractions were monitored by thin layer chromatography using chloroform–methanol–water (65–35–8) as the developing solvent. *I*, Globoside, isolated from MDBK cell as the major glycolipid. *J*, Obtained by chemical coupling of ceramide with the corresponding tetrasaccharide isolated from human milk[28], using the same procedure as described for *D–H*. *K*, Ganglioside isolated from human brain[29]. *L*, Ceramide-tetraoside. Obtained from ganglioside (G_{D1a}) by repeated hydrolysis with 0.02 M HCl at 80° C. The liberated *N*-acetylneuraminic acid and the HCl were removed by dialysis. Lipid particles containing these glycolipids or phospholipids were prepared essentially as described elsewhere[15], except that ratio of the components of the particles were modified to glycolipid or phospholipid–cholesterol–triolein–dansylsphingosine 1.2.0 1:0.01. The technique of binding assay of lipid particles is described in the legend to Fig. 1. The extent of adhesiveness was measured by the fluorescence intensity of adhered lipid particles. To measure fluorescence, the washed monolayers were left with 3 ml of ethanol for 10 min at room temperature and the ethanol extracts were measured in a Perkin-Elmer fluorescence spectrophotometer. In the case of adhesion studies using erythrocytes, lipids were incorporated into erythrocyte membranes as described in Fig. 2 at 5 μg lipid per incubation mixture. The treated erythrocytes were then incubated with monolayers of HeLa cells as for Fig. 2. Adhesion was measured by the haemoglobin content of adhered erythrocytes. For this purpose, monolayers were scraped off the plates in 2 ml of phosphate-buffered saline (PBS). Haemoglobin was then liberated by repeated (3×) freezing and thawing. After centrifugation at 2,000*g* for 10 min the absorption of the clear supernatant was measured at 540 nm.

* Excitation at 340 nm and emission at 500 nm. All values were relative to that of compound *L* set at 100.

† Extinction at 540 nm.

5,6-Dihydroxyindole is a melanin precursor showing potent cytotoxicity

WE have previously suggested that factors which regulate the proliferation and pigmentation of Cloudman S-91 mouse melanoma cells share common biochemical pathways[1,2]. Our conclusion was based on the following observations: (1) most mutant cells selected for their ability to grow in culture medium containing melanocyte-stimulating hormone (MSH) show an altered ability to produce pigment[1], and (2) tyrosinase is activated in response to elevated levels of cyclic AMP in a reaction apparently mediated by a cyclic AMP-dependent protein kinase[3]. This same protein kinase has been implicated as a positive regulator in the proliferation of Cloudman cells[4]. In addition, we found that some precursors of melanin are cytotoxic and that cells actively producing melanin run the risk of self-destruction through a build-up of these precursors. We have previously shown that pigmented cells are killed as a result of exposure to excess tyrosine or dihydroxyphenylalanine (dopa) in the culture medium[2,5]. It has since been demonstrated that actively melanising cells release a cytotoxic agent into their culture medium[6]. Here we present further evidence for the cytotoxicity of melanin precursors and show that 5,6-dihydroxyindole is one of the toxic compounds in the melanin biosynthetic pathway.

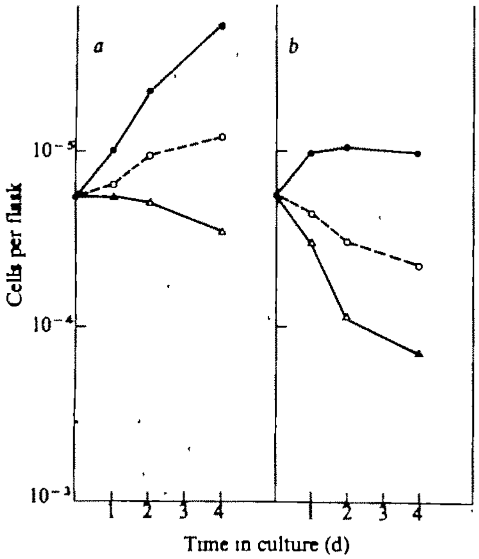

Fig. 1 Effects of dopa and MSH in combination with theophylline on cellular proliferation. Cells (2×10^4) were inoculated into Corning 25-cm^2 tissue culture flasks. The next day medium was removed and replaced with fresh medium containing no additions (●), 1×10^{-4} M dopa; (○), or 2.5×10^{-4} M dopa (△). *a*, Medium containing no MSH or theophylline. *b*, Medium containing MSH (2×10^{-7} M) and theophylline (5×10^{-4} M). At the times indicated cultures were collected in triplicate and counted in a Coulter counter. Variation within triplicates was less than ±20%. These experiments were repeated three times with similar results.

From various clinical and experimental observations it was concluded that during melanisation, pigment cells produce substances which are potentially autotoxic, and it was predicted that a strong stimulus for the synthesis of melanin would raise the intracellular concentration of tyrosine, dopa and their derivatives and increase the likelihood of self-destruction of the melanocytes[7-9]. This prediction was supported by results of studies with cultured mouse and hamster melanoma cells. Tyrosine, dopa and tryptophan were toxic to melanotic cells but not to amelanotic mouse L-cell fibroblasts, although dopa caused a slight retardation of the L-cell growth rate (Table 1). Other naturally occurring amino acids had little or no effect on either cell type. Cells with high tyrosinase activity that resulted from exposure to MSH were much more susceptible to the toxicity of melanin precursors than were cells not exposed to the hormone (Fig. 1 *a*, *b*). Treatment of cells with phenylthiourea, a potent and selective inhibitor of tyrosinase, provided complete protection from the toxicity of the melanin precursors[2]. Together, these results indicate that one or more products of the tyrosine–tyrosinase reaction are cytotoxic and that for cultured Cloudman S-91 melanoma cells, the earlier predictions[7] mentioned above are correct.

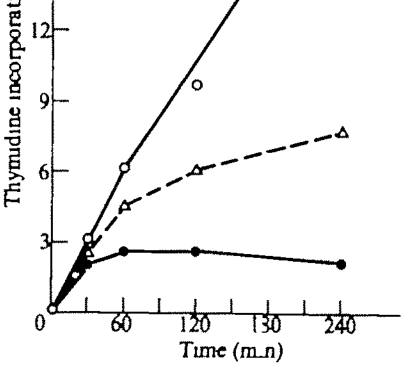
Table 1 Effects of various amino acids on the viability of melanoma cells

Additions to culture medium	Cell count (% of controls) after 6 d in culture	
	Melanoma cells	L cells
None	100	100
Ala, Arg, Asp, AspNH$_2$, Cys, Glu, GluNH$_2$, Gly, His, Ile, Leu, Lys, Met, Phe, Pro, Ser, Thr, Val	100	100
Dopa	<1	65
Tryptophan	1	100
Tyrosine	12	100

Mouse L cells or Cloudman S91 melanoma cells (2×10^4) were inoculated into 25-cm^2 Falcon tissue culture flasks in 4 ml F10 culture medium. The next day the cells were fed media supplemented individually with each amino acid indicated. All concentrations of amino acids were 5×10^{-3} M except dopa (1×10^{-4} M). Media were changed every 2 d and on the 6th day the cells were collected and counted in a Coulter counter. Control cultures of L cells had a generation time of 22 h, and control cultures of melanoma cells had a generation time of 43 h. These experiments were repeated twice, with similar results each time.

We next attempted to determine the nature of the compounds responsible for the cytotoxicity. Cultured cells were exposed for

Fig. 2 Effects of dopa and 5,6-dihydroxyindole on the rate of thymidine incorporation into acid-precipitable material. Cells were inoculated into Linbro wells as described in Table 2. At the times indicated the amount of ^{3}H-thymidine incorporation into acid-precipitable material was determined in quadruplicate wells. Variation was less than ±15%. The experiments were repeated twice, with similar results each time. ○ Controls; △, dopa (1×10^{-4} M); ●, 5,6-dihydroxyindole (1×10^{-4} M).



a few hours to various agents and their effects on the incorporation of ^{3}H-thymidine into acid-precipitable material were determined. In the first experiments cells were exposed to dopa (4×10^{-4} M) in the presence or absence of ascorbic acid (1×10^{-3} M) as a reducing agent[10]. After 16 h, cells in medium containing dopa alone were highly melanised and many were lysed. The culture medium was dark, and thymidine incorporation into acid-precipitable material was reduced to background levels (Table 2). In contrast, cells exposed to both dopa and ascorbic acid had the same morphology as control cells and the culture medium was clear. Thymidine incorporation was depressed in cells exposed to both dopa and ascorbic acid but it was significantly above background levels. Cells exposed to ascorbic acid alone appeared normal and the culture medium was clear, even though ascorbic acid reduced thymidine incorporation by about 33%. In a parallel experiment, cells were exposed to synthetic melanin (0.1 mg ml^{-1}) for 16 h. Melanin had no effect on cellular morphology and thymidine incorporation by cultures exposed to melanin was the same as that of control cultures (Table 2). Although these data do not rule out the possibility that dopa exhibited some inherent toxicity, our simplest interpretation of the results presented in Table 2 was that ascorbic acid, as long as it was present in the medium, reduced dopa quinone back to dopa and that the toxic effects were not due to dopa *per se* but rather to a compound(s) formed after dopa oxidation. As melanin itself was not toxic it seemed likely that the results were due to substances appearing after the oxidation of dopa but before the formation of melanin.

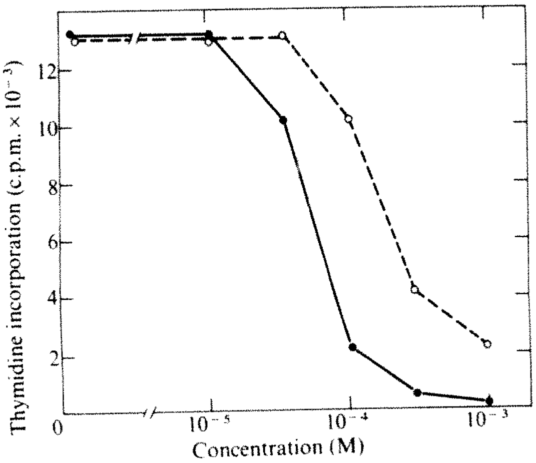
Table 2 Effects of dopa, ascorbic acid and melanin on thymidine incorporation by Cloudman S-91 cells

Additions to culture medium	^{3}H-Thymidine incorporation (c.p.m. per 10^5 cells per h)
None	1,694
Dopa	83
Dopa + ascorbic acid	605
Ascorbic acid	1,209
Melanin	1,630

Cells (10^5) were inoculated into Linbro multi-dish Disposo trays (2-cm^2 wells). After the cells had attached to the surface, medium was removed and fresh medium was added containing methyl-^{3}H-thymidine (0.3 Ci m mol^{-1}), dopa (4×10^{-4} M), ascorbic acid (1×10^{-3} M) and melanin (0.1 mg ml^{-1}, Sigma) as indicated. After 16 h the amount of ^{3}H-thymidine incorporated into acid-precipitable material was determined by the following procedure. Cells were removed from the wells with EDTA (1 mM) in Ca-Mg free Tyrode salt solution, centrifuged (2,000*g*, 5 min), resuspended in NaCl (156 mM) and precipitated with an equal volume of ice-cold trichloroacetic acid (10%, containing 1 mg ml^{-1} non-radioactive thymidine). After 15 min at 4°C the acid precipitates were filtered onto 0.45-μm Millipore filters and washed with 30 ml ice-cold trichloroacetic acid (5%, containing 1 mg ml^{-1} non-radioactive thymidine). The filters were dried in air and counted in a liquid scintillation counter. Counts represent the average from 4 separate cultures and the variation was less than ± 15%. These experiments were repeated three times, with similar results each time.

To test this interpretation, we examined the effects of 5,6-dihydroxyindole on cellular morphology and thymidine incorporation. This compound was chosen because of its ease of synthesis[11] and because it is only one step removed from melanin in the synthetic pathway. Cells were exposed to dopa (2×10^{-4} M) or 5,6-dihydroxyindole (2×10^{-4} M) simultaneously with ^{3}H-thymidine, and we found that the latter was considerably more effective than dopa in reducing the rate of thymidine incorporation into acid-precipitable material (Fig. 2). After 4 h, cells exposed to 5,6-dihydroxyindole were lysed and the culture medium was dark. In contrast, cells exposed to dopa for 4 h were not different from controls. Mouse L fibroblasts were also killed by 5,6-dihydroxyindole, indicating that this compound, in contrast to tyrosine, dopa and tryptophan, is not selectively toxic to pigment cells. A dose–response curve was constructed by comparing the effects of various concentrations of dopa and 5,6-dihydroxyindole on ^{3}H-thymidine incorporation (Fig. 3). About five times more dopa than 5,6-dihydroxyindole was required to achieve a 50% reduction in the incorporation of thymidine. These results suggest that 5,6-dihydroxyindole is at least one of the melanin precursors responsible for the cytotoxic effects observed after the oxidation of tyrosine and dopa by tyrosinase.

Fig. 3 Effects of various concentrations of dopa and 5,6-hydroxyindole on thymidine incorporation into acid-precipitable material. Cells were inoculated into Linbro wells as described in Table 2. Dopa (○) and 5,6-dihydroxyindole (●) were added at the concentrations indicated. After 4 h the amount of ^{3}H-thymidine incorporation into acid-precipitable material was determined in quadruplicate wells. Variation was less than ± 15%. The experiments were repeated three times, with similar results each time.



We have demonstrated that the generation of toxic products during melanogenesis is a characteristic unique to pigment cells, because tyrosinase is a gene product of these cells. Thus, tyrosine and dopa are specifically toxic to cells possessing tyrosinase activity whereas 5,6-dihydroxyindole shows a wider range of toxicity and is not specific to pigment cells. We hoped to develop these findings into a rationale for the chemotherapy of human melanoma. It is possible, however, that normal melanocytes have a protective mechanism against the toxicity of melanin precursors, as highly melanised but healthy cells are present throughout the animal kingdom and can also survive in culture for a considerable time[12]. Our present goals therefore, are to identify any protective mechanism(s) involved and to understand more about the factors regulating tyrosinase activity during melanogenesis.

Do radiation-induced thioguanine-resistant mutants of cultured mammalian cells arise by HGPRT gene mutation or X-chromosome rearrangement?

RESISTANCE to the cytotoxic purine analogue 6-thioguanine (TG) in cultured mammalian cells is known to be associated with deficiency in the X-chromosome-linked purine-salvage enzyme, hypoxanthine-guanine phosphoribosyl transferase (HGPRT, EC 2.4.2.8). The induction of mutations to TG resistance in cultured mammalian cells has been used to quantify the mutagenic effects of various physical and chemical agents[1-3] and it has been argued that such mutations arise primarily as a result of true gene mutations[4]. However, because ionising radiation induces TG-resistant mutants with very low HGPRT activity[5] and fails to induce the ouabain-resistance phenotype in mammalian cells[6,7], it has been suggested that ionising radiation leads to gross genetic damage rather than to point mutations in structural genes[2,7]. Here we present evidence that gross structural changes involving the X chromosome are the genetic basis of a significant proportion of radiation-induced mutation to TG resistance in cultured human fibroblasts.

If radiation-induced mutation to TG resistance (HGPRT-deficiency) arises in cultured human fibroblasts as a consequence of gross changes to the organisation of DNA, a proportion of the more extreme changes may be visible as aberrations in the X-chromosome region containing the HGPRT locus. Gene mapping experiments have assigned the HGPRT locus in man to the terminal region of the long (q) arm of the X chromosome[8] and using chromosome banding techniques we examined the complete karyotypes of radiation-induced TG-resistant mutants of cultured human fibroblasts so as to determine whether X-chromosome changes correlated with HGPRT deficiency.

Aberrations (exchanges and deletions) consistent with the mapped position of the HGPRT locus were apparent in the X chromosome of up to 40% TG-resistant mutants induced by various ionising radiations. Figure 1*a* is a summary of the pattern disruption points (PDPs) determined for 23 mutants induced by 250-kV X rays, carbon ultrasoft X rays, helium ions of 90 keV μm^{-1}, α particles from plutonium ($\sim$140 keV μm^{-1}) and nitrogen ions of 470 keV μm^{-1}. In the case of exchange aberrations the independence of the mutants described is clear, as all the exchanges were different. The majority of mutants with X-chromosome deletions were detected in a single experiment using nitrogen ion irradiations, and it is possible that two examples of del (X) (q26) were repeats of a single clone. With a single exception (an Xp exchange probably not associated with the mutant phenotype) all PDPs occurred in the q arm of the chromosome; from the clustering of exchange PDPs in the terminal region it may be concluded (bearing in mind the inherent 3-band uncertainty of PDP allocation[9]) that the locus determining the mutant phenotype is situated distal to Xq 22. This observation agrees with most other data on the chromosomal position of the HGPRT locus in man.

A direct association between induced TG resistance and X-chromosomal aberrations would require that such aberrations in non-mutant cells surviving the radiation should be rare. In agreement with this, we failed to detect aberrations in the X chromosomes of 25 non-mutant viable clones surviving the same dose of α particles as that used to induce the mutants. On the other hand, because the wild-type culture was of female origin the aberrations detected could be in the inactive X and unassociated with the mutant phenotype. We have not rigorously excluded this possibility, but in the case of two X-chromosome exchanges (mutants III and IV of Fig. 1*b*) the aberrant X chromosome completed localised DNA synthesis before the normal X (Fig. 2). Late replication is normally associated with the inactive X and hence we conclude that in these mutants the aberrant X was the active species and was probably responsible for the mutant phenotype. Finally, it should be pointed out that techniques of mutant selection do not exclude the possibility that some mutants with X aberrations might have arisen spontaneously during post-irradiation culture. However, examination of 20 spontaneous mutant

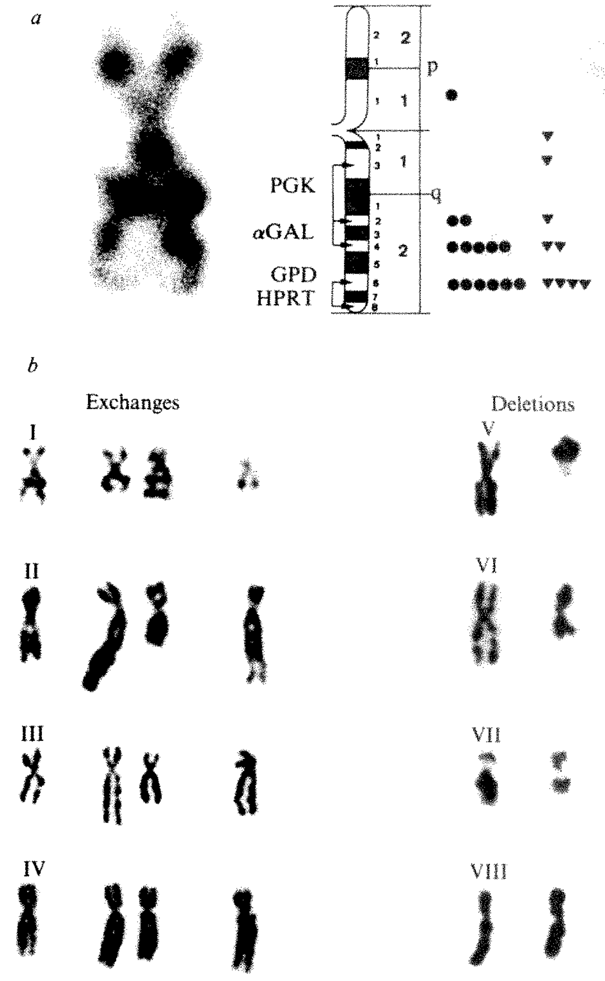

Fig. 1 *a*, Normal and schematic G-banded human X chromosome showing pattern disruption points detected in aberrant X chromosomes of a variety of thioguanine-resistant mutants of cultured fibroblasts induced by ionising radiations. ●, Exchange points; ▼, deletion points. Approximate positions for gene loci of PGK (phosphoglycerate kinase), α GAL (α galactosidase), GPD (glucose-6-phosphate dehydrogenase) and HGPRT (hypoxanthine-guanine phosphoribosyl transferase) are indicated. *b*, Examples of normal and derivative chromosomes from eight representative mutants (all 46 XX) induced by ionising radiations. Exchanges (I–IV): normal X chromosomes to the left, normal autosome to the right, derivative chromosomes central. I, t(X: 17) (q 24; q 25), mutant induced by carbon ultrasoft X rays; II, t(X; 5) (q 26; q 13), mutant induced by 250-kV X rays; III, t(X; 5) (q 24; q 13) and IV, t(X; 4) (q 26; q 31), mutants induced by α particles from plutonium. Deletions (V–VIII): normal X chromosomes to the left, deleted X to the right. V, del (x) (q 11); VI, del (X) (q 26), mutants induced by nitrogen ions of LET 470 keV μm^{-1}; VII, del (X) (q 24), mutant induced by α particles from plutonium. (Nomenclature according to Paris Conference[14]). Mutants were selected as being resistant to 3 μg ml^{-1} TG 7 d after radiation doses giving surviving fractions of 0.2 (refs [illegible], 15). All mutants were karyotyped using the ASG method[16]. The majority (including I, II and V–VIII) were karyotyped immediately after dissociation of selected mutant clones. This was a destructive technique and did not allow further study of these mutants. Six mutants induced independently by α particles were isolated and cultured before karyotyping; of these, three (III, IV and one other) showed unequivocal X-chromosome aberrations.

0028-0836/78/0276—0629$01.00

karyotypes failed to reveal any structural abnormalities in the X chromosomes, so such events are too rare to account for the numbers we have observed in irradiated cultures.

The conclusion that structural changes to the X chromosome result in the loss of HGPRT raises the question of whether the function of other Xq genes are also affected. As a preliminary test of this we examined the activity of glucose-6-phosphate dehydrogenase (GPD, EC1.1.1.49) using a semi-quantitative histochemical staining technique[10]. As judged by staining intensity, the variations in GPD activity among α-particle-induced TG-resistant clones was considerably greater than that observed among non-mutant surviving clones, with up to 5% of mutant clones showing very low activity and a similar number showing super-activity. In electrophoretic enzyme assays (Fig. 3) two karyotypically defined Xq exchange mutants were completely lacking in HGPRT but were not obviously deficient or super-active in GPD. However, because almost all mutant clones showing atypical GPD activity in histochemical assays showed very poor growth it has not yet been possible to carry out truly representative karyotypic and electrophoretic analyses, and hence the question of multiple gene effects in radiation-induced mutants remains unanswered.

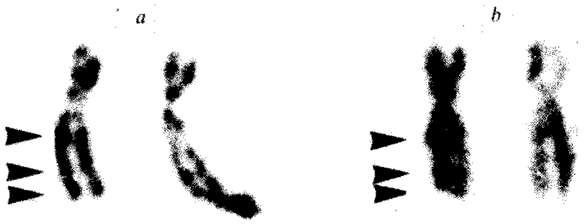

Fig. 2 Late replication of normal X-chromosome regions in two ♀ TG-resistant mutants with X-chromosome aberrations. *a*, Mutant III of Fig. 1*b*; *b*, mutant IV of Fig. 1*b*. For each chromosome pair the normal X is to the left. Late replicating regions of chromosomes were detected using the 5-bromodeoxyuridine (BUdR)–thymidine–33258 Hoechst method of Grzeschnik, Kim and Johannsman[17] with the modification that Jenner stain was used in place of Giesma. With this method late replication of a chromosome region is characterised by dark staining (indicated by arrows); early replicating regions (which incorporate BUdR into DNA) show lighter staining because the reaction of 33258 Hoechst with BUdR-substituted DNA causes that DNA to bind less Giesma or Jenner stain. The lighter staining of the q bands of the aberrant X chromosomes indicate that they were replicated early in the cell cycle.

From the karyotypic analysis presented in Fig. 1*b* it is possible to explain the TG-resistance phenotypes of radiation-induced mutants without invoking structural gene mutations. In the case of the deletion mutants (Fig. 1*b*, V–VIII), TG resistance probably arises by complete loss of the HGPRT gene from the karyotype in the acentric fragment which resulted from an incomplete radiation-induced structural aberration. For the exchange mutants (Fig. 1*b*, I–IV), loss of HGPRT could result from gene inactivation as a consequence of position effect[12] or, alternatively, the apparently simple reciprocal exchange configuration observed in mutants many generations after induction may be the stable manifestation of a more complex initial exchange event resulting in the loss of the HGPRT gene in a small interstitial chromosome deletion. The relatively poor resolution obtained with karyotypic analysis means that many small Xq changes will be undetected. It is therefore possible that the majority of radiation-induced TG-resistant mutants of cultured human fibroblasts arise by a process involving changes in chromosome structure rather than by true gene mutation. These conclusions on the nature of radiation-induced mutations in cultured mammalian somatic cells agree generally with *in vivo* observations on radiation-induced mutations in mouse germinal cells, many of which show phenotypic characteristics consistent with chromosomal changes[13].

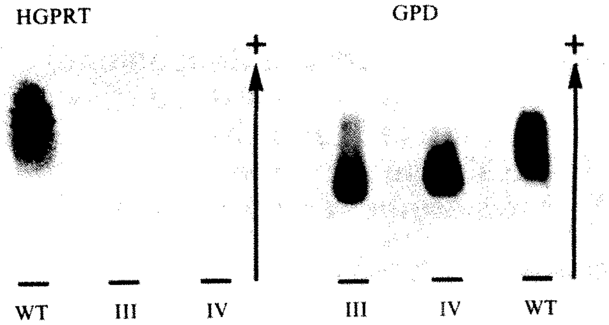

Fig. 3 Cellulose acetate gel electrophoresis of hypoxanthine-guanine phosphoribosyl transferase (HGPRT) and glucose-6-phosphate dehydrogenase (GPD) in extracts of wild-type and TG-resistant mutants of cultured human fibroblasts. WT, wild type; III and IV refer to the exchange mutants of Fig. 1*b*. Cells (2×10^6) washed twice with isotonic salts solution were lysed for 15 min at 0 °C in 0·1 ml Tris–HCl buffer (50 mM), *p*H 8.0, 0.1% Triton. Cell debris was sedimented by centrifugation at 1,000 r.p.m. for 10 min at 0 °C; 5-μl samples of the supernatant were used for each enzyme determination. Cellulose acetate gel plates (60 × 75 mm), applicators and electrophoresis chambers were all Zip Zone (Helena). The methods were as follows. HGPRT: electrophoretic buffer, Tris–citrate (15 mM), *p*H 7.6; separation at 200 V for 45 min with ice cooling. Reaction mixture: Tris–HCl buffer (50 mM), *p*H 7.4, 2.0 ml; ^{14}C-hypoxanthine (25 μCi ml^{-1}), 0.3 ml; $MgCl_2$ (0.25 M), 0.4 ml; phosphoribosyl pyrophosphate (0.01 M), 0.3 ml. A DEAE paper overlay method with subsequent autoradiography[18] was used to determine the location of the ^{14}C reaction product (inosine mnophosphate). GPD: electrophoretic buffer, Tris-glycine, *p*H 8.5 (3.0 g Tris, 14.4 g glycine w/w per l); separation at 200 V for 40 min with ice cooling and 2 μg NADP added to the sample to stabilise GPD. Reaction mixture: Tris–HCl buffer (50 mM), *p*H 8.0, 1.0 ml; $MgCl_2$ (0.25 M), 0.1 ml; NADP (1 mg ml^{-1}), 1.0 ml; phenazine methosulphate (2.5 mg ml^{-1}), 0.1 ml; monotetrazolium (10 mg ml^{-1}), 0.1 ml; glucose-6-phosphate (0.5 M), 0.2 ml. The staining procedure was to mix the reaction solution with 2 ml molten aqueous agarose (1.4%) at 60 °C and then pipette over the gel plate. The tetrazolium reaction was allowed to proceed for 20 min at 37 °C in darkness, after which the agar was washed from the plate and the plate subsequently washed and dried.

We thank J.R.K. Savage, T.R.L. Bigger and R. Holmes for practical advice with experiments, all our colleagues for comments on the work and the staffs of the AERE accelerators, Harwell for their cooperation.

Competition of normal β chains and sickle haemoglobin β chains for α chains as a post-translational control mechanism

ADULT human haemoglobin (HbA) is a tetrameric protein with two α and two β polypeptide chains. Theoretically, individuals heterozygous for a β-chain mutation should have equal amounts of the normal HbA ($\alpha_2^A\beta_2^A$) and an abnormal variant ($\alpha_2^A\beta_2^X$) in their red cells. However, these people usually have different amounts of the two haemoglobins. For example, the red cells of sickle cell trait individuals usually contain about 60% HbA and 40% HbS[1-5]. Those who also have an α-thalassaemia gene(s), which decreases production of α chains, have an even lower proportion of HbS[6-12]. Each of these two haemoglobin polymers has an α-chain type common to both proteins as well as a specific β^A or β^S chain type. The individual α, β^A, and β^S chain types can be isolated *in vitro* in a functional form so that the haemoglobin tetramers can be reconstituted from appropriate mixtures of α and β chains[13]. Here we report that more HbA than HbS was formed when a mixture of equal amounts of β^A and β^S chains was incubated with limiting concentrations of α chains. These results suggest that a similar form of post-translational control of haemoglobin assembly may exist in some erythroid cells *in vivo*. The accomplishment of these experiments and the interpretation of the results were greatly facilitated by the use of radiolabelled haemoglobin chains of high specific activity.

Red blood cells were obtained from a normal human adult and from an individual with sickle cell anaemia. The sickle blood cells were incubated with ^{14}C-leucine in a mixture supporting protein synthesis[14], to provide a source of ^{14}C-labelled β^S chains. Haemolysates of both normal and sickle cells were treated with *p*-chloromercuribenzoate, which reacts covalently with protein sulphhydryl groups, to dissociate the haemoglobins into the haem-containing subunit α and β chains[13]. The β^A chains were isolated from the normal haemolysate by the procedure of Geraci *et al.*[15], and the ^{14}C-labelled β^S chains were isolated from the sickle haemolysate by the modification of McDonald and Noble[16] using a column of DEAE–Sephadex A50. α Chains were prepared with a ^{3}H label so that the relative amounts of HbA and HbS formed in the reaction with β chains could be measured quantitatively. To provide α chains of high specific radioactivity, blood reticulocytes with unusually high haemoglobin synthetic activity were obtained from an individual with Hb Sabine, a β-chain variant, and were incubated with ^{3}H-leucine[17]. The Hb Sabine was isolated from the haemolysate by electrophoresis in columns of polyacrylamide gel, and normal, ^{3}H-labelled α chains were prepared from the abnormal haemoglobin by the method of Geraci *et al.*[15].

To form haemoglobin tetramers in physiological conditions, it was necessary for the isolated α and β chains to be entirely free of mercuribenzoate. This was accomplished by treatment of the mercurated chains with mercaptoethanol to regenerate the sulphhydryl groups, as described elsewhere[15,16]. We found less than 0.01 mol of Hg for each mol of chain when our preparations were analysed for the presence of residual Hg by atomic absorption spectrophotometry. All isolated chains were dialysed against 0.01 M potassium phosphate, *p*H 7.0, and stored at 4 °C under an atmosphere of carbon monoxide.

Various amounts of ^{3}H-labelled α chains were added to replicate mixtures containing excess, but equal, amounts of β^A and ^{14}C-labelled β^S chains. The reaction mixtures were incubated at 4 °C for 60 min, sufficient time for the isolated α and β chains to react completely and form Hbs A and S. The haemoglobin products and excess chain reactants were separated by electrophoresis of a sample of each reaction mixture on a strip of cellulose acetate. The distribution of ^{3}H radioactivity among the various protein components was determined by analysis of sections of the strip in a liquid scintillation system[14].

Figure 1 shows the results from a reaction in which the total concentration of β chains was eight times greater than that of α chains. About 40% of the total ^{3}H radioactivity migrated as HbS whereas 60% migrated as HbA. These data indicate that more α chains reacted with β^A chains to form HbA than with β^S chains to form HbS. In a control experiment, unreacted free α chains migrated in this electrophoretic system near the line of application at a position well separated from the haemoglobin tetramers (data not shown). The use of ^{3}H-labelled α chains allowed the precise detection of small amounts of haemoglobin products in the presence of excess β chains. Most of the ^{14}C-labelled β^S chains migrated slightly anodal to HbA in a position characteristic of unreacted β^S chains. As expected, a small fraction (about 10%) of the ^{14}C-labelled β^S chains migrated as HbS (Fig. 1). The high (>90%) recovery of β^S chain ^{14}C radioactivity in these two components eliminates selective instability or loss of β^S chains as explanations for the formation of less HbS than HbA.

Figure 2 shows the results from several reactions in which various concentrations of α and β chains were used. In each experiment, the initial amount of β^A chains was equal to that of ^{14}C-labelled β^S chains. The amount of HbS formed was less than that of HbA in all experiments in which α chains were present in limiting amounts (α/total β ratio<1). In these experiments, essentially all the ^{3}H-labelled α chains reacted to form HbA or HbS. Conversely, when α chains were present in an amount equal to or greater than that of total β chains, the amount of HbS formed was similar to that of HbA. More than 90% of the available ^{3}H-labelled α chains reacted to form Hbs S and A when the initial concentration of α chains was identical to that of total β chains. As expected, about half (47%) the ^{3}H-labelled α chains reacted to form the two haemoglobins in equal amounts when the initial concentration of α chains was twice that of total β chains. These results indicate that essentially all the β^A and β^S chains were able to combine with the complementary α chains in the reaction mixtures. Thus, our observation of a decreased production of HbS with limiting concentrations of α chains cannot be due merely to the existence of a fraction of β^S chains unable to react with the α chains.

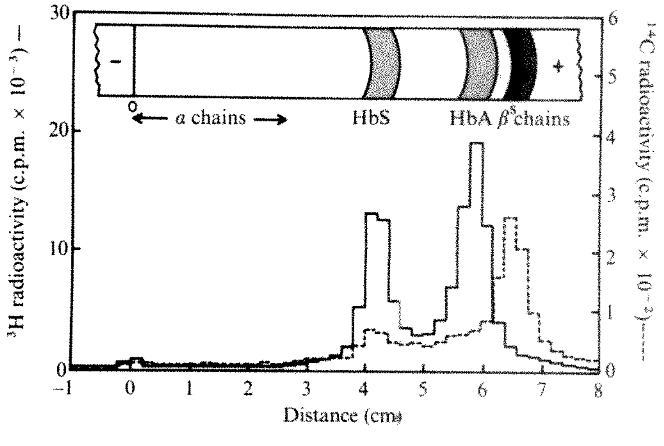

Fig. 1 Pattern of protein radioactivity after electrophoresis of a reaction mixture of α, β^A, and β^S chains. The mixture had 62 µg of ^{3}H-labelled α chains and 246 µg each of β^A and ^{14}C-labelled β^S chains in a total volume of 0.040 ml of 0.01 M potassium phosphate, *p*H 7.0. After incubation for 60 min at 4 °C, a sample of 5 µl of the reaction mixture was applied to a cellulose acetate strip. The electrophoresis was done, and the strip was cut into sections for radioactivity analysis, as described previously[14]. The positions of the stained bands of product haemoglobins and residual reactant chains are indicated at the top of the figure, and the line of sample application is denoted by zero. The β^A chains migrated off the anodal end of the strip during the electrophoresis. Almost 100% of the ^{3}H- and 91% of the ^{14}C-radioactivities applied to the strip were recovered in the sections.

0028–0836/78/0276—0631$01.00

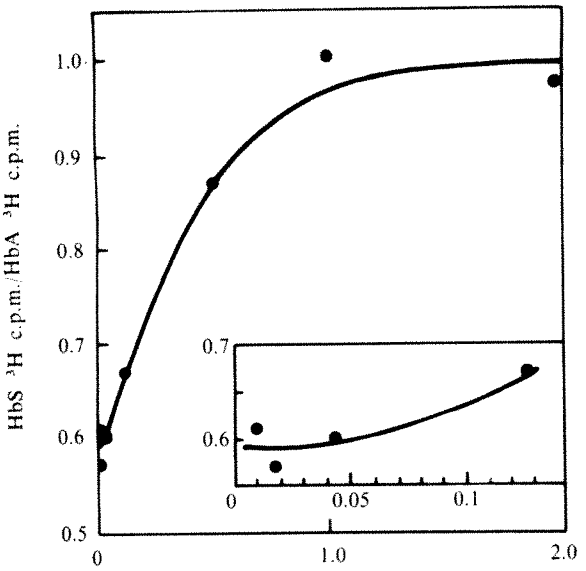

Fig. 2 Comparison of product haemoglobin radioactivities with the relative, initial concentrations of reactant chains for several experiments similar to that described in the legend to Fig. 1. The HbS/HbA ^{3}H-radioactivity ratio represents the relative amounts of ^{3}H radioactivity detected in the two haemoglobins after electrophoresis. The $\alpha/(\beta^A+\beta^S)$ chain ratio represents the relative initial amounts of α and total β chains. The inset shows the results from four experiments in greater detail. There were initially 246 µg each of β^A and β^S chains in these four reaction mixtures, with $\alpha/(\beta^A+\beta^S)$ chain ratios <0.2. The three reaction mixtures with $\alpha/(\beta^A+\beta^S)$ chain ratios of 0.5, 1.0 and 2.0 had initially 49, 25 and 12.5 µg, respectively, of each type of β chain in a total volume of 0.040 ml.

The ratio of HbS to HbA formed in these reactions fell with decreasing initial relative α-chain concentration (Fig. 2). However, when the relative α-chain concentration was sufficiently low (α/ total β ratio <0.05), the ratio of formation of HbS to HbA remained constant at about 0.6 (Fig. 2, inset). These HbS/HbA ratios represent amounts detected after complete reaction of the reagent chains during the 60-min incubation period. Although these were equilibrium measurements, the limiting value of about 0.6 for this ratio probably reflects the rates at which individual β^S and β^A chains reacted with α chains. When the α-chain concentration was increased, the resulting HbS/HbA ratio went from 0.6 to unity, as enough α chains were now available to combine with both β^S and β^A chains.

The β-chain monomer is probably the molecular species which reacts with α chains. As implied above, the difference in amounts of HbS and HbA formed in these studies probably occurs because of a difference in the relative affinities of β^S and β^A chain monomers for α chains. However, the following alternative explanation for our results remains to be eliminated. β Chains prepared by methods similar to those used in the present work exist almost exclusively in the tetrameric form, even at concentrations 50-fold lower than those used in our experiments[18-23]. The difference in amounts of HbS and HbA formed could conceivably be caused by a difference in the initial concentrations of β^S and β^A monomers resulting from unequal rates of dissociation of β_4^S and β_4^A tetramers rather than by a difference in affinities of β-chain monomers for α chains.

A similar difference in affinities of β^S and β^A chains for α chains was reported by Abraham and Huisman[24] and more recently by Lee *et al.*[25]. However, in their experiments, mercuribenzoate, added to cause tetramer dissociation during chain preparations, was still covalently bound to the subunits. Following mixture of the mercurated α and β chains, mercaptoethanol was added to aid the reconstitution of the haemoglobin tetramers by removal of the mercurial reagent. The direct addition of mercaptoethanol may result in the denaturation of a significant fraction of the chains. In our work, these denatured chains were removed during the preparative procedures. Moreover, we have found that, when partially mercurated chains are present in the reaction mixture, reconstitution of native haemoglobin is less efficient, and the tetramers formed migrate in a heterogeneous manner during electrophoresis. It is conceivable that the presence of the rather bulky mercury groups induces spurious recombination of α and β chains and influences the relative amounts of HbS and HbA observed. In the present work, the complete removal of the mercurial reagent before reaction of the chains ensured the reconstitution of haemoglobins in physiological conditions. Moreover, the use of ^{3}H- and ^{14}C-labelled chains enabled us to detect any chains partially damaged in preparation and therefore unable to form proper haemoglobins.

The results of our experiments suggest a type of post-translational control which may occur in the synthesis and assembly of HbA and HbS in some sickle trait erythroid precursor cells. Past studies have shown that the reticulocytes of sickle trait individuals who carry an α-thalassaemia gene have a lower rate of synthesis of α chains than of β chains[26,27]. These individuals also have an unusually low concentration of HbS (about 25–30% HbS, 70–75% HbA) in their red cells. A limiting concentration of newly synthesised α chains in the reticulocytes and other red cell precursors may contribute to the decreased concentration of HbS by a mechanism similar to that observed in these experiments. An analogous model has previously been proposed to explain the different concentrations of HbH and Hb Bart's observed in individuals with HbH disease[28,29], an α-thalassaemia disorder. Conversely, β-chain competition for α chains probably does not contribute to the difference in HbS and HbA levels in sickle trait individuals without an α-thalassaemia gene(s) and without the concomitant deficiency in reticulocyte α-chain synthesis[26,27].

We thank D.W. and C.W. for donations of sickle cell and Hb Sabine blood, respectively, and Dr Joel Moake for the use of his laboratory in the ^{3}H-labelling incubations. Transfer of the drug-resistance transposon Tn*5* to *Rhizobium*

TRANSPOSONS are discrete sequences of DNA that are incapable of self-replication and can insert into DNA replicons, such as chromosomes or plasmids, in the absence of the *recA* gene function[1]. Insertion can be random and where it occurs into the continuity of a gene leads to non-leaky polar mutations[1]. Some transposons carry drug resistance genes and thus insertions can be mapped as drug-resistance markers[1]. We report here that Tn*5*, a transposon coding for kanamycin resistance[2], can insert into the chromosome of *Rhizobium leguminosarum*, the bacterium responsible for nodulation and nitrogen fixation in *Pisum*, *Vicia*, *Lathyrus* and *Lens*.

P1 group R plasmids, such as RP4, are able to infect most Gram-negative bacteria[3,4] and have been valuable for establishing linkage maps for many species[5–8]. Transfer between *Escherichia coli* and *Rhizobium* usually occurs at a frequency of about 10^{-2} (ref. 5). Recently Boucher *et al.*[9] reported that when the lysogenic phage Mu was inserted into RP4 this frequency was reduced about 10^5-fold and the plasmids that were transferred were altered. Van Vliet *et al.*[10] have since shown that the same applies to transfers from *E. coli* to *Agrobacterium tumefaciens* and that those plasmids which do become established in this new host have large deletions of the Mu phage. Restriction and the functioning of at least one Mu gene (*r*23) are both involved in reducing the ability of these plasmids to become established[9,10]. Van Vliet *et al.*[10] also reported that the inability of RP4::Mu plasmids to become established in *A. tumefaciens* could be utilised to carry transposons into this species to obtain transposon mutagenesis. Tn*7* insertion and deletion mutations in *A. tumefaciens* plasmids have since been important in the genetic analysis of the role of such plasmids in tumour formation[11].

We attempted to use an RP4::Mu::Tn*7* plasmid (provided by Dr M. van Montagu, Gent) to obtain transposon mutagenesis in *R. leguminosarum*. Transfer of either the RP4 or Tn*7*-coded drug resistances from an *E. coli* donor could not be detected (frequency less than 10^{-8}) in crossing conditions in which the frequency of wild-type RP4 transfer was 10^{-2}. Although these crosses were unsatisfactory for introducing Tn*7* into *R. leguminosarum* they demonstrated that Mu insertions into RP4 could be used to prevent establishment of this plasmid in this host. Tn*5* (kanamycin) and Tn*10* (tetracycline) are probably the best studied transposons[1] and both are relatively nonspecific in their sites of integration into the *E. coli* chromosome[1]. As RP4 codes for resistance to both these antibiotics we constructed a new P1 plasmid carrying Mu (see footnote to Table 1), using a plasmid that coded only for gentamicin, spectinomycin and low-level streptomycin resistance (pPH1JI)[12]. A derivative of this plasmid carrying Mu and Tn*5*, called pJB4JI, was used as a carrier of Tn*5* into three *Rhizobium* species (Table 1). The data in Table 1 show that the ability of PJB4JI, to become established in these species was reduced relative to the parent plasmid pPH1JI. Bacteria resistant to kanamycin, kanamycin plus gentamicin and gentamicin alone were found in these crosses (Table 1). None of these was found to be able to transfer drug resistance to *E. coli* (frequency less than 10^{-8}) in conditions where pPH1JI transfer occurred at a frequency of approximately 10^{-2}.

To be useful as a generalised mutagen a transposon needs to be relatively nonspecific in its insertion. This was tested for Tn*5* by replica-plating kanamycin-resistant derivatives selected on complete medium to minimal medium and scoring for auxotrophy. For *R. leguminosarum*, *R. trifolii* and *R. phaseoli* the frequency of auxotrophy was about 0.3% (compared to a spontaneous rate of less than 10^{-8}) and the range of auxotrophs found suggests that insertion was random. Auxotrophic mutants with the following requirements have been found to date: for *R. leguminosarum*, leucine (2), adenine (5), serine (2), riboflavine (1), methionine (2), adenine or guanine (1), phenylalanine + tyrosine (1) and two with unknown requirements; for *R. trifolii*, tryptophan (2), adenine or guanine (1), leucine + isoleucine + valine (1); for *R. phaseoli*, phenylalanine (1), tryptophan (2), methionine (1), leucine (1), adenine (2), uracil (1), cysteine or methionine (2) and two with unknown requirements. These results indicate the potential for obtaining apparently random mutagenesis in *Rhizobium* species.

Because the vehicle for introducing Tn*5* into *Rhizobium* carried phage Mu, it is conceivable that the mutagenesis was

Table 1 Transfer of kanamycin (Km) and gentamicin (Ge) resistance from *Escherichia coli* to *Rhizobium* species*

Recipient	pPH1JI	Plasmid in donor† pPH1JI::Mu::Tn*5* (pJB4JI)		
	Ge	Ge	Km	Ge + Km
R. leguminosarum 726	10^{-2}	10^{-7}	10^{-6}	5×10^{-8}
R. trifolii 6709	10^{-1}	10^{-6}	5×10^{-6}	2×10^{-8}
R. phaseoli 1234	10^{-1}	10^{-6}	5×10^{-6}	1.5×10^{-8}

Crosses were performed as described by Beringer *et al.*[5] except that mating was allowed to proceed for only 4 h at 28 °C. The transfer of plasmids and resistance markers was selected on complete (TY)[5] medium supplemented with gentamicin (5 μg ml^{-1}), kanamycin (20 μg ml^{-1}), streptomycin (50 μg ml^{-1}) and rifampicin (20 μg ml^{-1}) as required. The transfer of gentamicin plus kanamycin resistance was determined by replica-plating colonies selected on a single antibiotic to medium containing the other. *R. leguminosarum* strain 726 is a rifampicin resistant derivative of our wild-type strain 300 (ref. 15). *R. trifolii* strain 6709 and *R. phaseoli* strain 1234 are streptomycin-resistant derivatives of strains 204 and 3644 from the Rothamsted Culture Collection. Plasmid pJB4JI was constructed in this laboratory by selecting Mu c^+ lysogens of an *E. coli* J53 strain (carrying the P1 group plasmid pPH1JI) after spotting Mu on to a lawn of log phase bacteria. Four lysogens were crossed to a Mu *cts* lysogen of *E. coli* (strain SB1801) with selection for gentamicin resistance carried on pPH1JI and growth at 42 °C. Gentamicin-resistant colonies growing at 42 °C were presumed to carry pPH1JI and the wild-type Mu which was required to suppress the thermoinducible Mu *cts* phage in strain SB1801. Ten clones were picked and regrown under these selective conditions before crossing with an *E. coli* J53 *nal* strain and separately with an *R. leguminosarum* recipient in patch matings as described by Johnston, Setchell and Beringer[16]. All 10 clones transferred gentamicin resistance and the ability to produce Mu phage to strain J53 *nal*; none transferred gentamicin resistance to the *R. leguminosarum* strain, though transfer of pPH1JI would have occurred. Each clone was assumed to carry Mu inserted into a part of the plasmid not carrying important transfer genes. One clone was crossed into an *E. coli* recipient (strain 1752) carrying a chromosomally inserted Tn*5*. The pPH1JI::Mu derivative of strain 1752 was crossed with a suitable *E. coli* recipient with selection for kanamycin transfer. Kanamycin-resistant transconjugants were crossed to a J53 *nal* recipient and a kanamycin and gentamicin-resistant derivative (strain 1830) was purified. Strain 1830 transferred both resistances at high frequency between *E. coli* strains and was found to be Mu immune but unable to produce viable Mu phage. This indicates that Tn*5* had inserted either into Mu or beside it, causing a deletion into Mu. The pPH1JI derivative plasmid carrying Mu and Tn*5* is called pJB4JI and the pPH1JI::Mu parent plasmid is called pJB9JI.

* Frequencies of transfer are approximate and measured per recipient plated.

† Donor was *E. coli* strain J53 *nal* carrying the plasmid shown.

Table 2 Transduction of Tn*5*-associated auxotrophs by rhizobiophages RL38 and RL39

a Selection for the transfer of kanamycin resistance

Donor*	Frequency of kanamycin resistance (per recipient)			Proportion of kanamycin resistant recipients also receiving Tn*5*-associated auxotrophy		
	RL38	RL39	Control	RL38	RL39	Control
T94	1×10^{-5}	1×10^{-6}	1×10^{-8}	100/100	95/95	0/4
T95	8×10^{-6}	1×10^{-6}	1×10^{-8}	95/95	64/64	0/1
T133	6×10^{-6}	9×10^{-7}	$<10^{-8}$	250/250	150/150	—

b Selection for the transfer of prototrophy

Recipient	Frequency of prototrophy (per recipient)			Proportion of prototrophic recipients also kanamycin sensitive		
	RL38	RL39	Control	RL38	RL39	Control
T94	2×10^{-5}	7×10^{-7}	$<10^{-8}$	100/100	100/100	—
T95	3×10^{-5}	2×10^{-6}	5×10^{-8}	292/292	249/251	3/7
T133	2×10^{-6}	3×10^{-7}	3×10^{-8}	544/545	284/284	10/10

* T94, 95 and 133 are derivatives of the *R. leguminosarum* strain 300 carrying respectively auxotrophic requirements for adenine, leucine and arginine + uracil (*pyrA*?) resulting from the transfer of Tn*5* from *E. coli*. Phages RL38 and RL39 have recently been isolated as lytic phages for *R. leguminosarum* strain 300 (A.V.B-W., in preparation). Transduction was essentially as described by Ely and Johnson[17] for *Caulobacter crescentus*. Phages were irradiated with ultraviolet light to 0.1% survival and added to the recipient at a multiplicity of infection of about one phage per bacterium. Suitably marked strains of *R. leguminosarum* were used in these crosses so that contamination of phage preparations by viable bacteria would have been detected in the analysis of recombinants.

associated with Mu insertions into the chromosome[13]. This is unlikely for a number of reasons.

(1) Van Vliet *et al.*[10] have reported that a major factor limiting the ability of RP4::Mu plasmids to become established in *A. tumefaciens* is likely to be the formation of extensive deletions in the plasmid, which do not occur in the absence of Mu. Those few plasmids that do become established have extensive deletions of Mu. Thus the inheritance of fully functional Mu genomes would appear to be unlikely.

(2) A direct association between kanamycin resistance and induced auxotrophy was demonstrated by transduction (Table 2) and conjugation (J.E.B. unpublished results). The data for transduction are particularly convincing as relatively small pieces of DNA are transferred. They show an almost complete correlation of auxotrophy with resistance, whether selection was made for prototrophy or for transfer of kanamycin resistance (Table 2).

(3) Twelve auxotrophic mutants arising from the transfer of Tn*5* were tested for reversion to prototrophy. For seven of these mutants, reversion to prototrophy was not detected (frequency less than 10^{-8}) and for two others, occasional colonies of presumptive revertants were detected (frequency about 10^{-8}). Three strains had reversion rates of about 10^{-8}, 10^{-5} and 10^{-6}, and respectively 10%, 34% and 90% of revertants were kanamycin sensitive. The genetic basis of the reversions observed was not determined, but it can be assumed that the kanamycin-sensitive revertants were not due to suppression but to a precise excision of the insertion which had caused the mutation. Spontaneous reversion of Mu-induced mutations in *E. coli* is exceedingly rare[13], which suggests that at least the reverting mutants were not Mu-induced, unless the precise excision of Mu from the *R. leguminosarum* chromosome is more frequent than from the chromosome of *E. coli*.

This work clearly shows that a plasmid carrying Mu can be used to introduce a transposon (Tn*5*) into three *Rhizobium* species. This transfer is associated with the formation of auxotrophic mutants in these species and has been used to provide a readily selectable phenotype for at least one indigenous plasmid in *Rhizobium*[14]. We cannot be certain, at present, that Mu is not involved, but this does not detract from the value of the technique for establishing mutagenesis by an easily mapped insertion 'mutagen'. This should be of particular value in studies of the *Rhizobium*–legume symiosis as the analysis of defective mutants of *Rhizobium* depends on plant tests. Thus the mapping of symbiotically-defective mutants obtained by 'conventional' means requires that each recombinant from a cross be tested individually on a plant. However transposon-induced mutations can be mapped by mapping the position of the drug resistance carried on the transposon. Therefore transposon-induced symbiotic mutations can theoretically be mapped using the minimum of plant tests, which are expensive and time consuming.

J.E.B. thanks Jeff Schell and Marc van Montagu for helpful discussion. We thank all those who provided phages and bacterial strains, and in particular Caludine Elmerich for suggesting the procedure for making the pPH1JI::Mu plasmid. We should also like to acknowledge the assistance of Wendy Smith and Shelagh Hoggan and the constructive comments of David Hopwood and Nick Brewin during the writing of the manuscript. J.L.B. was supported by an SRC CASE Award in conjunction with the Nickerson Seed Company. A.V.B-W. was supported by an ARC Studentship.

High frequency transfer of nodulating ability between strains and species of *Rhizobium*

THE most striking and important feature of members of the genus *Rhizobium* is their ability to nodulate and fix nitrogen in the roots of legumes. There is specificity in this interaction. Legumes belonging to one cross-inoculation group are nodulated only by certain classes of *Rhizobium* and indeed *Rhizobium* species are defined in terms of the host legumes that they can nodulate—for example, *R. leguminosarum* nodulates peas, *R. trifolii* nodulates clover and *R. phaseoli* nodulates beans of the genus *Phaseolus*. The genetic bases of the nodulation process and of host specificity are poorly understood. Many *Rhizobium* strains harbour plasmids[1–4] and genetic evidence has suggested that such plasmids might carry some of the information required for the development of the symbiosis[5,6]. We report here that the ability to nodulate peas can be transferred at high frequency from a strain of *R. leguminosarum* to a non-nodulating strain of *R. leguminosarum* and to three other species of *Rhizobium* that nodulate legumes other than peas. We infer from this that some of the genetic information required for nodulation is plasmid-linked.

In the previous paper[7] the insertion of the transposon Tn*5* (conferring kanamycin resistance) into the chromosome of strains of *Rhizobium* was described. Using the same method we attempted to insert Tn*5* into pRL1JI, a conjugative plasmid first found in an *R. leguminosarum* field isolate (strain 248). Strain 248 produces a bacteriocin and this ability can be transferred at high frequency ($\sim 10^{-2}$) to other strains of *Rhizobium*[8]. pRL1JI was transferred by conjugation into *R. leguminosarum* strain 1062 (*ura14 trp16 str69*), a derivative of strain 300 (ref. 9). One pRL1JI transconjugant, strain 2406, was used as a recipient in a cross with *Escherichia coli* strain 1830 that carries pJB4JI (ref. 7) (pPH1::Mu::Tn*5*) and selection was made for the transfer of kanamycin resistance. Resistant colonies arose at frequencies of $\sim 10^{-6}$ and 20 of them were used in patch crosses with *R. leguminosarum* and separately with *E. coli* recipients. None transferred kanamycin resistance to *E. coli* but one transferred it at very high frequencies to *R. leguminosarum*. This strain (T3) and a control that did not give kanamycin transfer in the patch crosses (T10), were each crossed with *E. coli* and *R. leguminosarum* using membrane crosses to determine frequencies of transfer. None transferred kanamycin resistance to *E. coli* (frequency $< 10^{-8}$). T3 and T10 transferred kanamycin resistance to the *R. leguminosarum* recipient at frequencies of about 10^{-2} and 10^{-8} per recipient, respectively. Recipients of kanamycin resistance from T10 may have arisen by the pick-up of Tn*5* onto a conjugative plasmid.

Strain T3 failed to produce the bacteriocin specified by pRL1JI; one possible explanation was that Tn*5* had been inserted into (or beside) the bacteriocin production gene. To test this hypothesis T3 was crossed with a strain of *R. leguminosarum* that did not produce the bacteriocin. One kanamycin-resistant transconjugant was purified and was used to propagate the transducing phage RL38 (A.V.B.-W., in preparation). The lysate was used to transduce a strain of *R. leguminosarum* that carried pRL1JI and hence produced bacteriocin. Kanamycin-resistant transductants arose at a frequency of $\sim 10^{-6}$ per recipient cell; 99.5% of them failed to produce bacteriocin, showing that kanamycin resistance was closely linked to the inability to produce bacteriocin and suggesting that Tn*5* had indeed inserted into pRL1JI and had caused tthe loss of production in strain T3.

Strain T3 was used as a donor in crosses with the strains in Table 1. In all cases kanamycin-resistant transconjugants arose at frequencies of $\sim 10^{-2}$. When each of the parental strains was plated separately on the selective media colonies occurred at frequencies of $\sim 10^{-8}$. From each cross several transconjugants as well as control clones of the recipient strain which had not acquired kanamycin resistance were used to inoculate peas.

The control clones nodulated peas rarely or not at all (Table 1). One plant inoculated with one clone of strain 6710 had a single small nodule. Such sporadic nodulation of peas by *R. trifolii* has been observed before[10]. In contrast, the transconjugants induced many nodules per plant, showing that the ability to nodulate peas could be transferred to a non-nodulating strain of *R. leguminosarum* and to other species of *Rhizobium*. Most of the *R. trifolii* and *R. phaseoli* transconjugants began to produce nodules about one week later than normal and the nodules were smaller than those found following inoculation of peas by *R. leguminosarum*. Strain 9009 is a slow-growing strain able to nodulate *Cicer*. The first appearance of nodules formed by transconjugants of this strain was delayed for a further 4–5 d and, in contrast to the other recipients, not all of them nodulated peas; two failed to do so. However all three plants inoculated by one of the *R. phaseoli* transconjugants had nodules that appeared at the normal time and were of similar size and number to those found following inoculation by *R. leguminosarum*.

The roots of a sample of the plants inoculated by transconjugants were tested for acetylene reduction as an assay for nitrogenase activity (Table 1). All the strain 6015 transconjugants were able to reduce acetylene, but the interspecific transconjugants varied in their ability to do so. All of the *R. phaseoli* transconjugants, but only a minority of those of the other two species, reduced acetylene and with a single exception the rates were low (~10% of those found following inoculation of peas by strains of *R. leguminosarum*) The exception was the *R. phaseoli* transconjugant that nodulated peas as well as the *R. leguminosarum* control; this reduced acetylene at normal rates. It is not clear why the ability to reduce acetylene varies both between the different recipient classes and between transconjugants of the same recipient. We cannot say whether the transconjugants which failed to reduce acetylene would have done so after prolonged growth of the plants, because in our conditions of growing peas the plants became distressed about five weeks after germination.

The *R. trifolii*, *R. phaseoli* and strain 9009 transconjugants were used to inoculate *Trifolium repens* (var. S100), *Phaseolus vulgaris* (var. Fino) and *Cicer arietinum* L. (var. G130) respectively, these being the normal hosts for the parents of these transconjugants. Chickpeas (*C. arietinum*) were inoculated and grown in the same way as peas; the methods used for beans and clover were essentially as have been described[9] except that clover seedlings were grown in vertically held Petri dishes (B. Rolfe, personal communication). All the interspecific transconjugants formed nodules on their original hosts but the nodules were slow to appear and were fewer and smaller than those induced by their respective parents on the same hosts. Interestingly, of the *R. phaseoli* transconjugants tested, the one that best nodulated peas was poorest on beans, inducing only a single ineffective nodule on a total of three inoculated plants.

The finding that the ability to nodulate peas was transferred from a strain of *R. leguminosarum* at high frequency is strong evidence that in this species there is a plasmid carrying genetic information required for nodulation. We cannot say whether this information is in the bacteriocinogenic plasmid pRL1JI or in another plasmid that was cotransferred at high frequency. T3

Table 1 Transfer of ability to nodulate peas and reduce acetylene in the nodules from strain T3 to other strains of *Rhizobium*

Recipient strain	Species	Markers	Control clones: No. nodulating/no. tested	Transconjugants clones: No. nodulating/no. tested	Transconjugants clones: No. reducing C_2H_2/no. tested
6015	*R. leguminosarum*	*phe1 trp12 rif +392 str37 inf*	0/9	17/17	8/8
6661	*R. trifolii*	*rif*	0/7	16/16	2/9
6710	*R. trifolii*	*rif*	1/10	17/17	1/8
1233	*R. phaseoli*	*rif*	0/6	9/9	9/9
9009	*R.* '*species*'		0/10	8/10	2/8

Strain 6015 is a non-nodulating derivative of strain 897 (ref. 14) isolated following ultraviolet treatment. In many previous studies it had never been shown to nodulate peas. Strains 6661, 6710 and 1233 are *rif* mutants of strains 12, 204 and 3644 respectively of the Rothamsted Culture Collection. Strain 9009 is strain 3889 from Rothamsted, it is a member of the cowpea miscellany. These last four strains were effective (that is, reduced acetylene) on their hosts respectively clover, clover, French bean and chickpea. Media and growth conditions for *Rhizobium*, and the pea inoculation tests have been described[15] as has the method of doing bacterial crosses[13]. The crosses were plated on minimal medium and where appropriate, rifampicin (20 μg ml^{-1}) to counterselect the donor plus kanamycin (20 μg ml^{-1}) to select transconjugants. Colonies were purified by streaking twice on the same selective medium and cultures were grown and used to inoculate two peas (var. Wisconsin Perfection). The plants were monitored for the appearance of nodules After 3–4 weeks the plants were scored for nodulation and the ability to reduce acetylene. Nodules from each of the peas nodulated by the transconjugants were excised, surface sterilised, crushed and the contents plated on complete medium. About 50 single colonies were replicated to appropriate selective media. In all cases the colonies had the appropriate markers.

was not a high-frequency donor of chromosomal markers in the cross between T3 and strain 6015 as, when selection was made for the transfer of *phe1*$^+$ or of *trp12*$^+$, progeny arose at frequencies of only $\sim 10^{-8}$. Thus nodulation ability was transferred at frequencies $\sim 10^6$-fold greater than these alleles.

Earlier studies showed that the plasmid R68.45 mediated chromosomal recombination between *R. leguminosarum*, *R. trifolii* and *R. phaseoli*[12]. The strains used were derived from the same parents as were strains 6015, 6661 and 1233 respectively. These studies have since been extended (A.W.B.J., unpublished observations). In separate crosses 16 different alleles were transferred from *R. trifolii* to *R. leguminosarum*. From each cross 20–30 recombinants were tested for their ability to nodulate clover but this was not co-inherited with any of the alleles tested. The location of the alleles chosen on the *R. leguminosarum* chromosome[13] was such that if any gene(s) for host specificity was chromosomally located and was transferred and expressed then we would have expected to have been able to map it. This negative result provided indirect evidence for plasmid involvement in host specificity.

Higashi[5] concluded that the ability to form infection threads on clover could be transferred by way of a plasmid from *R. trifolii* to *R. phaseoli*. He did not say whether the transconjugants could still nodulate their normal host. We do not know why, in our study, most interspecific transconjugants nodulated both peas and the host of the recipient, albeit with reduced efficiency in both cases. It is possible that the introduction of the plasmid did not replace the genetic information needed by the recipient strain to nodulate its normal host. Perhaps the presence in the same cell of genetic information needed to nodulate host plants of two different cross-inoculation groups causes it to be deficient in its nodulation of either. The single *R. phaseoli* transconjugant that nodulated peas well but beans barely at all may represent a case where the information needed to nodulate beans had been lost.

Physical isolation and characterisation of the plasmid(s) involved may help to clarify their role in symbiosis. Such analysis may be complex, as *R. leguminosarum* strain 300, the parent of the strains used in this study, contains three large ($MW > 10^8$) plasmids[16].

Dynamics of protein hydration by quasi-elastic neutron scattering

THE importance of water and its properties for biological systems makes the analysis of the dynamics of protein hydration of special interest[1–3]. It has long been recognised[2] that neutron scattering can, in principle, provide the most complete description of molecular motions in hydrated biopolymers. Here we report the first results of an application of high-resolution quasi-elastic neutron scattering[4–7] to the dynamics of protein hydration. A neutron beam incident on a biological sample produces scattered radiation that consists of a coherent part (that is, one that gives rise to an interference pattern which, in its Bragg scattering, contains the structural information[8–10]) and an incoherent part that cannot give interference effects but exhibits spectral changes which carry information on dynamic processes. Quasi-elastic neutron scattering explores the low-frequency region of the spectrum characterised by energy transfers of the order of, and less than, $1\ \text{cm}^{-1}$. Because of the very large incoherent scattering cross-section of protons (80 b) relative to all other nuclei (<0.4 b) present in natural biological samples, the incoherent scattering is almost entirely due to hydrogenous groups and water molecules. By replacing some or all of the carbon-bound hydrogens by deuterium (2 b), dynamic contrast factors of up to 15 can be attained so that a wide range of contrast experiments becomes possible.

In the case of hydrated biopolymers, there are three main classes of motions that may be investigated by incoherent neutron scattering: polypeptide side-chain motions[11], intramolecular modes involving subunits and larger segments of a macromolecule, and motions associated with the water of hydration. Recent theoretical work on protein dynamics has considered thermodynamic fluctuations[12], the fluid-like nature of thermal motions on a picosecond time scale[13], segmental flexibility[14] and folding[15], and computer simulations of the solvent structure[16]. In an effort to exploit the potential of recent advances in high-resolution neutron spectroscopy[6,17,18] in studies of this kind, we have examined the dynamics of water molecules interacting with a fully deuterated globular protein at low to moderate levels of hydration.

We used two biosynthetically fully deuterated samples of the multimeric chromoprotein C-phycocyanin (MW 190,000) extracted from *Synechococcus lividus*[19–21]. Blue–green algae contain large amounts of phycocyanin and are capable of synthesising it in extreme environmental conditions. Current interest in protio- and deuterio-phycocyanin relates primarily to its photochemical properties and to the opportunities it offers as a model system for studying the inter- and intramolecular forces involved in folding and aggregation processes. One sample consisted of stacks of protein films (surface density $\approx 5\ \text{mg cm}^{-2}$) cast on thin Al foils, the other was in the form of fluffy aggregates of wisp-like particles obtained by drying from aqueous solutions. The IN10 backscattering spectrometer[17] at the Institut Laue-Langevin, Grenoble, was used to record quasi-elastic spectra at 5 or 6 scattering angles between $2\theta = 9.8°$ and 110° (corresponding to momentum transfers $k = (4\pi/\lambda_0) \sin\theta = 0.17$ and $1.64\ \text{Å}^{-1}$) within a spectral window of 0.07 or $0.11\ \text{cm}^{-1}$ centred on the incident neutron wavelength $\lambda_0 = 6.27$ Å (Fig. 1). To obtain reliable and consistent values for the small quasi-elastic broadenings, ΔE, expected for surface scattering from a deuterated biopolymer, the spectra measured for the hydrated sample were analysed, not with respect to the instrumental resolution width W_v of the quasi-elastic line (as obtained for a purely incoherent scatterer such as vanadium), but differentially with respect to the width W_r obtained for the identical, dry or very slightly hydrated sample. Three wet-minus-dry difference spectra determined for intensity-normalised lines are shown in Fig. 2. For the same reasons, this line-shape analysis was not

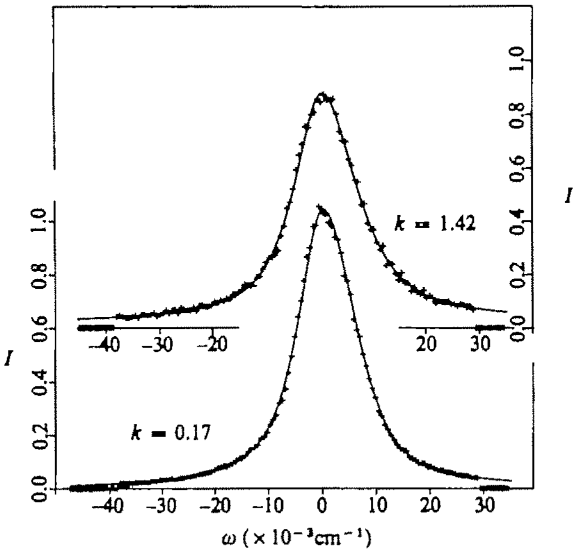

Fig. 1 Examples of quasi-elastic spectra measured (+) for phycocyanin film stacks hydrated at relative humidity $RH \leqslant 90\%$ H_2O (temperature 24 °C). I = neutron counts corrected for detector efficiency (arbitrary units); ω = energy transfer. Momentum transfer k (Å^{-1}) corresponds to scattering angles $2\theta = 9.8°$ and $90°$; resolution widths W_r (dry sample) were 0.0129 and 0.0143 cm^{-1}, respectively. Solid lines are analytical fits using asymmetric Peyre–Principi (PP) profiles[22]. The spectra shown were obtained by a backscattering technique[17] as follows. Cold neutrons from the liquid deuterium moderator (20 K) in the reactor are collimated along a 55-m guide tube. This beam consists of neutrons with a wide distribution of wavelengths in the 2–12 Å region. Reflection from a silicon monochromator crystal produces a highly monochromatic line of $\lambda_0 = 6.2708$ Å neutrons. By imparting a periodic translational motion of a few hertz to the monochromator, the neutrons selected by it are Doppler-shifted with respect to the fixed sample and continuously scan a spectral window of 0.02 Å in wavelength or 0.11 cm^{-1} in energy centred on λ_0. In a sample consisting of nuclei moving relative to each other, each elementary scattering event between neutron and nucleus is accompanied by small energy changes. Neutrons scattered by the sample are energy-analysed by 180° reflection from a fixed array of silicon crystals positioned at the scattering angle 2θ observed. The crystals forming this array reflect neutrons back on to a detector located very close to the sample.

carried out by means of conventional lorentzian fitting routines. Instead, we attempted to define a less model-dependent measure of the broadening (denoted ΔE^*) based on an integral rather than a local property of the quasi-elastic line and therefore more sensitive to non-lorentzian line-shape changes in the wings (for details, see Figs 2 and 3).

The variation of ΔE with momentum transfer k is of principal interest here. The significance of k is that the motional properties of the sample (that is, in the present case, the proton self-correlation function) are probed over a scale length of about $2\pi/k$ (Å). Thus, the macroscopic limit of classical diffusion is observed as $k \to 0$, and the behaviour of $\Delta E(k)$ for $k > 1$ to 2 Å^{-1} is dominated by the short-range translational and rotational motions. The detailed form of $\Delta E(k)$ has been investigated both theoretically and experimentally for a variety of dynamic processes[4-6,23]. The simplest case is that of continuous Fick's law diffusion for which $\Delta E = hDk^2/\pi$ where D is the self-diffusion coefficient and h is Planck's constant. The dependence of ΔE on k measured in our experiment is shown in Fig. 3. It is seen, first of all, that $\Delta E(k)$ exhibits an oscillatory structure for both the film stack and the 'fluffy' sample, with a first maximum in the broadening between $k \approx 0.3$ and 1 Å^{-1} at all H_2O hydration levels. This result clearly rules out proton diffusional motions according to Fick's law or any other bulk diffusion process for which the linewidth would increase monotonically with k and then level out at the highest k observed. Also, the effective diffusion coefficients obtained from Fig. 3 as $k^2 \to 0$ fall in the range of 10^{-7}–10^{-8} cm^2 s^{-1}, and this is one or two orders of magnitude smaller than the coefficients of diffusion observed for water in paucimolecular layers or in bulk.

For an ensemble of incoherently scattering particles migrating on a lattice of sites, model calculations[23,24] indicate that linewidth changes similar to those seen in this experiment occur whenever the residence time τ_0 of a particle at a site is large compared with the time during which it moves to a neighbouring site. The qualitative behaviour of the line-broadening results summarised in Fig. 3, if due primarily to incoherent scattering from sorbed water molecules at the protein surface, would therefore suggest water proton motions between discrete hydration sites separated by distances of the order of $1/k_{max}$ where k_{max} is the position of the first maximum in $\Delta E(k)$. The observation of lower k_{max} values for the fluffy sample seems to be consistent with this interpretation. Oscillatory structure of the kind observed here, but with higher k_{max} values, has been widely discussed in the context of neutron scattering from protons diffusing on interstitial lattice sites in metal hydrides[6,23]. Although the migration of water molecules on or near the surface of a protein cannot be expected to conform to any kind of regular lattice of hydration sites, we have nevertheless attempted to fit Chudley–Elliott (CE) jump-diffusion models[24] to the data. Because of the very limited number of data points for $\Delta E(k)$ obtained so far, the curves shown in Fig. 3 and the numbers derived from them must be regarded as illustrative of the technique rather than definitive.

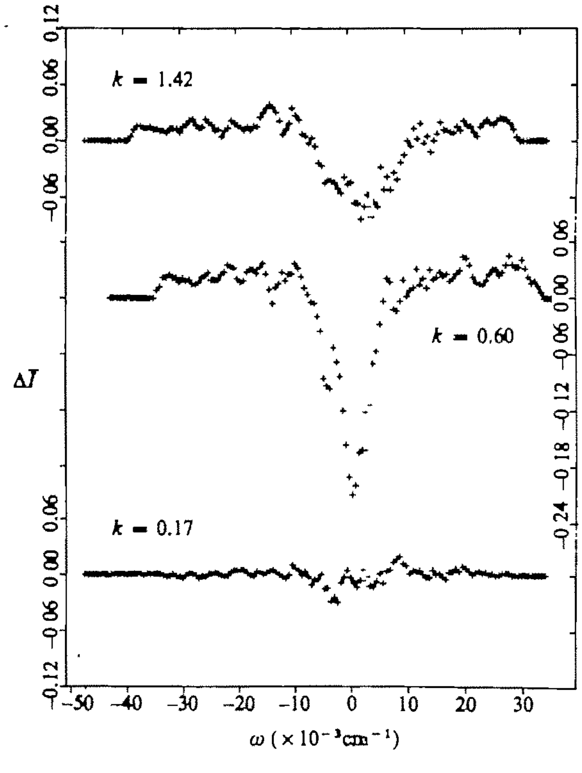

Fig. 2 Wet-minus-dry difference spectra (sample and hydration conditions as in Fig. 1) for momentum transfers k(Å^{-1}) corresponding to $2\theta = 9.8°, 35°, 90°$. For each scattering angle 2θ, the PP-fit to the resolution line $I_r(\omega)$ (dry sample) was peak-normalised such that $I_r(0) = I_{r0} = 1$, then integrated within $\omega = \pm\infty$ to give a reference intensity A_r. The PP-fit to the broadened line $I_s(\omega)$ (wet sample) was integrated and intensity-normalised according to $A_s = A_r$, to give a peak intensity $I_{s0} < 1$. The normalisation factors thus determined were applied to the measured spectra before subtraction. The bottom trace, representing the difference of the essentially unbroadened lines at the lowest scattering angle analysed, demonstrates that overall line shape changes with r.m.s. deviations of less than 2% are observable.

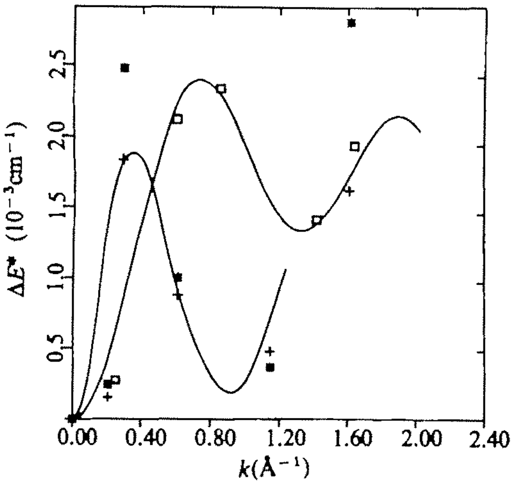

Fig. 3 Quasi-elastic broadenings ΔE^* as a function of momentum transfer k for film stack sample (☐) (hydration conditions as in Fig. 1), 'fluffy' sample at low (+) (RH = 10–30%) and intermediate (∗) (RH = 30–50%) H_2O hydration levels. Resolution lines $I_r(\omega)$ (dry sample) were peak-normalised as in Fig. 2; broadened lines $I_s(\omega)$ (wet sample) were peak-normalised in the same way so that now also $I_s(O) = I_{ro} = 1$ but $A_s > A_r$. Then $\Delta E^* = A_s - A_r$, and for purely Lorentzian profiles, $\Delta E^* = \pi/2(\Delta E_{\text{Lorentz}})$. Comparison with Lorentzian-fitted profiles gave values of 1.8–1.9 for the proportionality factor instead of $\pi/2$, demonstrating the presence of non-lorentzian line shape components.

Except at very low k, the film-stack broadenings agree reasonably well with an isotropic jump model for which $\Delta E \sim 1-(\sin ka/ka)$, the jump distance $a = 5.5$–6 Å and the residence time $\tau_0 = 5$–10 ns. The broadenings measured for the fluffy sample, on the other hand, exhibit a pronounced first minimum at $k = 0.8$–0.9 Å^{-1} that cannot be modelled in any simple way. The lower curve in Fig. 3 represents a weighted superposition of $\Delta E(k)$ resulting from one- and two-dimensional CE models, the reason for this being that at lower hydration levels one might expect the migration of water molecules to proceed preferentially along polypeptide chains at the surface. Here, $a = 7$–9 Å and $\tau_0 = 15$–30 ns. This sample was hydrated continuously from the dry state at a very low rate; the hydration number at the end of the experiment, estimated from the increase in total neutron counts, was 300±50 H_2O per subunit. The number N_r of amino acid residues offering primary hydration sites is difficult to assess because the surface structure and the degree of aggregation of subunits are not known in sufficient detail. Rough estimates would place this number in the range $100 < N_r < 200$ per subunit. The distances d_r corresponding to this range may be evaluated by covering the surface with a hexagonal grid and regarding each vertex point as a potential hydration site. This gives $d_r = 80 \times N_r^{-1/2}$ Å or $7.9 > d_r > 5.6$ Å, that is, a range of values that agrees well with the jump distances deduced from the broadening data by means of simple CE models.

In conclusion, we have presented the first high-resolution neutron spectra showing the interaction of water molecules with a fully covalently deuterated protein. We have observed a hydration-dependent maximum in the quasi-elastic broadening which, at sub-monolayer coverages, seems to be due to the jump-like migration of water molecules closely associated with or bound to the surface of protein molecules. Although more data need to be collected to substantiate this interpretation, as well as theoretical efforts to develop the analysis of quasi-elastic neutron scattering from biopolymers, the results given here demonstrate clearly that details of protein hydration processes down to energy changes of the order of $10^{-5}\,k_BT$ or 10^{-3} cm^{-1} are now within reach of neutron spectroscopic techniques. A very exciting prospect of the contrast variation method is the possibility of experiments aimed at distinguishing dynamically between the water of hydration and intramolecular fluctuations.

We thank A. Heidemann, A. J. Dianoux, W. S. Howells and K. O'Mara for discussions and technical help. Karen M. Bogle and members of the staff of the Institut Laue-Langevin, in particular J. Bauchat, provided assistance. This work was supported by the UK SRC and MRC, and the US Division of Basic Energy Science, Department of Energy.

Erratum

In the article 'Model of the fine-grain component of martian soil based on Viking lander data' by Nussinov *et al. Nature* **274,** 859, lines 1 and 2 on page 861 should read: 'can be suspended in the atmosphere, the fact that the mean diameter which can be obtained on this basis is 1–2 μm'. In line 11 on page 861, for 10^4 mol g^{-1} read 10^4 nmol g^{-1}.

Nature Index and Binders

Annual indexes are still available for years 1971 to 1977, price £5.00 each (UK), US$10.00 (Rest of World).

Binders for the journal are also available at £8.00 (UK), US$16.00 (Rest of World) for three: a year of *Nature* fits into three binders.

All prices include postage. Payment may be made in any currency at the prevailing exchange rate. Orders should be sent, accompanied by remittance, to Macmillan Journals Ltd, Brunel Road, Basingstoke, Hampshire, RG21 2XS, UK.

Q

Does BIOSIS have a "COLLECTIVE" Index?

A

Yes, we do.
It's on microfilm.

Integrated 5-year cumulations of Author, Subject and Biosystematic (Taxonomic) Indexes to **Biological Abstracts** are available now for retrospective searching of the life science literature.

- 3 cumulations: **BA** Vol. 34-45 (1959-64), Vol. 46-50 (1965-69), Vol. 51-58 (1970-74) – simplex cine mode
- 16mm silver halide film
- As cartridges or reels

Also on film – Annual Indexes for **BA** Vol. 1-33 (1927-59) and the complete abstracts file, from 1926 to right now.

Nucleic Acid Chemistry: Improved and New Synthetic Procedures, Methods and Techniques Parts 1 & 2

edited by **I.B. Townsend**, *University of Utah*,
and **R.S. Tipson**, formerly of the *National Bureau of Standards, Washington D.C.*

An up-to-date source of information on all the important aspects of the subject. Each contribution was written by experienced research workers to guide the reader by giving representative descriptions with ample details, so that even a novice will be able to apply the information. Most of the authors were investigators who had either originated these methods or acquired detailed knowledge of them through extensive use in the laboratory. The present two parts are subdivided into discussions of eight main topics.

Part 1 Contents: Heterocycles; Carbohydrates; Nucleosides.
Part 2 Contents: Nucleotides and Polynucleotides; Isotopically Labeled Compounds; Chemical and Enzymic Syntheses; Reagents, Intermediates and Miscellaneous Compounds; Instrumental or Analytical Techniques and Applications.

November 1978 556 pages

Fresh-Water Invertebrates of the United States 2nd Ed.

by **R.W. Pennak**, *University of Colorado.*

The revised edition of one of the most authoritative references on fresh-water biology. It draws on more than 5000 journal articles that have appeared since the first edition's publication in 1953 and stresses the natural history ecology and taxonomy of the free-living fauna, including aquatic insects. Details of anatomy, morphology, behaviour, and systematics for every fresh-water invertebrate group of the United States are updated. Identification keys have been rewritten, reorganized, and lengthened for all taxonomix groups. Almost 3000 individual figures are included.

Dictionary of Microbiology

by **P. Singleton** and **Diana Sainsbury.**

In preparing the *Dictionary of Microbiology* the authors have attempted to produce a compact source of readily available and up to date information for undergraduates and postgraduates in microbiology. The dictionary covers terms, concepts, techniques, tests, and other topics, and includes over one thousand microbial taxa. The entries relate to pure and applied microbiology, biochemistry, immunology, genetics, and to the microbiological aspects of allied subjects such as medicine, veterinary science and plant pathology.
The dictionary also includes a large number of cross references and an appendix of microbial metabolic pathways.

Insect Behavior

by **R.W. Matthews**, *University of Georgia*,
and **Janice R. Matthews.**

The first comprehensive overview of fundamental concepts of animal behaviour as it relates to insects. The book offers a comparative evolutionary approach that shows how a number of major behavioural systems function. Important experiments and investigations are discussed with demonstration of how behavioural research can be conducted.

CHRISTMAS BOOKS

Aesthetics and scientific progress

Martin Pollock

Two THOUSAND years ago the distinction we now make between 'Art' and 'Science' would have been meaningless. The so-called 'Two Cultures' would both have been incorporated into 'Ars' and 'τεχνη'. For the past 350 years or so Art and Science have been more sharply differentiated than ever, the latter having developed at an ever-increasing speed to alter our whole interpretation of the Universe and provide technological advances and practical solutions to a large number of our problems (if not to the really vital ones such as how to get on with each other). The edifice of Science is magnificent; yet, somewhat ironically, it has been built up at the expense of increasing restriction in the philosophical concepts on which it rests. "We forget", wrote Whitehead in 1926, "how strained and paradoxical is the view which modern Science imposes on our thoughts". Most of us do not just "forget"; the possibility never even occurs to us. We are blinded by the brilliance of our understanding and the triumphs of our technological achievements.

Nevertheless, within the past few decades, there have been increasing efforts by philosophers, artists and scientists themselves to challenge the assumptions on which Science is traditionally thought to be based and to explore the extent to which the principles and practices of Art and Science respectively may contribute to each other and be seen to share common factors in the forces which drive human beings to express themselves in these two rather different ways. After all, most people are now prepared to agree that there can be beauty, understanding and creative elements in both. In particular, scientists have to extricate themselves from the vicious circle which they themselves create when "what we notice is selected by our concerns and our concerns are excited by what we notice", as Geoffrey Vickers points out in Judith Wechsler's book, *On Aesthetics in Science* (MIT Press: Cambridge, Massachusetts, and London, $12.50; £8.75). The same point, incidentally, was made by Blake 200 years ago when he remarked that "if it were not for the poetic or prophetic character, the philosophic and the experimental would be at the ratio of all things and stand still, unable to do other than repeat the same dull round over again".

To attempt a re-analysis (albeit limited) of Science at a time when its functions in human society and the implications of its achievements are being questioned, is all to the good. Judith Wechsler's contribution has been to edit a collection of six essays by scientists all of whom "maintain that Aesthetics is a crucial factor in the scientific process". She quotes Poincaré in her introduction as saying that "in mathematics, the useful combinations are the most beautiful" and that "it is more important to have beauty in one's equations than to have them fit experiment . . ." (!) (which incidentally calls to mind Watson's and Crick's comment on their structure for DNA being "so pretty that it must be true").

The first two articles in *On Aesthetics in Science* concern the parallels between structural patterns in Art and in Nature. Cyril Smith emphasises the repetitive build-up of modular units to form a spatial hierarchy of recognisable forms in pictorial art and natural systems in physics, chemistry and biology. His description of aesthetic pleasure is "what is left over when what is expected has been cancelled out", which is charming if rather personal. It is, however, surprisingly similar to what Philip Morrison says, in the second article (on "Broken Symmetries") when he maintains that highly satisfying works of art are characterised by "faults in an otherwise regular pattern". Both these essays, stressing the analogy in the significance of similar spatial patterns in Art and Science, are open to the objection that the mind is a unity; it is not artificially divided into an Arts section and a Science section. Some congruency in pattern interpretation is to be expected. The main question is to what extent do these parallels penetrate into the deep structures of the two 'disciplines' so as to have some real significance. This needs much further research before it can begin to be properly tackled.

Arthur Miller gives an interesting (though rather difficult) analysis of the controversies in modern sub-atomic physics in terms of the distress engendered in some physicists by having to face pressures to abandon visualisation in their theorising. It is argued that the wave theory of radiation developed by Schrödinger (and supported eventually, with relief, by Bohr) was inspired by his need to visualise the elements involved; it was opposed by Heisenberg, who preferred non-visual thinking and who thought that Schrödinger's approach was "disgusting". Analogous aesthetically orientated influences operated, so Miller maintains, in the quantum/continuum "antithesis".

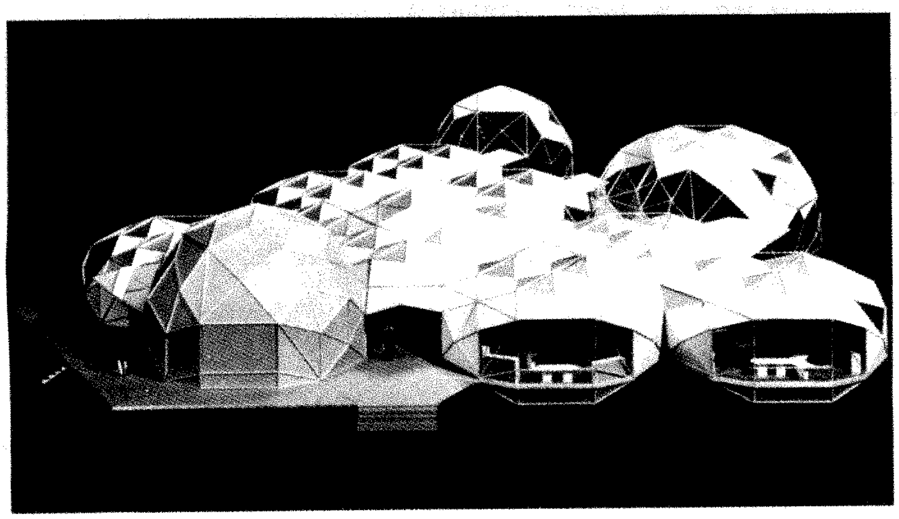
Seymour Papert extends Poincaré's theme that "Aesthetics" (working unconsciously) rather than logic "is the distinguishing feature of the mathematical mind", by analysing sequences in mathematical proofs on the basis of the aesthetic pleasure they can provide ("aesthetic guidance"). It is unfortunate, however, that the principle theorem so presented, being an entrancingly beautiful proof that $\sqrt{2}$ is an irrational number, is desperately confused (at least for the general reader) by a series of shattering misprints on pp112 and 114.

Howard Gruber illustrates what he calls "aesthetic moods" by concentrating on Darwin's evolutionary "trees" and other images used for developing scientific theories. It is the image of a concept that we love, he stresses, not the concept itself. And he rightly points out that there is a beauty in certain types of complexity as well as in simplicity. Indeed, theories do not have to be simple, as some think, in order to be "true" (that is, acceptable); they become simple with familiarity and by the need for simple presentation if they are believed to be true and have to be expounded.

Finally, Geoffrey Vickers develops forcefully and convincingly what is surely one of the most important points of all: namely, that there are indeed two different modes of "knowing" available to the human mind (two "cultures" one might say) based respectively on rationality and intuition, but these do not correspond rigidly, or even approximately, to what we call Science and Art.

The conclusion from this collection of essays is that some fundamental redefinitions and re-thinking are necessary in our approach to Art and Science. Although the pictures presented of the relationship between Aesthetics and Science are inevitably tentative and blurred, the objectives behind the book are excellent. There is a well compiled general bibliography. The articles themselves are provocatively stimulating and, although sometimes inclined to be rather turgid and verbose, are well worth studying by all those not already hopelessly rigidified in their beliefs of what Science is about. We should be grateful to Judith Wechsler for a courageous attempt to freshen and broaden our attitude.

Peter Pearce's well produced and well illustrated book on structural design, *Structure in Nature Is a Strategy for*



Model of school building designed on min-a-max system

Taken from *Structure in Nature is a Strategy for Design*

Design (MIT Press: Cambridge, Massachusetts, and London, $45; £31.50) with its curious and rather misleading title, is in one sense a formal geometrical analysis of the hierarchy of natural and man-made structures considered by Smith and Morrison in Wechsler's book. But it is really only tangentially relevant to the principles of Aesthetics as applied to Science and technology. For the general reader it is often rather heavy going. It is an exhaustive (and at times somewhat exhausting) compendium of different types of space-filling polyhedra based on a limited number of simple different polygonal surface structures, pieced together in a variety of ways. The objectives in design, both in natural and man-made structures, are—and must be—economy of energy, effort and cost (closest packing of a minimal number of different types of constructional 'unit') combined with optimal efficiency (strength for resisting internal and external strains) and maximal diversity (to meet a wide range of different environmental requirements). This leads to numerous structural similarities between natural patterns (snow-flakes, soap bubbles, honeycombs, pineapple skin, cracked mud, giraffe skin markings) and man-made structures (for example, the famous Buckmaster Fuller 'geodesic dome') according to the exigencies of different situations.

One of the more significant points emphasised by Pearce is the superiority in strength and stability of the triangle over the square as a unit side for complex polyhedra subject to various strains and stresses. This results in a series of three-dimensional structures in which the right-angle occurs relatively rarely and walls and ceilings, as we know them, have almost disappeared. The box-like construction of most contemporary architecture is thus largely abandoned. Nor are there any 'real' curves—except in so far as the so-called 'saddle polyhedra' are involved, these having sides of minimal surface area formed when the unit polygon is skew (that is, non-planar). With special properties of strength and stability, they are involved in the construction of tunnels, continuous surfaces and solidly enclosed labyrinths.

A huge range of different polyhedra is described systematically in terms of their constituent elements, illustrated by a vast number of diagrams and photographs, which will make most ordinary readers dizzy trying to work out what a monster composed, for instance, of hemi-saddle digonal disphenoids interdigitating with octahedrally truncated rhombic dodecahedra would actually be like. Yet this could, no doubt, be of great value to the experimentally minded architect really trying to break new ground in functionally improved design and cheaper construction costs.

Pearce is very production-conscious and has his own company, *Synestructics*, for developing his ideas which range from children's playground toys to homes, schools and factories. He has built many models, though, so far, no full-scale constructions. His buildings bristle with angles and slopes in all directions. They look fascinating and some (though certainly not all) are rather beautiful. Most appear bizarre to the conventional eye. In spite of the theoretical diversity available, one might suppose, from all the permutations and combinations possible of standard unit building elements provided (nodes for a variety of fixed angles, triangular plates of different sizes and shapes with opaque or transparent panels, and so on), the completed structures do not appear as different from each other as one might expect—probably because our orthogonally prejudiced eyes are blinded by all those angles. But they may indeed represent at least one important trend in the architecture of the future. Some of the constructional principles are surely excellent; so indeed is the attitude towards economy of cost and effort. But the basic Aesthetics behind these designs is elusive probably I think because no real attempt has been made to develop or expound it—if indeed it really exists. The practical elimination of the monumental curve seems to impoverish many of the designs and the suppression of the right-angle introduces a sensation of insecurity. But such reactions are so often based on personal and fashionable prejudice. To many of us, Pearce's ideas are unfamiliar, exciting and original. They surely deserve further exploration at a practical level. ☐

Martin Pollock is Emeritus Professor of Biology in the University of Edinburgh, UK.

Metaphor of the mechanical body

The Body in Question. By Jonathan Miller. Pp. 352. (Jonathan Cape: London, 1978.) £7.95.

THE medieval commentator and teacher, faced with a previously unknown book and attempting to understand it himself and explain it to others, asked of it a formal rote of questions designed to relate it to the known intellectual world. Sometimes the modern reviewer is in the same position when attempting to relate the book in question to the particular interests and expectations of the readers of the journal for which he is writing.

To explain the *Body in Question* our scholastic predecessors would undoubtedly have thought it necessary to bring into play the whole apparatus of Aristotelian causality which, given ingenuity, could explain anything: the efficient cause of the book is Jonathan Miller, intelligent and charming physician, erstwhile historian of medicine, and arch-communicator; the final cause of the book is the opportunity to take advantage of the advertising furnished by a related 13-part television series; and the material cause is some two and a half pounds of glossy paper. The remaining cause is the formal: the blueprint in the author's mind, translated into the format and content of the book.

The author at once tells us what the book is not: neither a history of medicine nor a complete survey of physiology, and it remains the reviewer's job to tell the reader what the book is. It is an attempt to use historical and modern evidence to present physiology in terms of physical science. To put it another way, it is pop physiology with history to tell us how the metaphor of the body as a machine came true—"the story of the identification of the machine within the ghost". This is a serious argument and it deserves serious review. Let us look at the history.

Perhaps the best feature of the book is the discussion of the limits of perception: how the brain's past experience leads it to impose a pattern on the data of perception, enables it to choose between alternative perceptual interpretations, and how it distorts perception by being "theory laden". The author shows clearly that this process has in the past led to "false" scientific ideas, and this is a hopeful start to the historical problem of reductionism or mechanism. But the brain distorts historical as well as scientific knowledge, and although it may be tempting for the physician to argue that "[Modern] Natural science is the native idiom of the brain made explicit", such a statement leads to a historically suspect endorsement of Miller's whiggish main thesis, that the true, mechanical, account of the body emerged only in the last century. It is not true that the medicine of the Middle Ages was characterised by "monkish superstitions", and it is not true that eighteenth century medicine was a "tissue of contradictions" with "no consistent intellectual standards and no organised body of scientific principles", or that its practitioners were "unable to make sense" of the doctrine of irritability. Miller holds that at last by the 1830s "the medical profession was almost within reach of coherent scientific credibility", but in fact it was precisely credibility of this sort that made Riolan oppose Harvey, and the College of Physicians of London oppose reform, two centuries before.

To support his argument about the development of the idea of the mechanical body, Miller naturally looks at the historical use of mechanical analogy (not metaphor) by medical writers, particularly in relation to involuntary motion and the beat of the heart. This again is a serious historical argument and the influence of the mechanical pump on Harvey's ideas has been seriously discussed by historians: it was probably negligible in *De Motu Cordis*, but it is much more likely that Harvey was influenced by the notion of a valve as illustrated by the analogy of sluice gates. This kind of argument needs very close examination of the sources, and Miller's examination of Harvey and the circulation is unsatisfactory.

Fifteen hundred years before, Galen had used the analogy of a suction-pump, and Erasistratus, an ancient even to Galen, thought the heart was a force pump, as Harvey well knew. The descriptions and relationships of Galen's physiological system, Harvey's, and mechanical analogy, are full of errors. Apart from technical mistakes, to call Galen's system "an industrial plant halfway between a brewery and a blast furnace" is to grossly exaggerate Galen's use of mechanical analogy, and to say that Harvey's quantitative arguments mark him as the "first modern biologist", who took "an altogether mechanical view of the function of the heart" and who wrote a book "with the force of great literature" is to be blinkered by twentieth-century hindsight to Harvey's great and constructive conservatism.

The author's argument is further supported by a great number of illustrations often so striking as to rival the text for the reader's attention. A dramatic, if hardly beautiful, double spread of a new born infant illustrates only that "The possession of body may be a necessary condition of being a person but it is not a sufficient one"; an illustration of a pot being turned has the solemn caption "Pottery is a typical way of making things happen . . ." and supports only a description of the role, or lack of a role of the hands in faith-healing. Is not a photograph of a large man chasing a naked boy down a dark corridor a gratuitous illustration of "A nervous system which can recognise and react to threats as and when they occur"? The technique is pure television, frozen on to the glossy page, and the reader emerges from the book like an after-dinner viewer switching off a cultural documentary with a faint feeling that his mind has been improved, but unable to quite remember the intellectual meat in the very professional presentation. No biologist will be surprised by the ideas in the book, but the layman will find that it does tell him a large number of interesting things about his own body.

R. K. French is Director of the Wellcome Unit for the History of Medicine, Cambridge, UK.

Tree appreciation

It is not surprising that the ravages of Dutch elm disease should have stimulated an attempt to produce a compilation properly celebrating the role of elms in our landscape and culture. The result of such an attempt is Gerald Wilkinson's much promoted *Epitaph for the Elm* (Hutchinson: London, £6.95). It begins with chapters on the elm in poetry and painting; but whereas the poets—particularly Clare, Edward Thomas and Betjeman—are well represented, the painters have not fared so well. Constable is featured prominently with some fine illustrations—but also some poor ones. One whole page is devoted to a postcard size view of Dedham Vale in which hardly any trees can be seen. More recent landscape painters such as John and Paul Nash have been undeservedly ignored.

The next section deals with the botany of the elm, and forty pages (a quarter of the book) are devoted to the genus *Ulmus*. Unfortunately Mr Wilkinson proves to be an inadequate guide through the labyrinth of elm taxonomy. The most widely held view today is that the Wych elm (*U. glabra*) is our only native elm, and that in the pre-Roman period there was a series of introductions to Britain of various clones of the European field elm (*U. carpinifolia*) and of *U. carpinifolia* × *U. glabra* hybrids. Other hybrids are thought to have subsequently been formed in this country. This view, based on the meticulous and scholarly research of R. H. Richens, receives no attention from Mr Wilkinson. Rather, he prefers to describe in great detail the older work of R. Melville in which a number of elm types were described as distinct native species, and he waxes very indignant that the recent editions of Clapham, Tutin and Warburg do not accept them. One's doubts as to whether Mr Wilkinson could recognise some of these elm 'species' himself are reinforced when, in dealing with the Dutch elm, that distinctive clone of southern England, he states "I have not been able to satisfy myself that [this elm] exists as a recognisable type in the English countryside".

English elm

Photo: Forestry Commission

His confusing treatment of our elm population leads him to make some very questionable statements in the next chapter, that on the elm in prehistoric Britain. It is followed however by a much better chapter on the historical period, with quotations from John Aubrey, John Evelyn and others, and by nicely illustrated sections on the past and present uses of elm wood.

Sadly, however, the book ends with a very weak section on Dutch elm disease. It is clear the Mr Wilkinson has a very imperfect understanding of the biology of the disease, and this leads him to make wild remarks such as, "even though elm bark beetles are not supposed to lay their eggs in shoots of less than ten years of age some of the pollarded elms in Suffolk are dead".

In summary, despite the fact that it is attractively presented and contains some good photographs, *Epitaph for the Elm* is too flawed to be an adequate tribute.

The Dutch elm disease epidemic is undoubtedly at least partly responsible for the current interest in trees of all kinds, and this year two new guide books have appeared. Roger Phillips' *Trees in Britain, Europe and North America* (Pan: London, paperback £3.95) is a photographic guide to "500 of the most common and important trees of the temperate climatic region". It is aimed at people with no botanical training and consists of two parts: the first comprising fifty pages of leaf photographs from which the initial identification is made; the second consisting of brief descriptions of the trees in alphabetical order, illustrated with photographs of the flowers and fruit. The "leaf index" should prove quite useful, although some of the photographs are blurred and most of the names on the first page have been transposed. The photographs of the flowers and fruit are very attractive, although here again there are mistakes which indicate that the final stages of publication were over-hurried. Nevertheless this is a book which many will find helpful and enjoyable.

The late Herbert Edlin's *The Tree Key* (Warne: London, hardback £5.95; paperback £3.95) relies on paintings rather than photographs, and there are pleasing pictures showing tree shape, summer and autumn foliage, leaves, flowers, fruit and seedlings. The main problem is that the book has the formidable ambition of being "a really practical guide for those seeking trees on either side of the Atlantic". As it is pocket-size this means that, for most trees, identification can only be to the generic level. Oddly, in view of the name, there is no key in the sense that one can systematically track down any particular tree. There is a series of classifications (leaves on the basis of shape, soft fruit on the basis of colour) but they are incomplete. Thus one cannot find *Catalpa* listed among the genera possessing "fruits with many seeds".

No doubt there are financial attractions in producing a book that can be sold on both sides of the Atlantic, but I wonder if this is really a sound policy, particularly with such a small book as *The Tree Key*. It means that some of the very limited space is devoted to species such as the Rock elm (*U. thomasii*), that are almost non-existent in Europe.

Trees by Andreas Feininger (Penguin: Harmondsworth, UK, paperback £3.95) is described by its author as "a tree appreciation book, rather than a guide or picture book". Sample chapter headings indicate its approach: "The oldest living things", "Leaves", and "Fall colours". It is illustrated by 160 photographs, mostly taken in North America but also some in Europe. Many of these are beautiful and evocative, in particular those of Californian trees such as the Redwoods and the Bristle-cone pine. There are also some pleasing black-and-white pictures of bark and weathered wood. The accompanying text of some 100 pages is lucid if slightly repetitive.

Mr Feininger's great interest in the conservation of the North American forests comes through strongly, and the book ends with a section—not very appropriate for British readers—on conservation societies in the USA. The text seems to be unchanged from the original American edition of 1968 so that some of the facts, figures and attitudes are a little dated. For example, he states that in the USA consumption of wood for fuel has declined steadily through the past century, whereas the past-five years must have seen a marked increase in its use for this purpose. **John N. Gibbs**

John N. Gibbs is a Pathologist at the Forestry Commission Research Station, Farnham, UK.

Nature's traces

PICTURES add a vital dimension to books on natural history and, with the improvement in techniques for printing illustrative material, more and more reasonably-priced illustrated biology books are coming on to the market.

Nature Detective by Hugh Falkus (Gollancz: London, £6.95) is a most handsomely produced book with many excellent black-and-white photographs. Many of these are by Niko Tinbergen, whose knowledge and enthusiasm have obviously been a major source of inspiration to the author. The pictures are the most important feature of the book and illustrate very clearly the insights that can be gained into the behaviour and ecology of animals by careful examination of the signs, tracks and droppings that they leave behind. The text provides some background information about the animals and localities illustrated.

David Stephen's *Guide to Watching Wildlife* (Collins: London, £1.75) is a paperback which gives advice on where, when and how to watch birds and mammals by day and by night. It is richly illustrated with the author's own drawings and photographs, the latter testifying to Mr Stephen's skill in practising what he preaches. The emphasis of the book is on practical skills, such as how to watch badgers, and it provides a very useful guide for those who wish to explore nature more actively.

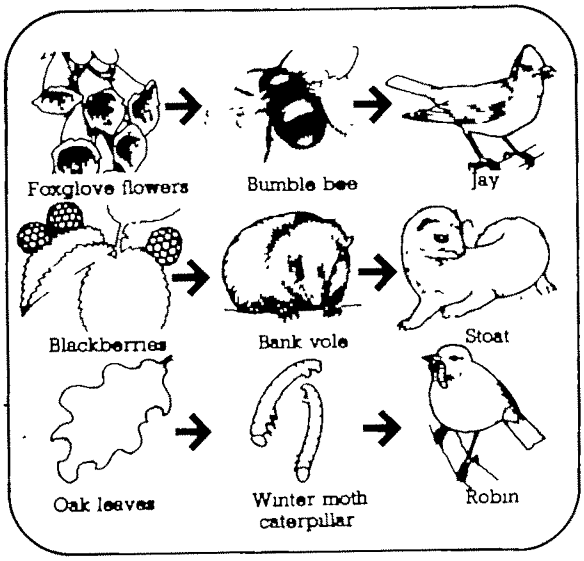
Recording Natural History Sounds by Richard Margoschis (Print and Press Services: Barnet, London, UK) is a very specialised paperback book suitable for a handful of enthusiasts and for researchers working on animal sounds. It contains much detail on principles and techniques and a number of photographs which are not generally very informative, many of them simply showing various types of tape recorder.

Nature Day and Night by Richard Adams (Kestrel. London, £3.95) is an attractively produced book, but one whose purpose is not very clear. Its theme is the way in which animals and plants are adapted to the alternation of day and night. The book has two rather different components. Richard Adams contributes a series of essays on, for example, "the meadow by day"; these tend to be rather whimsical in style. Max Hooper has written a series of scientific essays on specific subjects such as biological clocks, and David Goddard provides attractive illustrations, those for the general essays being double-page spreads crammed with animals and plants, sadly many of them too small for accurate identification. The scientific sections are excellently illustrated with drawings and diagrams and are the more successful aspect of this book.

Exploring Nature by David Hall (Hamlyn: Feltham, UK, 50p) is a practical guide for children and seeks to encourage active investigation and experimentation. Projects discussed include setting up aquaria, trapping soil animals, making spore prints from fungi and investigating photosynthesis. There is a wealth of ideas which should not only stimulate enquiring youngsters but will also be a useful stimulus to their parents and teachers.

Another children's book, *The Young Naturalist's Guide to Conservation* by Neil Arnold (Ward Lock: London, £2.95), has the admirable aim of providing practical suggestions for young people wishing to protect and encourage wildlife in their immediate surroundings. It describes how to maintain ponds, plant trees and observe birds and other wildlife. The text is concise and clear but the illustrations are somewhat variable in quality.

The *Chatto Nature Guides* (Chatto and Windus: London, hardback £4.50; paperback £1.95) are translated from German books and are illustrated by colour photographs. Each species described is covered by a photograph and a brief text giving details of characteristics, habitat and distribution. Individual titles are ***Birds*, *Wild Flowers*, *Mushrooms and Fungi*, *Insects*, *Aquarium Fishes*** and ***Minerals and Rocks***. The photographs are generally excellent, though in some instances are not suitable for the purposes of identification in the field. For example, the Cuckoo is illustrated by a photograph of a fledgling which lacks the characteristic long tail of the adult At such a low price one could not expect these little books to be comprehensive in their coverage, but there are some very serious omissions. For example, in *Birds* there is no Mistle Thrush, Lesser Black-backed Gull, Kittiwake, Dunlin or Shelduck. Perhaps these deficiencies reflect the German origin of these books; the volume on birds is notably short on coastal species. A good feature of a number of these guides is that they draw attention to instances where species may be confused with one another and emphasise the points of difference. *Mushrooms and Fungi* includes a clear code to indicate which species are palatable and which are poisonous. *Aquarium Fishes* includes hints on how each species



Woodland Food Chain—Nature at Work

Nature at Work

Introducing Ecology

This beautifully illustrated book introduces some basic concepts of ecology and interprets the relationships between plants and animals in terms of their roles as producers and consumers of energy. The plants and animals around us are constantly interacting with each other and with their non-living surroundings to form an intricate network of activity which is illustrated throughout this book with the aid of examples from two familiar ecosystems, a woodland and a rocky seashore. The book demonstrates how these two ecosystems work by following the energy flow as it is captured by plants and transferred to other living things as they feed. This account is written for the general reader who wishes to understand more about the living world. The lively and stimulating text is accompanied by many vivid and colourful illustrations specially commissioned for the book.

The book has been prepared by the staff of the British Museum (Natural History) and coincides with a major new exhibition at the Museum.

A joint publication between Cambridge University Press and the British Museum (Natural History).

Endurance of Life

The Implications of Genetics for Human Life

MACFARLANE BURNET

This is an important book in which the author, one of the most distinguished biomedical scientists of the twentieth century, examines the phenomena of old age and presents an original theory of human ageing in terms of genetics. The central hypothesis is that the changes associated with age arise, for the most part, from the accumulation of genetic errors in almost all cells of the body. The author goes on to discuss the genetic factors which, moderated by the environment, produce intelligence, temperament and behaviour. In the final chapters he discusses the genetic inheritance of modern man and the difficulties it presents in today's complex civilisation. The author suggests that antisocial behaviour is caused not simply by environment, but largely by the genes. The author has founded his argument in scientific fact, but as a pioneer in an uncharted area, he relies on analogy and speculation. The result is a stimulating and controversial work on issues which concern and touch on the lives of all human beings.

William Henry Bragg

1862-1942 Man and Scientist

GWENDOLEN M. CAROE

This biography of Sir William (Henry) Bragg is written by his daughter for the general reader and tells the life story of an eminent scientist who became a spokesman for science during the first half of the century. Sir William (Henry) Bragg and his son Sir (William) Lawrence Bragg were the first to explore the structure of crystals, using X-ray diffraction techniques, and their work was recognised by a shared Nobel Prize in 1915. There are extensive quotations from Bragg's own notes about his early life which are fine prose in themselves and have lively relevance to the present day.

'She (the author) has brought to life a big slice of those heady days when science—and physics in particular—leapt forward into atomic structures, with X-rays and radioactivity, crystallography, J. J. Thomson, Einstein and Planck.'

INTERNATIONAL JOURNAL OF INVERTEBRATE REPRODUCTION

Editor-in-Chief:
K.G. ADIYODI. Department of Zoology, Calicut University, Kerala 673635, India
Associate Editors: K.G. DAVEY, Department of Biology, York University Faculty of Science, 4700 Keele Street, Downsview, Ontario M3JIP3, Canada.
K.C. HIGHNAM, Department of Zoology, University of Sheffield, Sheffield, U.K.

Aims and Scope

The International Journal of Invertebrate Reproduction will be devoted to the rapid publication of complete papers and short communications in the following fields of sexual, reproductive and developmental (embryonic and postembryonic) biology of the Invertebrata (excluding the Protozoa). The journal will publish only papers of high scientific quality and originality, shedding new light on fundamental principles and processes. In addition, it will provide the means for better communication between researchers by the publication of penetrating and provocative minireviews, announcements, reports of meetings, news and views, notices, and book reviews.

The quality of the journal is reflected in the following list of papers included in the first issue:

R.P. Ruegg and K.G. Davey *(Canada)* The effect of C18 juvenile hormone and Altosid on the efficiency of egg production in *Rhodnius prolixus.*

D.J. Wildish *(U.K.)* Reproductive consequences of the terrestrial habit in *Orchestria* (Crustacea: Amphipoda).

D.F. Went *(Switzerland)* Pathogenesis in the dipteran insect *Heteropeza pygmaea):* an interpretation.

Uma and T. Subramoniam *(India)* Histochemical characteristics of spermatophore layers of *Scylla serrata* (Forskal) (Decapoda: Portunidae).

M. de Jong-Brink, J.P. ter Borg, M.J.M. Bergamin-Sassen and H.H. Boer *(The Netherlands)* Histology and histochemistry of the reproductive tracts of the pulmonate snail, *Bulinus truncatus,* with observations on the effects of castration on its growth and histology.

should be kept in the aquarium.

The *Penguin Nature Guides* (Penguin: Harmondsworth, UK, hardback, £1.95) have also been translated into English, from either Danish or Swedish. *Fishes of the British and Northern European Seas* has excellent illustrations by Bente Nyström to aid identification of species. There is also much interesting background information on fish and fisheries illustrated by diagrams and photographs. *Birds of Wood, Park and Garden* and *Birds of Sea and Coast* conform to the now familiar fieldguide format with excellent paintings by Lars Jonsson in which the birds look very much alive, a brief text on their natural history and characteristics, and distribution maps. *Plant Communities* incorporates the interesting idea of arranging plant species in the communities to which they belong. Separate sections deal with meadows, the sea shore, oak forest, and so on. A problem with this book is that (as is made clear in the book) many of the species shown do not occur in Britain. This is a problem inherent in books translated from another language. Also this book shows very few species and is thus of limited use as a field guide. Finally, *Fungi of Northern Europe, 1: Larger Fungi* and *Fungi of Northern Europe, 2: Gill Fungi* have excellent illustrations, among the virtues of which is that they show much of the variety of form which each species can achieve. These attractively produced books can be recommended as a reasonably priced, exceptionally well illustrated and informative series.

T. R. Halliday

T. R. Halliday is Lecturer in the Department of Biology at the Open University, Milton Keynes, UK.

Solving the problem of bird identity

THE world shrinks for the bird-watcher—and others—as 'special interest' package tours provide inexpensive ways to view new continents, where we discover birds of new families and orders of which perhaps we had hardly imagined the existence; and where we can often see familiar species in strange and exotic habitats. The television too takes its viewers to wild lands and curious creatures. Whatever way we travel, even if it is only by reading travel books, we need a source to tell us something of the characteristics and relationships of some beautiful bird seen hazily in the hot desert or all too briefly in the rain forest.

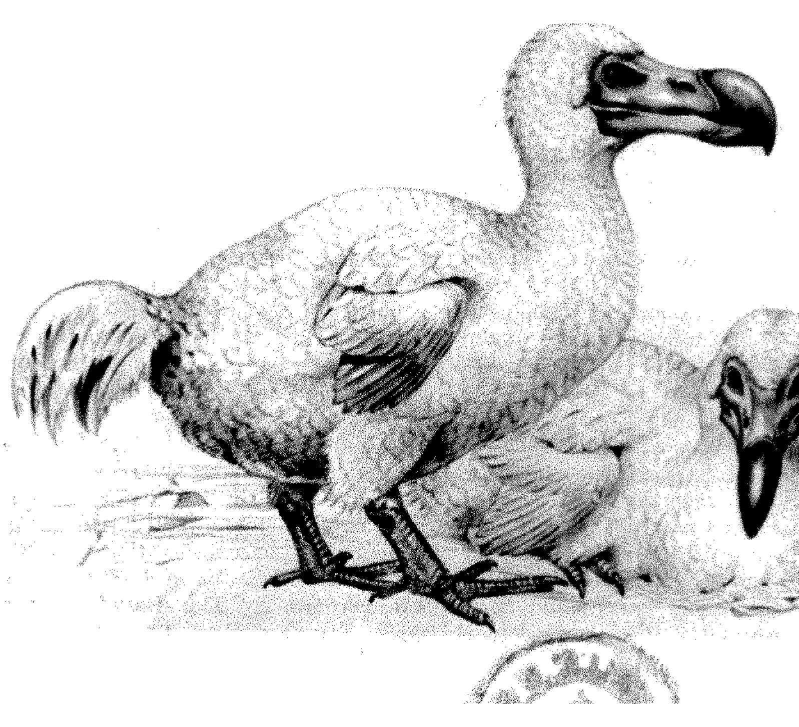
There are no fully comprehensive books on birds of the world other than checklists, and Dr Colin Harrison's *Bird Families of the World* (Phaidon: Oxford, £9.95) is probably the nearest that we can find at this price to such a survey of the families of birds existing in the world today (together with some extinct ones). Each family account is written and signed by one of 43 specialists and describes the numbers of species and genera in each family as well as noting the main features of their distribution, feeding behaviour, and nesting habits. About 900 species are illustrated by useful and accurate coloured drawings by Ad Cameron. Dr Harrison had used J. L. Peters' order for arranging his material but reminds the reader that there is another possibility and points out the alternative names and orders where they could be applied. The book is a 'popular' but serious and well-illustrated attempt to convey a picture of the main features of the birds of the world.

We don't have to travel far from home to have identification problems; moving from a world range to the identification of birds in Britain John Andrews has written *Birds* which is one of the *Nature Guides* published by Hamlyn (Feltham, UK, £1.50) and designed for the many people who wish to name easily and confidently the commoner conspicuous birds they see in their gardens, in the countryside and on their holidays. Just over 200 different species are described but only 168 are illustrated by coloured photographs. Whether colour photographs are adequate for the purpose of identification is always debated; in this pocket-sized volume most photographs do their job. But the photographs of the harriers are not really clear enough and it would have been helpful to have been told the sex of the Serin and the pied wagtail—or is it a white wagtail? Also, is the bird which is labelled great black-backed gull really a great black-backed? The contrast between the grey of the mantle and the black of the primaries as well as the colour of the legs as shown in my copy would lead me to think that it it a lesser-black-backed gull. Which all goes to show that photographs can be difficult.

John Andrews introduces his book with several paragraphs on the points to look out for when identifying birds. He gives a valuable table of habitats in which birds can be found and a short description of each species opposite each photograph. The book would make a useful Christmas present for someone, child or adult, beginning to identify birds but who does not wish to be confused by the large number of choices provided by the more advanced Field Guides.

Turning from problems of identification to other aspects of ornithology Eric Simms has written his second volume in the *New Naturalist* series, *British Thrushes* (Collins: London, £6.50), which describes some of the most familiar birds in the British Isles and in Europe. Within his compass he manages to incorporate not only the common resident thrushes, such as song and mistle thrush, blackbird and ring ouzel and the winter visitors, redwing and field fare—which also nest in very small numbers in Scotland—but also information about the thrush-like chats, stonechat, whinchat, wheatear and robin as well as these exciting vagrants which occasionally visit us from the distant north-east.

The text is illustrated by many excellent black-and-white photographs, by Robert Gillmor's pen-and-ink drawings of the displays of the different species, and by distribution maps, sonagrams, histograms and additional data supplied by experts from the British Trust for Ornithology and other organisations. Indeed the quality of the information makes this a very comprehensive volume and one which all interested in birds should have. The book, which should become a classic, is a pleasure to handle and dip into; compared with many other books produced these days it is very good value for money.



Réunion solitaire (*Raphus solitarius*), a species of dodo

Taken from *Bird Families of the World*

Guides to identify birds or their eggs are common enough and guides to bird-watching places are becoming commoner. The danger of this type of guide is that it will attract far too many people to the more delicate areas, disturb the birds and thus destroy the places they have come to see. Eric Hardy in his *Guide to the Birds of Scotland* (Constable: London, £3.95) has provided a pretty comprehensive list of places and a more comprehensive one of birds that appear in various parts of Scotland, but the bird list is rather mixed-up and makes very difficult reading. He has, however, been forbearing—careful to avoid mentioning some of the places where pressure by bird-watchers could cause big problems—and the regional maps show sufficient areas of high ornithological interest to keep bird-watchers busy for many holidays. But it is a pity that his obsessional hatred of the 'establishment' and particularly the Royal Society for the Protection of Birds, provides such a sadly sour introduction to a book which should be leading us to a greater enjoyment of birds.

While on the problems of identifying birds and their habitats, I must mention briefly another book by Dr Colin Harrison entitled *A Field Guide to the Nests, Eggs and Nestlings of North American Birds* (Collins: London, £6.50), which illustrates 622 eggs and 147 nestlings in colour. Although it is a textbook or field guide, Dr Harrison emphasises that it is for bird-lovers rather than egg collectors. For birds on the North American continent from the Arctic to the southern boundary of the USA, it incorporates basic information on habitat, nest, eggs, breeding season, incubation, nestling period, and so on. It may not appeal to the average British bird-watcher but in the United States it should become a standard work of reference.

Identification is but a first step to a deeper interest in birds and *The World of Birds* (Sampson Low: Maidenhead, UK, £3.95; the Italian author's name, Gianfranco Bologna, is rather hidden away) is the book in this collection which attempts to interest the beginner in what birds actually do. The title is rather a common one and it, or one rather like it, has been used for four or five books in recent years. What Bologna is really writing about is the way in which birds live. Many of the examples he chooses of bird biology and behaviour are common to many other recently published books on this subject and his short list of references are virtually identical to the others. What perhaps distinguishes the book is that he has used the experience of Italian authorities to supplement the standard examples. Quite clearly this book is a translation and occasionally his translator has let him down—once by referring to the "hibernation" area of the ringed plover. It is not a technical book and it could help the bird-watcher on his way to becoming an ornithologist.

The emphasis of the last two books switches from the scientific aspects of birds to the artistic. Robert Dougall in his new book *A Celebration of Birds* (Collins: London, £5.95) has left the television scene to indulge in his retirement hobby of bird-watching. He has collected together some of his own ornithological reminiscences and his favourite ornithological verse. The chapters are centred on 15 species most of which are common enough, like the robin, blue tit and sparrows, but he also goes to the other extreme and writes about the avocet and osprey. This book does not pretend to be an ornithological treatise nor a complete collection of bird verse, but rather a book for Dougall addicts with an ornithological slant. It is illustrated by drawings, some black-and-white, and some in colour.

For a selection of 36 bird portraits painted by C. F. Tunnicliffe accompanied by a practical text written by Linda Bennett, we have the *RSPB Book of Garden Birds* (Hamlyn: Feltham, UK, £2.95). The original paintings were commissioned by the RSPB as front covers for its old magazine *Bird Notes* or as Christmas cards, and in this book one finds a very good portfolio of Tunnicliffe paintings for a very low price. The main purpose of the book, however, is the practical text, describing the factors which make gardens attractive to birds, as well as the history of human interest in those bird gardens where bullfinches might even be encouraged to take fruit. It brings to mind one of the earliest practical books on bird gardening written by the Baron von Berlepsch, which still has a lot to offer. Linda Bennett gives good advice on the art of bird gardening and of course Tunnicliffe's paintings are always a delight. It would make a very attractive Christmas present.

Peter Conder

Peter Conder edits the 'News and Comment' section of the journal British Birds, *and acts as a consultant on behalf of the IUCN.*

Contributions to conservation

It would be pleasant to be able to believe that the great number of people who now support nature conservation organisations in Britain and in a few other countries do so out of commitment born of knowledge. In fact, the vast majority have joined for entertainment and, perhaps, out of a vague sense of concern. Not that there is anything wrong with that but it is important that the extent and nature of their involvement is recognised. At present, the statutory and voluntary conservation bodies operate in rather favourable conditions—private affluence and leisure meaning more public interest and support, and the national economic position inhibiting some demands on the natural environment. When times really do grow hard—as it seems they must—will the support melt away just when it is most needed? Logically, the answer must be "Yes" unless in the, perhaps brief, interim every effort is made to develop people's appreciation of nature, their understanding of the complex issues that lie at the roots of conservation and, thus, their commitment.

Any book or article, broadcast or film which starts the amateur naturalist along the road of understanding how man's activities affect wildlife is contributing to conservation. *Vanishing Birds: Their Natural History and Conservation* by Tim Halliday (Sidgwick and Jackson: London, £7.50) certainly comes into that category, treating a fairly difficult subject in a straightforward way but without avoiding the key issues.

Commencing with a general summary of avian evolution and strategies for reproduction and survival, the book examines, both in general terms and with case studies, the effect of man's past and present activities on bird populations. It is overwhelmingly clear

The development of the chick—An Introduction to the History of Virology

An Introduction to the History of Virology

A. P. WATERSON and LISE WILKINSON

This book describes the development of knowledge about the study of viruses and the diseases which they cause in plants, animals and man. Towards the end of the nineteenth century it became clear that some diseases were caused by infectious agents which differed from bacteria, but it was not until the middle of the twentieth century that a clear view of the biochemical basis of viruses emerged. The authors have attempted to see viruses through the eyes of those experimenting with them at the time, and in particular to assess their concepts of the material they were working on. It is essentially the story of ideas and of their origins, and of the formulation of the virus concept to its present-day clarity. In addition, it throws interesting light on how a scientific discipline like virology emerges as a subject separate from a larger field. The book contains much about the neighbouring fields of protein chemistry and cell biology.

'The first page catches the reader's eye by a magnificent colour plate of a bunch of variegated tulips, which has distinctive patterns attributable to an infection by a virus, the tobacco mosaic virus. From here onwards the reader will be hooked by the dazzling story of virology (many of the founder fathers are with us still) ably unfolded.'

First Paperback Edition

British Mosses and Liverworts

A. V. WATSON

This lucid introduction to British mosses and liverworts, first published in 1955 and now in its second edition, has become a standard work. The author gives full descriptions and ecological details of over 200 of the commoner and more notable species, illustrating each to show its major features. The introduction on the general characteristics of bryophytes, and the simple terminology enable a beginner to use the book without difficulty; the key and habitat lists will be invaluable to beginners and specialists alike. In the second edition there is a complete rearrangement of the liverworts to follow the current check list, a revision of the keys to both mosses and liverworts, and the inclusion of a short bibliography. In addition, there are some new illustrated accounts of the main species and species not listed before.

'It is warmly to be recommended.'

Journal of Ecology

Paperback £9.95 net

First Paperback Edition

Unpublished Scientific Papers of Isaac Newton

A. R. HALL and MARIE BOAS HALL

Now made available for the first time in paperback, this volume collects together some of Newton's most important scientific papers. Chosen primarily to illustrate Newton's ideas on the nature of matter, the papers afford valuable insights into Newton's development as a scientist and his ideas of the world that science explores. The six sections are entitled: Mathematics, Mechanics, Theory of Matter, Manuscripts related to the *Principia*, Education and Notes. Each section has a critical introduction to set the manuscripts into perspective and to discuss their implications. English translations of the Latin documents are given.

'They (the authors) have produced a significant book and have ably demonstrated the importance of supplementing a study of printed works by an examination of manuscript sources.'

GEOTHERMAL ENERGY

ITS PAST, PRESENT AND FUTURE CONTRIBUTION TO THE ENERGY NEEDS OF MAN
H. C. H. ARMSTEAD

Despite growing awareness of the potential importance of 'alternative energy' there has been, up till now, no comprehensive text on geothermal energy. Geothermal development requires the collaboration of specialists from a wide range of disciplines. This book shows how these inter-relate and how each may be applied in the exploitation of geothermal energy.

LIFE CYCLES
P. CALOW

Drawing together information from studies of development, evolution and ecology, this book considers events throughout the life cycle: birth, growth, reproduction, ageing and death. At each stage in the cycle the author discusses the physiological processes involved – the question of *how* these events take place. At the same time he asks the evolutionary question of *why* they should take place as they do – why grow? Why reproduce sexually? Why age and die? The result is a comprehensive view of the organism as a system making the best use of the time and resources available to it in order to maximise reproductive output and hence fitness.

TAXIS AND BEHAVIOR

ELEMENTARY SENSORY SYSTEMS IN BIOLOGY
Edited by G. L. HAZELBAUER

The basic mechanisms of sensitivity and response of living organisms to changes in the environment, are dealt with in this, the latest volume in Chapman & Hall's *Receptors and Recognition, B Series.*
Nine areas of active research concerning taxis and behaviour are described, each area being representative of systems in which sensory phenomena can be approached on the mechanistic and even the molecular level.

COMPARATIVE ENDOCRINOLOGY OF PROLACTIN
D. M. ENSOR

The pituitary hormone prolactin is of importance in numerous physiological functions throughout the vertebrate kingdom. The involvement of prolactin in numerous human disorders has led to an increased interest among endocrinologists and clinicians in the development of its action in all species. This book gives a comprehensive review of the available data from prolactin research, placing it in evolutionary context.

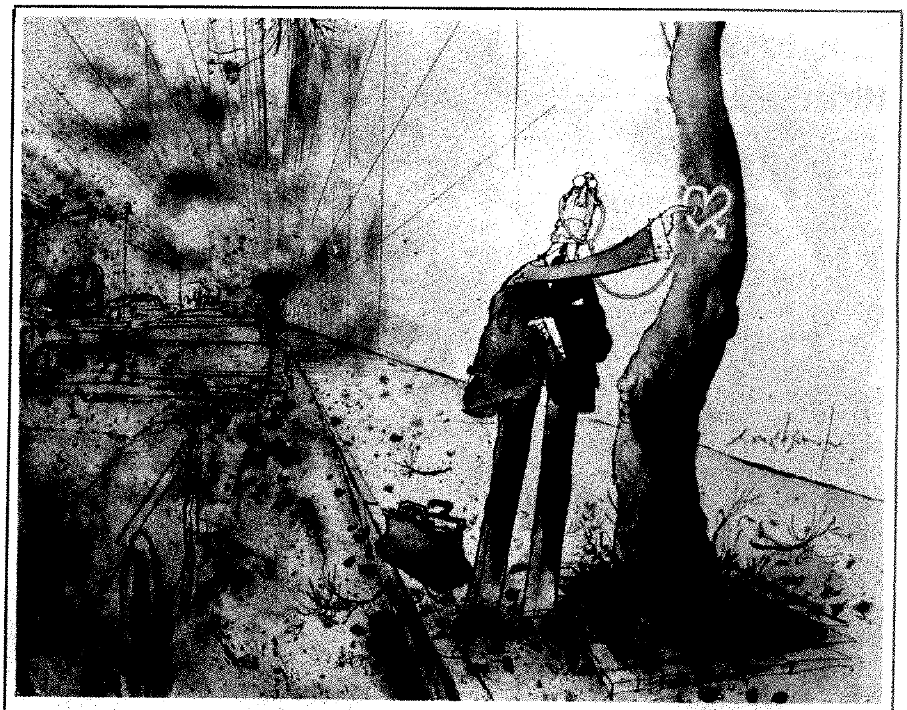
that, despite a few advances, the natural environment is exploited as energetically as ever it was—often without the justification of ignorance or great need. We deplore the feckless extermination of the great auk, not only for food but as a source of feathers: to loosen their plumage the birds were dropped into vats of boiling water, heated by burning the oily corpses of their fellows. Yet we effectively ignore the fact that the only woods in which Abbot's booby breeds are being felled in order to mine phosphates. And who protests at the stupid and criminal destruction of Amazonian forests, with their indigenous wildlife and defenceless human communities? Would there be a ban in Britain on the use of DDT if it only killed peregrine falcons and did not accumulate in human food chains also? The author argues that most of the justifications of conservation carry little weight with the general public and governments. He demonstrates weaknesses in the ethical, aesthetic, economic and scientific cases, believing that the strongest argument is ecological: we must protect the bird's environment because it is ours too. Unfortunately, many bird species could doubtless be destroyed without any significant effect on our survival or even on our wealth. The only unshakeable argument is the ethical one but its great weakness is that too few people share it.

Halliday's concluding section is a rather generalised summary of active conservation measures appropriate to endangered bird species and a wholly justified criticism of the lack of research on endangered birds. Of course, there is a dual reason for working on common species. Results are usually more certain and those results may help us to understand and solve the problems of rare and endangered birds. But if concentration on the former means neglect of the latter, the balance of research is wrong: international conservation agencies could help to redress that by careful direction of research funding.

Despite errors and omissions resulting from the fact that some information is five years out of date, which is hardly excusable in a book dealing with species whose status may be expected to change from year to year, *Vanishing Birds* is a helpful introduction to the subject, and the author's colour plates and many line drawings appear both accurate and elegant.



Cancer

Illustration taken from *Ronald Searle*, with an introduction by Henning Bock and an essay by Pierre Dehaye (André Deutsch: London, £14.50)—a superbly produced album of work by the graphic satirist.

In *Birds of Man's World* (British Museum (Natural History)/Cornell University Press: London and Ithaca, £5.95) Derek Goodwin has taken a contrasting approach with an account of his own observations of those birds which are able to exploit man-made environments, notably the urban species which are, to most of us, the common birds of the world.

The book begins with a general summary of the ways in which man's modification of his environment have created widespread conditions which benefit a rather small number of species. Thus the deforestation of Europe, much of North America and New Zealand favours grassland species: buildings provide nesting places for cliff dwellers such as swallows, martins and rock doves which were formerly much restricted by lack of suitable sites; and the ranching of domestic livestock has permitted cattle egrets—recently confined to the Old World—to colonise America and Australia. Perhaps surprisingly, it does not discuss our one outstanding domestic example—the colonisation and spread of the little ringed plover, a species which on the Continent breeds normally on shingle bars in rivers. First recorded nesting in Britain in 1938, it has since spread widely through England to Wales and Scotland, using the growing number of gravel pits created by the expanding aggregates industry.

In some ways, this book tells one more about the author than about the birds: he is refreshingly able to find pleasure and fascination in sparrows and pigeons, fully conscious of the fact that the ordered urban world we find so reassuringly safe is to them as wild and hazardous as a rain forest is to us, and that their biology and behaviour is intrinsically every bit as worthy of study as the activity of more exotic species. But because it is based on personal experience, the book provides an irritatingly incomplete study of the subject. A description of the urban birds of Colombo based on a day visit in 1965 leaves one very conscious of this.

A large proportion of the text discusses food sources but does not develop the subject of the impact of common birds on man's activities, nor of man's reactions

In Britain, the inclination is still to kill birds rather than to find alternative, if more costly, solutions. Gulls, for example, exploit man's wastefulness by resorting in great numbers to rubbish tips, especially in coastal towns. When they stay to roost on the reservoirs and to breed on rooftops or in water catchment areas, man's hand is turned against them—usually by means of ill-considered and ineffectual culling programmes. In turn, kind old ladies, conservation bodies, local councils and water authorities become embroiled in acrimonious and time-wasting disputes, which inevitably divert attention from far more important land-use problems.

Derek Goodwin's final chapter looks to the "Future Imperfect". Like Tim Halliday, and no doubt most professional conservationists, he finds little cause for long term optimism.

John Andrews

John Andrews is Head of Conservation Planning at the Royal Society for the Protection of Birds, Sandy, UK.

Conservation addicts

FOUR recently published books reviewed here are concerned wholly or in part with the effect of human activities on the fauna of the world, especially on the larger mammals. All have much to say about the decreasing numbers of some species, and of the measures of conservation taken to preserve what remains.

Dr Brian Bertram spent four years watching lions in the Serengeti Park of Tanzania, and presents the results of his studies in his well illustrated *Pride of Lions* (Dent: London, £6.50). He lived for over half the time in a shed in the bush, getting to know the local lions individually and tracking some of them by putting radio transmitter collars on them after immobilisation with a knock-out shot of paralysing drugs. His book gives a full account of the life-history of lions, enlivened by stories of his experiences and adventures. He adds chapters on the leopard and the cheetah in which he contrasts the solitary life of these species with the social life of lions. He concludes by discussing the evolution of lions, natural selection and genes, and the impact of man on lions in wildlife parks. Apart from a few solecisms, Dr Bertram writes well.

In *Tiger! The Story of the Indian Tiger* (Collins: London, £7.95), Mr Kailash Sankhala deals similarly with the tiger, but also includes much personal material—as he says, the book might be called the autobiography of a tiger addict. His formal training was not in zoology but forestry; after postings to various Forest Divisions of India, and managing the wildlife sanctuaries in some of them, he took charge of Delhi Zoo in 1965 where he remained for five years. Since then he has made a census of the wild tigers of the subcontinent, which resulted in the setting up of over a dozen tiger reserves to conserve the dwindling numbers of tigers and other animals. The first part of the book describing the natural history of the tiger, and the author's adventures in studying it, is the story of an enthusiastic naturalist enjoying the outstanding richness of India's wildlife. The author discusses, from his extensive experience, the tiger's solitary daily life, its environment, prey, co-predators and camp followers, and the other wildlife, and makes a very good job of it.

In the second part of the book Mr Sankhala considers matters such as hunting, circuses and zoos, the near extermination of the tiger and the efforts made to preserve the species. He also makes a lengthy apology for man-eaters and cattle-lifters, and adds some snooty remarks about the exploits of Jim Corbett in killing them. Nevertheless, tigers do sometimes kill and eat people. He becomes really controversial, however, when he talks about zoos and circuses, both of which he condemns as outmoded and no longer justified. When he went to Delhi Zoo he soon saw that its main role was not education but entertainment, with "riding elephants, begging bears, performing otters, smoking chimps and talking parrots . . . and the Children's Zoo a mere toy house". He did away with all this in spite of the unpopularity it brought upon him, and developed the zoo as "a wilderness with minimum signboards and direction indicators". Yet even though rare animals bred so that he was proud of his success and convinced temporarily of "the importance of zoos in conservation",' at other times he felt he had more blood on his hands than the most hardened poacher. He points out that zoos can never play much part in conserving rare species, and the craze for safari parks and zoos is not the answer to saving them. "Now that ecology, environment and the biosphere are all the rage they are suddenly changing their signboards to become 'Ecological Centres' or 'Biological Parks'. The new zoos are designed on an environmental concept", but even with the best designing they come nowhere near this ideal—even the best zoos are travesties of nature that mock their inmates. "The whole idea of bringing a free-living animal into captivity is revolting, and simply because they eat well and reproduce in captivity does not mean that a zoo is a proper environment for them".

Sick baby orang-utan rescued from an animal dealer

Taken from *Back from the Brink*

As someone has said, a zoo is a lot of wild animals kidnapped from their native freedom and locked up for uncomprehending yahoos to gape at in a sordid slum where they pitifully try to fulfill their innate behaviour patterns. The author points out that wildlife films seen by millions on television are far more educational than animals in zoos, and asks "if it is not necessary to bring the Grand Canyon or the Taj Mahal . . . into your city why should there be any justification for netting and snaring animals for educational purposes at a zoo? . . . Except for a few zoos which do a real job of contributing to knowledge their objectives are pure hypocrisy". Anyone who knows anything about the way zoos are run will, if he be honest, heartily agree. The proper place for wild animals is in the wild.

Mr Sankhala, like Dr Bertram, thinks that nature reserves as alternatives to zoos should be run with the minimum of "scientific" management. Mr Guy Mountfort, in *Back from the Brink* (Hutchinson: London, £5.50) tells of the making of some reserves, and of the ways by which several 'endangered' species have been saved from apparently imminent extermination. He is a dedicated supporter of the 'conservation movement' who draws a picture of himself as the super do-gooder, trotting about the globe addressing meetings, button-holing VIPs—he seems to like dropping names—raising money, and intriguing to get official approval for reserves and animal parks. His material is interesting, but his style of writing is that of the establishment and the old boy network—the man in Whitehall knows best.

Mr Christian Zuber, on the other hand, is a cameraman who specialises in wildlife films that are mainly shown by French television, on which he is a public figure. He, too, is an ardent conservationist but no zoologist; he consequently makes some surprising blunders in his statements about animals in *Noah's Ark: Animals in Danger* (Cassell: London, £8.95), but perhaps some of them are due to his translator. His pictures, however, are excellent, informative and interesting, though some of them cover the same subjects as those in *Back from the Brink*. It is strange that conservationists should write books with such good illustrations but such boring texts.

All these authors are much troubled that the wildlife of the world is rapidly decreasing under human depredation. The causes of world decline are many, some are unavoidable but others unnecessary and disgraceful. Foremost is the expanding human population, steadily encroaching on the wilderness to satisfy the hunger for land and what it may produce. The mad rush by Indians to cut down the forests and shoot all the animals when law and

Neurotransmitter Systems and their Clinical Disorders

edited by N. J. Legg

December 1978/January 1979, X + 240pp., £7.60/$15.75 0.12.443050.3

This book is based on a meeting held by the Department of Neurology at the Royal Postgraduate Medical School, Hammersmith Hospital, London, in 1977, and reviews selected topics in the field, dealing with them from both clinical and experimental viewpoints The range of topics matches that of the field as a whole, from the simple movement disorder of myasthenia gravis, through more complex motor and behavioural defects due to dopaminergic imbalance, to work on psychiatric disorders such as depression and schizophrenia In addition, the autonomic nervous system and its disorders are dealt with in detail.

Manipulation of the Immune Response in Cancer

edited by N. A. Mitchison and M. Landy

December 1978/January 1979, approx. 350pp., £11.50/$23.75 0.12.500250.5

The major concern in cellular immunology in recent years has been to determine the mechanisms of immune regulation. Many of the achievements so far attained could have direct relevance to the control of immune response in cancer This approach however depends on the existence of antigen specific to tumours and it was the discussion and evaluation of this question which prompted the National Cancer Institute, USA to sponsor a meeting at Oxford in the Autumn 1977 This volume represented the outcome of the meeting and follows the style of the previous Brook Lodge Symposia (Academic Press) of which it is the latest in the series

Multivariate Approximation

edited by D. C. Handscomb

December 1978/January 1979, xiv + 354pp., £12.50/$25.75 0.12.323350.X

Although both the theory and the practical applications of univariate approximation have enjoyed good coverage in books, journals and conferences, multivariate approximation has received very little specific mention, despite potentially more varied and more rewarding applications With a view to redressing the balance the London Mathematical Society convened a research symposium at the University of Durham, from July 21 to July 30, 1977, devoted to multivariate approximation This book contains the formal proceedings of the symposium, which brought together many of the best known people currently active in theoretical or practical aspects of multivariate approximation

Tables of the F- and Related Distributions with Algorithms

K. V. Mardia and P. J. Zemroch

January/February 1979, x + 276pp., £13.20/$27.25 0.12.471140.5

The key role of F,t and X^2 — distributions in statistical methodology has naturally led to inclusion of tables of their percentage points in almost every set of statistical tables. Such tables are however nearly always limited only to integral degrees of freedom and to a few percentage points. This book is believed to be the most extensive tabluation of the percentage points of F yet published and is one of the more extensive of t- and X^2 — distributions. It will therefore be of great value to all statistics workers in universities, agriculture and medical research, and industry

Diabetes, Obesity and Hyperlipidemias

edited by G. Crepaldi, P. J. Lefebvre, and G. Alberti

January/February 1979, approx. 400pp., £16.00/$33.25 0.12.197035.3

Diabetes, obesity and hyperlipidemias are topics normally dealt with separately but the Second European Meeting on Metabolism held in Padua in May 1977, encompassed all three with a view to examining their inter-relationships Among the topics discussed at the meeting and reported in this volume were, the effects of insulin and glucagon *in vitro* and *in vivo* on hepatic metabolism and the role of the liver in carbohydrate metabolism, factors regulating adipose tissue cellularity, fat cell differentiation and development of body fat mass, and the most current ideas on lipoprotein metabolism. Most of the papers reported results of recent research and this book therefore will provide much up-to-date information for all those interested in metabolic disorders including those working on diabetes, endocrinologists, epidemiologists and biochemists

The Pharmacology of Immunoregulation

edited by Georges H. Werner and Francois Floc'h

December 1978, xviii + 460pp., £16.50/$34.25 0.12.745650.3

This book contains the proceedings of the Rhône-Poulenc Round Table Conference, held in Paris in December 1977, which brought together scientists involved in fundamental Immunological research and investigators interested in clinical applications from all over the world The aim of the Conference was to confront the present, still largely empirical, trends in the pharmacological modulation of the immune responses with the rapidly increasing and sophisticated knowledge of the natural mechanisms of regulation of these immune responses

Foraminifera

Volume 3

edited by R. H. Hedley and C. G. Adams

January/February 1979, x + 284pp., £17.50/$36.25 0.12.33640.5

This is the third volume in an open-ended series containing review articles on various aspects of foraminiferal research including biogeography, biometrics, cytology, ecology, oceanography, sedimentology, stratigraphy and systematics. The series provides both specialists and general readers with up-to-date surveys of research, in which critical evaluation is combined with clear presentation.

The contributors to this volume, all experts in their fields, discuss recent advances in foraminiferal fine structure, late Cretaceous orbitoidal foraminifera, and the comparative anatomy of shell structure in some larger foraminifera

Electron Spectroscopy

Theory, Techniques and Applications Volume 2

edited by C. R. Brundle and A. D. Baker

January/February 1979, x + 288pp., £17.50/$36.25 0.12.137802.0

This series brings together the diverse types and applications of electron spectroscopy.

Contents

C. S. Fadley: Basic concepts of X-ray photoelectron spectroscopy. **S. T. Manson and D. Dill:** The photoionization of atoms: cross-sections and photoelectron angular distributions **J. T. J. Huang and J. W. Rabalais:** Ultraviolet photoelectron cross-sections and angular distributions. **J. T. J. Huang and J. W. Rabalais:** X-ray photoelectron cross-sections and angular distributions. **G. K. Wertheim:** Final-state structure in XPS. Subject index.

Rotating Fluids in Geophysics

edited by P. H. Roberts and A. M. Soward

December 1978, xviii + 552pp., £17.50/$36.25 0.12.589650.6

The subject of rotating fluids is worth studying for many reasons, not least of which is that all the large scale motions of the Earth's atmosphere, oceans and core are dominated by its rotation This book is devoted primarily to a theoretical exposition of the subject, although several sections are centred on experimental and numerical techniques in their applications to the atmosphere, oceans and core of the earth. A theme running through the book is waves of stability, supported by a brief section expounding hydrodynamic stability theory This book will bring the student and researcher up to date with the latest findings in the field as well with some fresh developments of the basic principles. It will interest not only postgraduates in fluid mechanics, meteorology, oceanography, and geophysics, but the more theoretically inclined astro-physicist or cosmologist.

Advances in Optical and Electron Spectroscopy

Volume 7

edited by R. Barer and V. E. Cosslett

January/February 1979, xii + 398pp., £19.60/$40.50 0.12.029907.0

This series attempts to cover all aspects of microscopy In this volume two articles deal with problems arising from the study of moving objects, where the application of modern technology offers solutions to long standing problems In the remaining articles the emphasis is on the physical principles of image formation and interpretation, such as the determination of the dimensional structure of macromolecules and the prospects for imaging single atoms. As with the previous volumes it is intended that this volume will be of interest to all those who use microscopy in both the biological and physical sciences.

Fundamentals of Freeze Drying

edited by R. D. Mellor

January 1979, xxviii + 386pp., £20.50/$42.40 0.12.490050.X

The search for the best means of preserving perishable foodstuffs has been continuing throughout the history of mankind. Until recently, both freezing and drying have been practised, but have never been combined Only over the last two or three decades has the process of lyophilization or freeze-drying been developed and used extensively The need for a systematic and scientific approach was clearly acute so since 1958, international courses have been run to investigate the physicochemical bases of the process and to monitor its applications This book reflects this concern and sets out in a comprehensive fashion the background to the principles for the use of both research and technical workers as well as students in food science, process and chemical engineering, physics and biology

Virus-transformed Cell Membranes

edited by Claude Nicolau

January/February 1979, viii + 408pp., £21.00/$43.50 0.12.518850.9

The information contained in this book should clarify many aspects of membrane structure and function in virus-transformed cells. Three areas of research in particular have been investigated: the identification of the surface property or properties associated with loss of growth control, the definition of the surface glycoconjugate alterations that are associated with high oncogenic potential, and the definition of surface membrane changes common to cells transformed by viral, chemical or physical agents Also discussed in detail are transport across the membrane of virus-transformed and serum-stimulated cells, and the use of lectins as probes of the transformed cell surface

Selected Topics in Graph Theory

edited by Lowell W. Beineke and Robin J. Wilson

February/March 1979, xii + 452pp., £21.50/$44.50 0.12.086250.6

One of the consequences of the recent rapid expansion in graph theory is that it has become increasingly difficult to ascertain what is currently known about any particular topic in the field In view of this the editors have collected together a series of expository surveys written by a distinguished group of authors, covering various areas of graph theory An important feature of the book is that a uniform terminology, style and notation has been adopted throughout While some knowledge of elementary graph theory is assumed, all the necessary definitions and theorems used in the book, are described in the first chapter thereby making the book most useful for advanced courses and seminars

Luminescence Spectroscopy

edited by M. D. Lumb

December 1978/January 1979, xii + 376pp., £24.00/$49.75 0.12.459550.2

Luminescence spectroscopy has become too large a field for a single volume to adequately cover the whole of it, even at an introductory level This book, however, provides sufficient theoretical and experimental groundwork to give a newcomer to the field a firm basis from which to follow up particular aspects of the subject. It reviews the experimental use of both the luminescence process and magneto-optical effects in organic and inorganic systems, as well as giving a certain amount of theory, necessary for the reader to understand the principles of the spectroscopic method

Pulmonates

Volume 2A: Systematics, Evolution and Ecology

edited by Vera Fretter and John F. Peake

January/February 1979, xii + 540pp., £24.50/$50.75 0.12.267502.9

The Pulmonata are that subclass of the Gastropoda which includes all the non-operculate land snails and slugs, and a few families of freshwater, brackish-water and marine snails and limpets, most of which respire, at least in part, with a "lung" Where *Volmue 1* was based on laboratory work, *Volume 2a* of this study is oriented towards "field" problems, dealing with the systematics, evolution and ecology of pulmonates. *Volume 2b* will concentrate on the economic importance of a particular species, *Achatina fulica* Both parts will not only be of immediate value to malacologists, ecologists, physiologists and naturalists, but will provide, along with *Volume 1*, a lasting reference guide to these fascinating molluscs

Archaeology of Afghanistan

From earliest times to the Timurid Period

edited by F. R. Allchin and Norman Hammond

January 1979, xxiv + 452pp., £30.00/$62.00 0.12.050440.5

This book is the first synthesis of the archaeology of Afghanistan, a region often described as the "Cross-roads of Asia"; a melting-pot of cultures between India, Iran and Central Asia. These three areas were the seats of major civilisations in the prehistoric and historic periods: Afghanistan, landlocked in its mountains and deserts, lay on the margins of all of them, involved politically and culturally with each from time to time. This marginal location relative to any one area was also, paradoxically, central to the three together, so that the culture which developed in Afghanistan over the centuries was neither Indian, nor Persian, nor Central Asian, but a unique amalgam of all three

Nucleation and Growth of Thin Films

B. Lewis and J. C. Anderson

January/February 1979, approx. 400pp., £27.50/$57.00 0.12.446680.X

This book provides a comprehensive survey of the theories of nucleation and the initial stages of growth of thin films The first two chapters are concerned with the adsorption of atoms on surfaces and the forces which keep them there With this as a foundation the processes of nucleation and growth of clusters are considered in detail, using both kinetic and thermodynamic treatments Particular attention is paid to the common ground between apparently diverse treatments such as the classical and atomistic nucleation models and the uniform depletion, lattice and ring models of surface diffusion capture

Annual Reports on NMR Spectroscopy

Volume 8

edited by G. A. Webb

December 1978, x + 380pp., £28.00/$58.00 0.12.505308.8

The major aim of this widely-acclaimed series it to provide timely accounts of those areas of NMR spectroscopy where significant advances are being made In recent years the advent of FT—NMR techniques has shifted the emphasis away from proton NMR towards less receptive nuclei such as ^{13}C and ^{15}N which are now being studied routinely in many laboratories This, and recent progress in the theoretical interpretation of NMR parameters, is reflected in this series which covers NMR applications in all branches of science The present volume contains chapters which should appeal to workers in many branches of chemistry, physical, organic, inorganic, theoretical and biological

Advances in Marine Biology

Volume 15

edited by Sir Frederick S. Russell and Sir Maurice Yonge

January/February 1979, xiv + 560pp., £31.00/$64.25 0.12.026115.4

The book opens with a comprehensive review by C J Corkett and I A. McLaren on the biology of *Pseudocalanus*. This is probably the most abundant copepod in temperate latitudes and as such is the most important link in the food chain leading from the phytoplankton to fish The second article by M. R Reeve deals with the nutrition of ctenophores. These act detrimentally in the food chain for they are voracious predators which may at times decimate the copepod population as well as the young fish themselves This is followed by a short article by F S Russell outlining the many ways in which a study of marine biology may have an important bearing on human affairs The volume ends with two valuable reviews on pollution and plankton

Biology of the Reptilia

Volume 8: Physiology B

edited by Carl Gans and K. A. Gans

January/February 1979, xiv + 786pp., £35.00/$72.50 0.12.274608.2

This widely acclaimed series provides an up-to-date and comprehensive review of the class Reptilia. It is divided into sections on morphology, embryology, physiology, and ecology and behaviour, each volume presenting summaries of the state of knowledge in a particular area written by leading specialists in the field well qualified to evalute the achievements in the area The latest volume deals mainly with the venom gland system, the biochemistry and pharmacology of venoms and the production of antisera, as well as an account of digestion in snakes in view of the close association between the two *Volume 8* has much to interest pharmacologists, toxicologists and biochemists

The Medical Management of the Critically Ill

edited by Gillian C. Hanson and P. L. Wright

January/February 1979, xviii +1052pp., £45.00/$93.25 0.12.323650.9

This book will fill a serious gap in the literature on critical patient care and should be particularly useful to doctors and ancillary staff who devote most the their time to the management of the critically ill. It will also be of value to specialists interested in specific aspects of intensive care and to doctors who rarely encounter critical illness but who want guidance on this subject In addition, many nurses and technicians who work in Intensive Therapy Units will find this volume a source of helpful information

order broke down at independence was typical. A second cause is the commercial value of wildlife products that leads to ruthless exploitation; apart from whales, there is the trade in turtles and their eggs, the gathering of colonial-nesting sea birds' eggs on a vast scale, the poaching of ivory and rhinoceros horn secretly condoned and participated in by corrupt administrations in Africa, the killing of crocodiles and lizards for the luxury leather trade, the hunting to supply the demands of the fur trade with pelts of all kinds, from vicuña to tiger, leopard and other large cats. But international agreements to protect some species and control the trade in their products are now beginning to have some effect.

The worst threat to wildlife, however, is the development of remote places for the tourist trade. Remote and beautiful places are disfigured with airports and huge hotels to which hordes of tourists are brought on package holidays. The once placid countryside is invaded by speed boats and water skiing, spear fishing, discos, noise, disturbance and destruction of habitat. The traders in eagerly bought souvenirs are ransacking the remotest shores of the tropics for rare sea-shells, despoiling island faunas to provide stuffed baby crocodiles and iguanas, and encouraging the poachers to supply animal skins and carved ivory. Wildlife parks where animals are preserved provide no safeguards—tourists may be valuable money spinners, but they have to be housed, air-strips and roads must be made to get them there, electricity, water and sewage works supplied, catering organised, the animals 'managed' by wardens, and so on until the whole thing is as artificial as a 'safari park' in a developed country; the tourist industry is a vast humbug. Guides take the tourists to photograph the animals—Dr Bertram in his landrover once found he was followed closely by eight minibuses and cars full of tourists, and he gives a photograph of a tourist minibus, with camera snappers, harassing a lioness at close quarters Mr Sankhala also remarks that the snap-shotting tourist is so preoccupied with shutter speeds, lens apertures and focussing that he fails to see anything around him, and adds that a visitor to a reserve should bring nothing with him but a receptive mind and take nothing away but what it receives.

It is inevitable that, in spite of the craze for wildlife, within a hundred years the wilderness will be tamed, the larger wild animals that have not become extinct will be contained within fences, and development will have destroyed the spirit of freedom. The only way to preserve samples of the fauna is to isolate reserves in which no human disturbance is allowed, such as the area between Seronera and Lake Victoria that formerly was a closed reserve free from human footprints or car tracks. But will the developers agree to large parts of their countries being sterilised against their enterprise? The call of money is louder than the voice of the wilderness.

L. Harrison Matthews

L. Harrison-Matthews was Scientific Director of the Zoological Society of London from 1951–66.

Protean nature of conservation

THREE of the four books reviewed here (that of Maurice Burton is the exception) could come under the heading of conservation but their diversity emphasises the protean nature of the term. Definitions are many and various (if ventured upon) but I know none so comprehensive and thoughtful as that of Charles Elton in his Ecology of Invasions, *viz.* "some wise principle of coexistence between man and nature, even if it has to be a modified kind of man and a modified kind of nature".

These three recently published books, among many others, suggest that, at the moment, the lion's share of this modification has fallen to nature while man is panting behind. Richard Williamson's *The Great Yew Forest: The Natural History of Kingley Vale* (Macmillan: London, £5.95) is a fascinating and first-hand account of his struggles, as warden of Kingley Vale National Nature Reserve, to understand and maintain the unique yew forest with its interspersed chalk grasslands; it shows how hard it is to stem the influence of man even in a nature reserve. It is a first-rate, thoughtful naturalist's book and will be enjoyed not only for its vivid observation but for its searching out of natural processes.

In contrast, Richard Perry's *Wildlife in Britain and Ireland* (Croom Helm: London, £7.25), published in association with the World Wildlife Fund, is avowedly a compilation about the history of the bird and mammal fauna of the British Isles since the last Ice Age It gives special attention to the social pressures that have, for example, eliminated wolves and bears and subsequently borne hard on predators generally and, by contrast, allowed the penetration by exotic species such as the muntjac and sika deer from patrician zoological collections or nutria and American mink from commercial drive. There is some evidence of the beginning of a modified kind of man in his attitude to nature in that animals are less regarded as simply subserving his needs or pastimes. Mr Perry's collation of the prehistory of

An Introduction to Animal Behaviour
Third Edition
Aubrey Manning
In this new edition, the main aim has been to keep a broad biological approach to the subject. There has been a considerable amount of rearrangement of the material to take account of new attitudes to behavioural problems. Thus, for example, imprinting is now considered under the discussion of development, and the contents of the hitherto separate chapter on hormones and behaviour, are now considered with those on development and motivation where they are most relevant. Sections on communication and on sociobiology are the most important new additions and serve to introduce students to some of the results and concepts in these active research areas
Cloth £12 Paper £5.95

Organization in Plants
Third Edition
W. M. M. Baron
This is the third edition of a very successful text on plant physiology for both introductory biology and botany courses at universities and in sixth forms. The book has been extensively rewritten to keep abreast of recent discoveries Much more information on the growth and development of plants is included to stress that the survival of the plant as a species may depend on *all* stages of its life cycle.
With illustrations throughout
Paper £6 75

Micro-organisms
Function, Form and Environment
Second Edition
Edited by Lilian E. Hawker and Alan H. Linton
This second edition of a highly acclaimed text has been largely rewritten and re-structured to take account of recent developments in the field. The editors have organized the material around the three main themes of physiology and biochemistry, natural history and classification, and interaction with the environment, to produce a logical and readable text covering the whole field of microbiology
With illustrations throughout
Paper £8.95

Circle No 22 on Reader Enquiry Card

our fauna is valuable, even if the details are not minutely documented. I could detect no serious errors, though it was startling to find (p63) the strawberry tree flourishing at 10,000 feet in the Alps. This, presumably, refers to the alpine bearberry (*Arctostaphylos alpinus*), which was previously put in the genus *Arbutus*. The great value of the book is to give us some measure of the mutability of the things we try to conserve quite apart from the ever-increasing pressure exerted by the numbers and activities of man.

A quite different aspect of conservation is treated by Lawrence Alderson in his book *The Chance to Survive: Rare Breeds in a Changing World* (Cameron and Tayleur/David and Charles: Newton Abbot and London, £7.50)—namely, the urgency of preserving the breeds of horses, cattle and pigs which, having gone out of fashion, are in danger of being permanently lost. I would not have thought it possible that, being a straight zoologist, my interest and enthusiasm could have been aroused by a theme so much on the fringe of my usual thinking. But Mr Alderson writes so well and with such conviction that I found myself carried along and taking in my stride the welter of British Whites, North Ronaldsays and Gloucester Old Spots (shades of Michael Innes!). His main contention is that, nowadays, breeders of livestock are too concerned to concentrate on specialised characteristics which suit the immediate market, especially in the conditions of indoor cosseting. So breeds that are thrifty and can live on marginal land tend to die out. Yet these may be just the ones that will be needed when environmental and economic conditions change. The book is a plea that such breeds should be regarded as valuable gene banks and it points to how much has already been achieved by the enthusiasm of recently formed breed societies and by the formation of the Rare Breeds Survival Trust. Darwin would have found this book a worthy extension of his *Animals and Plants under Domestication*, especially as so many of the principles of genetics, which were a closed book to him, have now been unravelled. Nevertheless, the impression conveyed by this book is that there is still a long road to travel before the complexities of inheritance in our farm animals are fully elucidated.

These three books, therefore, illustrate forcibly what I have referred to above as the protean nature of the concept of conservation: yet all have some common aim—that of preserving faunal diversity. Kingley Vale is a unique ecosystem and it is good to know that its ancient yew forest is safe from despoliation and cared for by a warden who wants to know "what makes it tick". The problems of management of the British vertebrate fauna, involving so many divergent interests from those who practise agricultural monocultures to those who cannot bear to see blood spilled cannot even be approached without an evaluation of its present status and past history, such as Richard Perry has tried to provide in his book. Finally, the stock-taking of farm animal breeds and the plans that are being put into action to deep-freeze semen and ova of vanishing strains, whose qualities may be urgently needed in a cloudy future, must counteract the gene pools that, once vanished, are gone for ever. Thus, we hark back to "a modified kind of man and a modified kind of nature". The main kind of modification of man so far exhibited is a deeper appreciation of and concern for the preservation of diversity and richness of ecosystems, habitats, flora and fauna. This is an aim on which, in this country, the Nature Conservancy Council and its allied research branch, the Institute of Terrestrial Ecology, have always concentrated their energies. It is, and will be, an uphill fight until the pressure of man and his activities is lightened—one hopes by planning in the best sense and not by catastrophe.

The last book of the quartet, *Just like an Animal* (Dent: London, £5.50) by Maurice Burton, is just like Maurice Burton—a concatenation of anecdotes about animal behaviour ranging from that of ants to that of his own, and other people's, pets. The theme is altruistic behaviour in animals and many of the episodes quoted are, as Darwin said about the natural history of the Galapagos Islands, "eminently curious", though they do not add up to such far-reaching conclusions.

H. N. Southern

H N. Southern recently retired as Senior Research Officer of the Animal Ecology Research Group in the Department of Zoology, University of Oxford, UK

For herpetological novices

THE latest of the Collins' *Field Guides*—*A Field Guide to the Reptiles and Amphibians of Britain and Europe* (Collins: London, £4.95) by E. N. Arnold and J. A. Burton—is a perfect gem, a delight to the eye and a pleasure to handle—a fine, solid, book with a well designed and illustrated, waterproof cover. In Europe, west of 36E, there are about 45 species of amphibians and 90 species of reptiles, including five sea turtles, all of which are described and illustrated with the aid fo numerous diagrams, 126 distribution maps, and 40 superb coloured illustrations from drawings by D. W. Ovenden. It really does show how dreadfully the British fauna must have suffered from extinctions during the Ice Age—I can hardly wait for our next holiday in Europe.

The book contains some delightful touches of realism which must surely appeal to professional zoologists as much as to absolute novices. For instance, the following approach to identification is recommended—first, "try to match your animal's appearance as closely as possible" to one of the species shown in the plates. Then "check with the text and maps that you are within the range of the species concerned". "If the range fits, consult with the description in the text and, lastly, if all else fails, try using the keys". No hypocrisy here about using keys first, and then checking the descriptions and illustrations.

It is suggested that a photographic record be made of reptiles and amphibians seen, but the keeping of pets is discouraged. "The average semi-moribund captive tortoise bears no comparison with the alert, vigorous, herb-scented beasts that plough through the undergrowth of southern Europe. Observing wild animals is far more entertaining, and less demanding, than the drudgery of keeping them". All interesting animals found dead can, however, be preserved, and the reader is informed that, in emergencies, quite good results may be obtained with "the stronger grades of brandy, gin, anis, slivovica, tuica, rakija, schnapps, or ouzo". Yet another advertisement for a continental holiday.

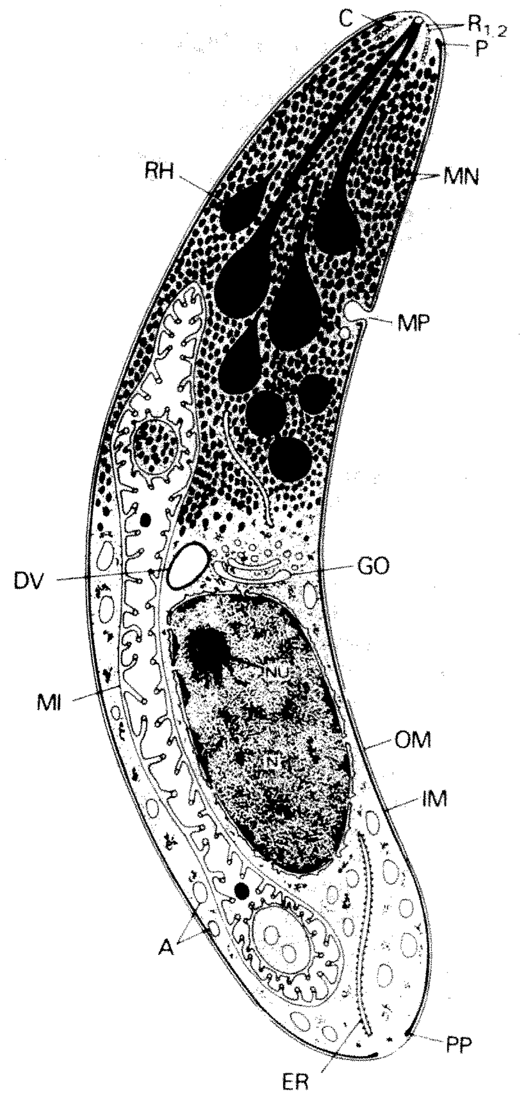
The World of Amphibians and Reptiles (Sampson Low: Maidenhead, UK, £3.95) is a second attractive volume for people with herpetological interests. Although translated from an Italian original it is quite well written. Indeed, it seems both surprising and unfortunate that the author's name should have been withheld. When reading a book, I prefer to know whose ideas I am absorbing. And although, presumably, written mainly for students and amateurs, the book under review does propound some genuinely interesting ideas as well as others that seem rather odd. For instance, amphibians can tolerate cold better than reptiles, especially in regions where the climate is dry: many Hynobiidae are to be found in the cold, but muddy, tundra regions on the Siberian border. The Plethodontidae "have a fixed mandible and in order to chew or swallow they have to move their jaws, and with them the entire cranium"(?). Nocturnal Bufonidae move with small, clumsy hops, as their hind legs are very short—the causal relationship, if any, is not, however, elaborated.

Interesting comments and speculations are made as to the functions of cloacal and muchal-dorsal glands in snakes, predation by land tortoises, the pineal eye of *Sphenodon* and lizards, egg-teeth and caruncles, the sticky membrane of some chameleon eggs which gives them a hold on a branch, and stomach stones

E. Scholtyseck

Fine Structure of Parasitic Protozoa

An Atlas of Micrographs, Drawings and Diagrams



1978. 186 figures. Approx. 220 pages
DM 80,–; US $ 44.00
ISBN 3-540-09010-X

Prices are subject to change without notice

This atlas utilizes a new method of analyzing electron micrographs allowing a more definitive characterization of protozoan fine structural organization. An electron micrograph and an analytic drawing are arranged, along with a descriptive text on pages facing each other to facilitate comparison.

Although emphasis is placed on the cytological structure of a selection of parasitic protozoa, functional, developmental and ecological aspects are also stressed.

The literature is brought up to date with new information on the ecology of parasitic protozoa and on fine structural studies of their developmental stages in the natural host, in cultural cells and in defined media. Problems of host specificity as well as those of parasite-host relationships are discussed.

The atlas is designed for students, instructors, and researchers in the fields of protozoology, parasitology, veterinary or human medicine, and makes a valuable tool in the study of fine structure in general.

Contents:
Introduction. – Classification. – Abbreviations. – Fine Structure: Subphylum: Sarcomastigophora. Subphylum: Apicomplexa. Subphylum: Microspora Parasitic Protists of Uncertain Systematic Position.

In recent years, there has been growing recognition of the pivotal importance of trace elements in all areas of biological, environmental, and biomedical research. Many trace elements are now known to be essential for life. Others are dangerous toxicants and pollutants. And some are both essential to various plant and animal species at certain intake levels, and poisonous to the same or other species at different levels of ingestion

Because original research papers dealing with trace elements have been widely disseminated throughout the primary journal literature, ***Biological Trace Element Research*** has been established to serve as the new and much-needed central forum for this powerfully emergent, interdisciplinary field. Its concentration will be on investigations of individual elements rather than on methodology or narrow discipline-oriented work as such. Not a biochemical journal *per se*, Biological Trace Element Research will emphasize the integrative aspects of research in these fields, relating human and animal nutritional studies not only to the fundamental chemistry and biochemistry at issue, but also to the elucidation of the relevant aspects of preventive medicine, epidemiology, clinical chemistry, agriculture, endocrinology, animal science, pharmacology, microbiology, toxicology, virology, marine biology, sensory physiology, developmental biology, and so on

Call for Papers/Instruction to Authors

Three copies of all manuscripts submitted for consideration should be sent either to the Editor-in-Chief, G. N. Schrauzer, or to one of the Editors. Authors from the Eastern Hemisphere (Australia, New Zealand, Japan, India, Hong-Kong, etc.) may find it preferable to send their manuscripts to Dr. E. J. Underwood, University of Western Australia, Nedlands, WA, 6009.

The original manuscript should be complete with tables, references, footnotes, charts, figures and legends, and must be written in English. All material must be typed double-spaced on one side of consecutively numbered 8½ × 11" pages, and should be concise and consistent in style, spelling, and the use of abbreviations. The first page of each manuscript should provide the Title of the article, the Authors' Names (without degrees), the authors' Affiliations, a running title (not exceeding 40 letters and spaces), and an asterisk identifying the author to whom proofs, reprint requests, and other correspondence should be directed. Suggestions of possible referees by the authors are welcome.

Authors are strongly encouraged to use descriptive headings in this order. Abstract, Key words, Introduction, Methods, Results, Discussion, Conclusions, Acknowledgements, and References. References should be cited in the text by italic numerals in parentheses, and should generally follow ACS Handbook style. Abbreviations of journal titles should follow the style used in *Chemical Abstracts's Service User Index*, 1969 Edition.

of crocodilians. We are also told that snakes "spend most of their time half-asleep, and the only stimuli that can rouse them from their state of torpor are hunger-pangs (due to a previous period of fasting, due in turn to laziness) and sex".

On the other hand, there is no serious discussion of the physiological significance of cutaneous respiration in Amphibia; the origin of the cleidoic egg is barely mentioned; adhesion of the gecko's foot to smooth surfaces is explained without reference to friction; the ability of *Chrysopelea* to glide is stated without comment; and physiological thermoregulation in reptiles barely mentioned. The problem of the coloration of coral snakes is not analysed and no reference is made to Mertensian mimicry in this context. Nor can I accept the argument that, as the colours of chameleons are most cryptic when the animals are relaxed, their function is not so much for defensive reasons, but rather to give them a chance to attack a prey unseen.

The two sections into which the book is divided are provided with introductions which explain clearly how each class has evolved to its present status. These sections are followed by accounts of structure, physiology, reproduction, behaviour, ecology, and classification. A detailed bibliography of relevant books is included. The text of some 60,000 words is illustrated by over 200 colour photographs and drawings, but the latter are not always related to the text and are of inferior quality to those of the Collins' *Field Guide*: some are distinctly crude and inadequately labelled. The index too is incomplete. Despite such comparatively minor inadequacies, the book provides an excellent introduction to amphibians and reptiles and can be confidently recommended as a Christmas present that will give interest and pleasure.

J. L. Cloudsley-Thompson

J. L. Cloudsley-Thompson is Professor of Zoology at Birkbeck College, University of London, UK.

Portraits of the Lepidoptera

"KILL not the moth nor butterfly" wrote Blake, and three recently published books reviewed here echo his sentiments, though they are in defence of conservation (or just sheer artistry) rather than because "the Last Judgment draweth nigh". All three have superb illustrations and none refers to the killing bottle or setting board.

Robert Goodden's *British Butterflies: A Field Guide* (David and Charles: Newton Abbot and London, £4.50) is perhaps the best organised. It really is a field guide, and starts with a section on the life-cycle, breeding and conservation of British butterflies, and one can see from it how much there is still to be learnt about their habitats. Every species is photographed alive and with each there is a rough distribution map. For the beginner difficulties of size are overcome by the charts at the front and back of the book, which show the insects (the common ones at the front and the rarer ones at the back) at approximately three-quarters their size. There is advice on how to encourage butterflies to visit gardens and an exhortation for the enthusiast to join the British Butterfly Conservation Society in Leicestershire. The book is for the uninitiated of all ages, and for the old hand is a "must" simply for the breathtaking photographs.

Umberto Parenti, in *The World of Butterflies and Moths: Their Life-Cycle, Habits and Ecology* (Orbis: London, £5.95) looks at some of the many facets of the world of butterflies and moths. The photographs are of unbelievable beauty, and it seems churlish to have to criticise them by saying that they are arranged often randomly, both geographically and for the text, and that there is no indication of the actual size of the insects. The book is at its best in the information which it gives about the evolution of the Order, its anatomy and physiology, the methods of reproduction and the way the insects adapt to their environments, with sections on mimicry, camouflage and pheromones. The least satisfactory section is the classification, which is difficult to take in, and being necessarily short is over-compressed for such a vast subject. In spite of some unevenness the book is strongly recommended, and would make a splendid Christmas present.

Stuart McNeill's examples of British butterflies and moths, in *Butterflies and Moths* (Michael Joseph: London, £11.95) have been selected from the famous series of Christian Sepp and his son, the engravings first being published in Holland in 1762. The introduction explains the technique of copper engraving and gives a history of the Sepp family. The text relating to the insects is up to date, and one notes that the Peppered Moth was true to its name in the Sepps' day—the "dark, Satanic mills" which were to bring industrial melanism being still in the future. The book is recommended more for bibliophiles and nature lovers than for either beginners or specialists in the Lepidoptera. The restrained beauty of the plates makes the exuberance of the colour photographs in the other books seem vulgar, and yet it is interesting how accurately both can portray the insects.

Cyril A. Clarke

Sir Cyril Clarke is Honorary Nuffield Research Fellow in the Department of Genetics, University of Liverpool, UK.

The Cambridge Encyclopaedia of Astronomy

Editor-in-Chief: Dr Simon Mitton,
Institute of Astronomy,
Cambridge.
Foreword by the Astronomer
Royal, Sir Martin Ryle

The most advanced and comprehensive work ever to appear on astronomy — of the highest scientific standard yet cleverly arranged, with very full indexing, to make easy and fascinating reading for the informed layman.

500 illustrations (150 in colour), all entirely new, as well as a 14 page star atlas, based on definitive sky maps prepared by the Smithsonian Observatory.

'A wealth of useful and up-to-date information.' *Journal of the British Astronomical Association*

'This excellent guide to the Universe . . . easy to read and lucid. The choice of photographs is excellent and there are some stunning full page (20 x 20cm) colour pictures of nebulae.' *Nature*

'An outstanding success: it is worth every penny of the price charged for it.' *The Times Educational Supp.*

Lifecloud
The origin of life in the universe
FRED HOYLE &
N. C. WICKRAMASINGHE
In this revolutionary new theory about the extraterrestrial origins of life, the authors argue that life did not start here on earth, but that a primitive biological system evolved in interstellar space and was carried to our planets, and probably others, by meteorites.
'The authors argue their hypothesis well . . . this book contains much information which is not readily available in such a palatable form elsewhere.' *New Scientist* £5.95

Pride of Lions
BRIAN BERTRAM
Until recently, almost nothing was known about the way lions lived in the wild. Brian Bertram spent over four years in the Serengeti studying undisturbed lions there — this book is the result of his research, and is for anyone who enjoys looking at animals and would like to know more about them.
'This is a stimulating book with many interesting photographs by the author, and is warmly recommended.' *Wildlife Magazine*
Illustrated with 8 pp of colour plates and over 100 black and white photographs £6.50

Just Like an Animal
MAURICE BURTON
A highly readable account of the amazing ways in which animals show unusual behaviour.
'The delightful studies in animal tenderness portrayed in Maurice Burton's *Just Like an Animal* epitomise the caring the author has found in a great variety of creatures. . . . This book makes one feel it would be a compliment to be told one 'behaves like an animal'.' *Daily Mail*
Illustrated with 36 photographs and 19 line drawings £5.50

Natural selection in wildflower books

WILDFLOWER BOOKS in Britain are now proliferating at a rate which almost matches that of bird books. This is indicative of a large and growing market among adult amateur naturalists as well as among the more enthusiastic element within school and university classes. It is not easy to classify flower books, but one might begin by dividing them into field guides, the chief intention of which is to aid the process of identification, and coffee-table books, which rely on the aesthetic appeal of elaborate photography or artwork to attract a market. On thumbing through a selection of recently published flower books one soon realises that this dichotomy is unreal and that most books actually lie along a continuum of variation between these two extremes.

In Britain we have been well supplied with illustrated field guides, in particular D. McClintock and R. S. R. Fitter's *Pocket Guide to Wild Flowers* (Collins: London, 1956) and W. Keble Martin's *Concise British Flora in Colour* (Ebury: London, 1965). Both of these sought to provide comprehensive coverage of the British flora in the form of illustrations and notes on identification and distribution. Many taxonomic botanists have been unhappy with the development of such books, for students are apt to use them uncritically when identifying plants and prefer to look through pictures rather than work through keys. Undoubtedly such misuse of these books does occur, but on the other hand illustrations can be most valuable in confirming identifications and in exciting the interest of incipient naturalists. On this ground alone, in my opinion, they justify their existence.

In a similar vein to these earlier works is *Wild Flowers: The Wild Flowers of Britain and Northern Europe* (Collins: London, £5.95) by M. Blamey, R. Fitter and A. Fitter, which is now available in a large format, hardback edition having previously been published as a paperback pocket-sized book. Illustrations are now, unfortunately, separated from the text and although a taxonomic order is adopted, only English names appear on the plates. This is a great disadvantage over the Keble Martin text, especially where students are concerned. Some of the English names used are not entirely satisfactory, such as 'dwarf thistle' for *Cirsium acaule*, instead of the usual 'stemless thistle'. Some habitat details are inaccurate: *Dianthus superbus* is said to be found in dry places; in Fennoscandia it is found largely on riversides. Problems have arisen as a result of the separation of illustrations from the text (they were interleaved in the paperback edition); there are errors in cross-referencing and those species which were mentioned but not illustrated in the paperback are now omitted entirely. This means that the book is far less comprehensive (such a common species as *Cirsium palustre* is lacking) in its coverage.

The justification for this new format edition with reduced text is the desire to display Marjorie Blamey's illustrations to better effect. This is certainly achieved and the plates are of a high quality. One must, however, compare them with those of Keble Martin and they fail to measure up to the earlier paintings on either aesthetic or technical grounds. Take, for example, the pictures of *Eriocaulon septangulare*; in Keble Martin's illustration the flower structure is clearer, the grooved, spiral stem is visible and the cell structure of the leaves is evident. All of these are useful criteria for identification and are lacking in Marjorie Blamey's work. It is only fair to add, however, that recent editions of Keble Martin's drawings have deteriorated in their quality of reproduction.

Roger Phillips' *Wild Flowers of Britain* (Pan: London, paperback £4.50) approaches the illustration problem by means of a series of colour photographs, yet it remains essentially at the 'field guide' end of the spectrum. The approach has been used quite successfully in the past by Oleg Polunin in such books as his *Flowers of Europe* (Oxford University Press: Oxford, 1969). There are two novel features in Phillips' book: the plant material in the photographs is picked and arranged in a studio setting. The photographs are most effective and the freshness of the specimens is extraordinary. One could object to the technique on conservation grounds but rarer species such as *Gentiana verna* and *Dianthus gratianopolitanus*, are either represented by garden specimens, or habitat shots are used which do not necessitate the destruction of the plant. The other novel feature of the book is the arrangement, which is based upon flowering time, and where appropriate it includes fruit in due season. The coverage is quite full, including some non-native species such as *Cornus mas*, and the mixing of illustrations with text makes it easy to use. This is a valuable contribution to the popular botanical literature, though I still prefer the drawings of Keble Martin.

The Hamlyn attempt to invade the field guide market with Helen Pursey's *Wild Flowers* (Feltham, UK, £1.50) falls short in every respect except its low price. Only 220 species are dealt with and yet the geographical coverage includes northern Europe. The selection of plants included seems to be random; for example, the only species of *Melampyrum* described is *M. cristatum*, which is probably the least likely species of the genus to be encountered in northern Europe. On these grounds alone it is more likely to frustrate than to satisfy or inform the beginner.

Cloning Reagents from BRL

Terminal Transferase - T4 DNA Ligase

Regardless of how you construct your plasmid chimaera, BRL terminal transferase and DNA ligase are guaranteed to get the job done

BRL's T4 DNA ligase has excellent activity for joining blunt (base paired) ends of DNA—a rigorous challenge of ligation efficiency For homopolymer "tailing" of duplex DNA, you can expect terminal transferase from BRL to add at least 50 residues dAMP or 200 residues dTMP per strand within 30 minutes (λ DNA ends)

BRL Terminal Transferase and T4 DNA Ligase the reagents of choice for cloners the world over

Reconciling Man with the Environment

Lord Ashby

'Lord Ashby's cogently argued and well-documented analyses of democracy at work make fascinating reading From them one sees at once why governments are often deemed to be "muddling through" a crisis . . . . The book is full of little gems of judgement over the whole range of specialist fields involved . . . . You will not agree with them all, but you cannot fail to be stimulated.' *The T.H.E.S.* £4.25

Perspectives on Energy

Issues, Ideas, and Environmental Dilemmas

Lon C. Ruedisili and Morris W. Firebaugh

The new edition of this anthology, first published in 1975, is a thorough revision of the original, and now includes twenty-six articles. Its purpose remains the same: to illustrate the complexity of the present energy crisis, the wide diversity of proposed solutions, and the environmental implications of these alternatives. The treatment is non-mathematical and interdisciplinary, covering ethical, social, political, and economic issues. Second edition Illustrated paper covers £6.95

The Environment as Hazard

Ian Burton, Robert W. Kates, and Gilbert F. White

Floods and earthquakes have been called natural hazards, and are ascribed to nature, environment, or God. In this new and highly original book, hazards are seen as human events – a product of man. The density and distribution of population, the style and level of economy, the shape, size, and character of buildings, the patterns of production and consumption all affect the consequences of the natural event. This book explores the sweeping implications of this concept. Illustrated £5 paper covers £2.95

Soil Sampling and Soil Description

J. M. Hodgson

This book provides a comprehensive review of the methods of soil and site description used in soil survey throughout the world. The author discusses the problems of using these methods and shows how to produce a proper description of a soil profile. The book will be useful to field workers and students in soil science and related disciplines, as well as to ecologists, agriculturalists, and geologists. Illustrated £10 *Monographs on Soil Survey*

NOW AVAILABLE

EARTHQUAKES:

Cause, Prediction, and Control

J. H. TATSCH

This is no ordinary book on earthquakes. Nor does it simply detail the gross characteristics of the Earth's seismicity. Rather, it shows how the Earth's seismic characteristics have originated, how they have evolved, and what causes today's earthquakes. It does this by using a single, long-lived, deep-seated, global mechanism that has been operating within the Earth during the 4.6 billion years that the Earth is believed to have been in existence. This mechanism is the "tectonospheric Earth model", which has been described in the book, *The Earth's Tectonosphere (1972)*, and used as the basis for the correlative follow-on books, *Mineral Deposits (1973)*, *Petroleum Deposits (1974)*, *Gold Deposits (1975)*, and *Geothermal Deposits (1976)*, by the same author.

Chapter heading: 1, The Earth's seismicity: a global survey; 2, The Tectonospheric Earth Model: a new concept; 3, The geometrical, mechanical, thermal, and chemical behaviour of the Earth during the past 4.6 billion years: a summary; 4, Plate tectonics, omniductive processes, and seismotectonomagmatic belts; 5, The Galapagos-to-Gibraltar segment of the Cenozoic seismotectonomagmatic belts and the associated geoseismicity; 6, The Gibraltar-to-Bengal segment of the Cenozoic seismotectonomagmatic belts and the associated geoseismicity; 7, The Bengal-to-Kermadecs segment of the Cenozoic seismotectonomagmatic belts and the associated geoseismicity; 8, The Kermadecs-to-Galapagos segment of the Cenozoic seismotectonomagmatic belts and the associated geoseismicity; 9, The Aleutians-to-Galapagos segment of the Cenozoic seismotectonomagmatic belts and the associated geoseismicity; 10, The Galapagos-to-Bouvet segment of the Cenozoic seismotectonomagmatic belts and the associated geoseismicity; 11, The Bouvet-to-Bengal segment of the Cenozoic seismotectonomagmatic belts and the associated geoseismicity; 12, The Bengal-to-Aleutians segment of the Cenozoic siesmotectonomagmatic belts and the associated geoseismicity; 13, The Aleutians-to-Gibraltar segment of the Cenozoic seismotectonomagmatic belts and the associated geoseismicity; 14, The Gibraltar-to-Bouvet segment of the Cenozoic seismotectonomagmatic belts and the associated geoseismicity; 15, The Bouvet-to-Kermadecs segment of the Cenozoic seismotectonomagmatic belts and the associated geoseismicity; 16, The Kermadecs-to-Aleutians segment of the Cenozoic seismotectonomagmatic belts and the associated geoseismicity; 17, Vestiges of Pre-Cenozoic seismotectonomagmatic belts and the associated geoseismicity; 18, The cause, prediction, and control of earthquakes: a summary.

This book, composed almost entirely of proprietary material, summarizes the results of an independent research project undertaken to determine the most probably geometrical, mechanical, thermal, and chemical aspects of the origin, evolution, and present characteristics of the Earth's seismicity. Because of its proprietary nature, very little of this material has been published in journals. Nor is it expected that very much of it will be offered for publication other than in book form. This unified approach to the analysis of the cause, prediction, and control of earthquakes, we feel, permits the reader to gain a better perspective of the subject matter presented.

Available directly from the address shown below or from book dealers in all parts of the world. Hard cover 6 x 9 inches, 451 pages. Table of contents, line drawings, index, maps, references. $108.00. ISBN:0-912890-02-9. LC:75-9305. 1977.

J2017

Circle No. 20 on Reader Enquiry Card.

Collins (London, £5.95) has recently taken the daring step of issuing *An Atlas of Wildflowers of Great Britain and Northern Europe* compiled by Alastair Fitter, consisting of almost 2,000 maps of species distribution in northwest Europe. It is a daring step in that such a book cannot hope to have the immediate appeal of the colour picture book, yet it must be regarded as one of the most valuable contributions to popular botany of the decade. Apart from the obvious use of such maps in plant hunting, the enthusiast who has learned basic plant identification from the field guides will now be able to consider what environmental factors, such as climate and human modification of habitats, are instrumental in the production of the distributions described here. It should also provide a more balanced attitude to conservation of the British flora, for, although such glamorous species as *Cypripedium calceolus* are bound to attract much effort on the part of preservationists, some of the most distinctively '*British*' plants are the oceanic heathland types such as *Ulex gallii*. This realisation may increase public awareness of the need for the conservation of these internationally scarce habitats which we rather take for granted.

Lys de Bray's *The Wild Garden: An Illustrated Guide to Weeds* (Weidenfeld and Nicolson: London, £6.95) concentrates on weed species and falls closer to the coffee-table end of the spectrum than the field guide end. It is very much a folk lore type of book with an abundance of legendary material and herbal recipes. John and Susan Proctor's *Nature's Use of Colour in Plants and Their Flowers* (Peter Lowe/Eurobook: London, £3.95) also gives an initial coffee-table impression, especially in its lavish full-page colour illustrations of flowers like *Strelitzia* and of fruits like the apple. It does, however, go far beyond this level in discussing the nature and function of plant pigments, and of pollination mechanisms. A chapter on plant mimicry is particularly valuable, as this is a subject rarely dealt with in popular texts. Both Batesian and Mullerian mimicry are explained and illustrated from the plant kingdom. Parts of this book could be read by sixth-form (advanced school) students and first-year undergraduates with great benefit.

North American plant books are represented in this list by a field guide, *Wildflowers and Weeds*, by B. Courtnay and J. Zimmerman (Van Nostrand Reinhold: Wokingham, UK, paperback £5.30) and by a coffee-table book, *Wild Flowers of Canada*, by M. Ferguson and R. Saunders (Van Nostrand Reinhold, £15.15). The latter contains some superb colour photographs of plants arranged in habitats and links these to brief, if prosaic, text descriptions. With only 150 species described it does not provide adequate information for identification. *Wildflowers and Weeds* consists of a series of small colour photographs covering 650 species from the Great Lakes area. Arrangement is taxonomic and text notes are reduced to a bare minimum. The small size of the photographs and their poor quality of reproduction limit the value of this book, which otherwise emulates the approach of Polunin in Europe. It presents no challenge to the Tory Peterson guides in North America.

Finally, there is a coffee-table book by W. P. A. Jackson, *Wild Flowers of Table Mountain* (Howard Timmins: Cape Town, £12.95), which has some excellent photographs of flowers growing in their natural setting on Table Mountain, South Africa. The text is informative and interesting and should appeal to horticulturalists with a penchant for the Cape flora.

The radiative evolution of flower books seem to be operating on a number of major lines. Photographs are taking over from detailed and accurate artwork, which is unfortunate. Some attempt is being made to provide information over and above that which is relevant to identification; this is to be welcomed. What needs to be developed is the use of simple keys to add precision to the identification processes (for example, with the yellow Composites) and the placing of plant species into habitat contexts so that their interactions can be better appreciated.

Peter D. Moore

Peter D. Moore is Senior Lecturer in the Department of Plant Sciences, King's College, University of London, UK.

Orchid guide

A Field Guide to the Orchids of Britain and Europe with North Africa and the Middle East. By J. G. Williams, A. E. Williams and N. Arlott. Pp.176. (Collins: London, 1978.) £4.95

SOONER or later, most amateur botanists reach a point the popular, general floras seem not to describe their latest discovery, while the specialised works are too bulky, too costly, or only available in a library. Those whose problem lies with identifying wild orchids, not only in Britain, but virtually anywhere within reach of the home-based holiday traveller, should be frustrated no longer, for this new field guide ranges geographically from the Azores to the Urals, by way of Iceland and the countries of the Maghreb. It describes and illustrates 138 species, as well as a large number of sub-species and varieties, is small enough to go in the pocket, and is very reasonably priced.

Oncidium lanceanum (Orchidaceae)

Mary Evans Picture Library

The lay-out is convenient, each description being faced by the relevant illustration, although the very small type may prove a problem for those whose sight is not what it was. A few introductory paragraphs are followed by a key to the genera—which seems a trifle unnecessary—and more detailed keys to *Ophrys* and *Orchis*; the authors have wisely not attempted a key to the complex genus *Dactylorhiza*. In general, the *Flora Europea* classification has been followed, but it is unfortunate that means of correlating this with the nomenclature adopted in older floras are not provided. Descriptions of the individual species are in general sufficient and accurate, although there may still be some frustration over sorting out the scarcer Mediterranean species of *Ophrys*, and, inevitably, the Dactylorhizas. Some mention might have been made, too, of the many interesting, puzzling and not uncommon inter-generic hybrids which are features of the family as a whole. One might also query some of the authors' assessments of the rarity of certain species, and their data on distribution are not always as complete or up-to-date as they might be.

The illustrations are perhaps somewhat less satisfactory. At least as here reproduced, they do not reach the high standard attained in other books in this series, and it is at times evident that, as is made clear in the Introduction, the artist has worked from the authors' sketches, and has never seen the living plant. Considerable attention is given, too, to enlargements of parts of no particular value as aids to identification by the ordinary amateur. Two excellent features that follow the main text are an unusually full glossary, and a check list wherein the reader can record his or her own personal finds. In general, these are minor criticisms of points easily rectifiable in a later edition; they certainly do not detract from the general usefulness of a book, which fills a notable gap in the amateur botanist's library. **Peter Collins**

Peter Collins is a freelance science writer who has been studying the orchids of Europe for more than 25 years.

Armchair geology

THE mere statistics of wilderness areas are impressive enough. The Earth's surface contains something like 18×10^6 km^2 of desert, about half of which is accounted for by Australia and the Sahara. And to this 12% of the total land surface must be added 11% under permanent ice cover, 9% covered with mountain, a further 9% of cold and waterlogged tundra, and 29% of otherwise uncultivable continent comprising semi-arid regions, bare rock, frost-prone areas, and so on. Taking the oceans into account now, only 9% of the Earth's surface can be cultivated and only about a third of that is actually tilled.

To be able (by courtesy of the BBC) to escape from man's narrow well-beaten tracks from time to time to make a series of television programmes about the world's varied wildernesses, Anthony Smith, the naturalist-broadcaster (as opposed to the political scientist-broadcaster and the medical journalist of the same name), was indeed privileged. His book, *Wilderness* (Allen and Unwin: Hemel Hempstead, UK, £7.50), though obviously a spin-off from the series, is not the "book of the film" in the usual sense but, rather, an independent personal account involving a mixture of description, observation, reaction, interpretation, background and anecdote relating to his visits to the world's largest ice-sheet (Antarctica), the biggest tropical forest (Brazil), a large desert (central Australia), the highest mountain range (Himalayas), the tundra (northern Canada) and the most extensive swamp (Sudd).

"Discovering a nest", says Smith at one stage with unconscious irony, "is more rewarding than being shown ten of them." Precisely—which is why all travel books are inherently unsatisfactory. Whether you like or dislike this one will depend on whether or not you can bear to visit places through another person's words. Generally I cannot; but because of the unusual nature of the places, I managed to overcome the resistance in this case and was rewarded with a pleasant afternoon, not least because of the superb colour plates.

But if Smith's book is the closest most of us are likely to get to the true wilderness, the phenomena described by P. J. Banyard in his *Natural Wonders of the World* (Orbis: London, £5.95) are more accessible, as they lie mainly within man's proportionally small terrestrial domain. Landforms, ice patterns, water displays, atmospheric phenomena, gurglings from the Earth's interior, exotic flower arrangements—they are all here in a combination of pleasing pictures and straightforwardly factual text. It makes for a nice browse; but there is a sense of *deja vu* about it all, for what we are looking at is just the latest version of the world picture book that grandma bought us for our eleventh birthdays. There is little one can fault Banyard on; lest it be lack of inspiration; but it is at times like this that one comes to appreciate Anthony Smith's sense of personal quest and involvement.

Involvement of another kind is inherent in Alan Woolley's *Illustrated Encyclopaedia of the Mineral Kingdom*, (Hamlyn: Feltham, UK, £5.95) for mineralogy in its simplest form, the collection of minerals, is the most popular of geology's branches, at least as far as the amateur is concerned. I presume that this new Hamlyn encyclopaedia has been produced largely with the non-geologist in mind, but non-mineralogical Earth scientists will also find it useful as far as it goes. Its main defect as far as working geologists are concerned is that it only goes as far as about 300 of the world's 2500 or so minerals (generally the most common and widely distributed but including a few rarer ones of greater than usual interest to mineral collectors).

For the chosen 300, however, all the essential information is given (composition, hardness, lustre, occurrence, and so on) and the colour photographs are good. On the other hand, the book is far from being a mere list, for there are summary chapters on the Earth's structure and history, crustal composition, minerals and rocks in their geological environments, crystals, gemstones, economic minerals and the building of a mineral collection. This book too is but a variant of its numerous predecessors over the years; but within its stated limitations it is far more authoritative and better produced than most.

Aggregates of minerals (that is, rocks) are generally less colourful than some of the pure minerals and thus less popular as collectors' items. The most colourful specimens in *Rocks of the World*, (Pergamon: Oxford, £15), which is not a book but a neatly-mounted set of 36 of the world's most basic rocks, are the laterite, the serpentinite and the ignimbrite; but despite the preponderance of greys the collection is a fascinating one, not least by the way it suddenly appears in one's hand without all the effort of collecting individual samples. Armchair geologists of the world will rejoice; but schoolteachers will not be displeased either, for a good collection of basic rocks is, of course, essential for beginning geology classes. The samples are rather small (up to about 4 cm across) and, being mounted, cannot easily be handled by a group of students. As a purely visual display, however, the set can hardly be faulted.

Peter J. Smith

Peter J. Smith is Reader in the Department of Earth Sciences at the Open University, Milton Keynes, UK.

For budding holographers

Understanding Holography. By Michael Wenyon. Pp. 176. (David and Charles: Newton Abbot and London, 1978.) £5.50.

THIS book is intended for the general reader and starts with two chapters about light and the laser in which various ideas relating to waves, coherence, interference, stereoscopic images, stimulated and spontaneous emission, and so on, are introduced in a non-mathematical manner. There follows a short digression on the applications of lasers in such fields as medicine and laser light shows before a discussion of the principles of holography. The basic ideas of holography are considered from the diffraction grating approach, and a well informed reader may have thought that more insight into the process would have been obtained, had the idea of the grating been extended to include the Fresnel zone plate. The effects of the size and spectral content of the light source used in the reconstruction process are, surprisingly, not considered in detail.

The chapter on display holography makes entertaining reading and there are many illustrations (necessarily two dimensional) of what has been achieved in this field. It is possible to make holographic pendants, three dimensional abstract light patterns and rainbow cylinder holograms; and even Salvador Dali has shown an interest in the technique. As for the future of holography, the author tells us that holographic movies already exist and could well become a viable proposition on a large scale. There is, however, a sinister comment that "life-like 3D movies could also be used in the future for psychological conditioning or brainwashing". Holographic television, it seems, is unlikely to be realised in the near future Apart from its obvious entertainment value, holography can be used in a more serious vein, as illustrated by the accounts of applications in the study of the vibration modes of musical instruments and the testing of car tyres.

The final chapter is an account of how to make your own holograms with simple equipment. Perhaps the easiest way of making a simple hologram is to use conventional fine grain film and to ensure there is a small angle between the object and the reference beam. It is a pity there is no mention of this experiment, if for no other reason than the relative cheapness of the photographic material. Also the double exposure scatter plate experiments could have been described as they are easy

On Aesthetics in Science
Judith Wechsler, editor

"An interesting collection of essays about modes of scientific thought . . . But each essay is the product of many years of mature reflection and so has its own particular insights to contribute. What might have been an assorted jumble emerges eventually as a satisfying whole." *New Scientist.* £??.??

Structure in Nature as a Strategy for Design
Peter Pearce

An innovative and completely illustrated approach to architectural and environmental design, *Structure in Nature* is based on a study of responsive and adaptive structures in nature (molecules, crystals, living cells) that conserve energy and material. 245 pages, 391 illustrations. £??.??

ENERGY AND THE ENVIROMENT

Democratic Decision Making

Edited by J. Surrey, Christian Lenzer, C. Phipps and J. Valleix

The outcome of a lively conference at the Council for Europe in Strasbourg, this book examines the challenges facing Europe over the next quarter-century arising from the complex and interrelated problems of energy and environment policy.
The stark choice confronting politicians the report says, is between on the one hand, allowing societies to maintain present life-styles and trends and neglecting the risk of future resource scarcity, and on the other hand of preparing public opinion for unpopular decisions needed to avert future crisis.

Contents

Introduction – Energy Needs, Resources and their Conservation, 1985–2000 – Non-nuclear Energy Resources and their Environmental Impacts – The Nuclear Option: For and Against – Future Policies – The Closing Sitting and Communique.

Publication: 14th December; £5.95; 0 333 25627 1

PHYSICS

A SHORT COURSE IN CLOUD PHYSICS 2nd Edition

R.R. Rogers, *McGill University, Montreal*

The aim of this book is to survey, in a short volume, the more important aspects of cloud and precipitation physics. The early chapters review atmospheric thermodynamics, providing a background for chapters on the nucleation of water droplets and ice crystals, their growth, and the development of precipitation. Later chapters are on the larger-scale aspects of cloud physics including severe storms, precipitation processes, and fundamentals of radar meteorology.

to do with conventional photographic film. The final sentence is a warning never to look directly into a laser beam. Perhaps there should also have been a suggestion that the budding holographer ought to consult an expert before he purchases any equipment. It is so easy to labour in vain.

A. Thetford

A. Thetford is Lecturer in the Section of Applied and Modern Optics in the Department of Physics at the University of Reading, UK.

Astronomy for the amateur

ASTRONOMY is a subject which lends itself to the lavish illustrator. On the one hand you have the photographs, a plethora of nebulae, galaxies, star fields, planetary surfaces and lunar landscapes; on the other, you have the imaginative artist only too keen to paint what the eye cannot see (or being ever the optimist I should say "hasn't yet seen"). And with figures, scale diagrams of satellite and planetary systems, galactic clusters, binaries, stellar cross-sections, geological and planetological features, the list could be enormous. I'm a great believer in the adage that a good picture is worth a thousand words and it is obvious that many authors of astronomy texts are too. Looking through some old and some not so old books for the astronomically minded layman, one obvious change with time is the ratio between diagrams and text. In the three astronomical 'glossies' I have before me now this ratio seems to be way above 70%. And why not? What an enchanting feast for the eye they are. The best is by Peter Ryan and Ludek Pesek (*Solar System*, Allen Lane: London, £9.95). Ryan's text gives an easily understood accurate and up - to - date account of our knowledge of the Sun, the planets and their satellites. Pesek's paintings are absolutely fascinating, magical insights into Venusian clouds, Saturnian rings, Jovian electrical storms and a host of planetary and satellite landscapes, all with a starkness that is breathtaking. The photographs are well chosen and beautifully reproduced. But special praise must go to the studio (QED) who produced the diagrams; these are superb. This book is an enchanting guide to the interplanetary age.

Dropping the price by a factor of three we have Ian Ridpath's *Stars and Planets* (Hamlyn: Feltham, UK, £2.95), a lavishly illustrated, rather thin, romp through the history of astronomy, the Solar System and the Universe. On a price per page basis, it is comparable to Ryan and Pesek, but I like Ridpath's style. It bubbles along infectiously and makes this book an ideal introduction to the wonders, beauties and new things in astronomy.

My final big book is a revised edition of the *Mitchell Beazley–Patrick Moore Atlas of the Universe* published in 1970 (*The Mitchell Beazley New Concise Atlas of the Universe*; Mitchell Beazley: London, £12.95). The blurb stresses the fact that it is "new" and "completely revised", but on reading the book one gets an impression rather like opening a packet of "new" "improved" soap powder. The contents differ little from the previous. Not of course that this is altogether a bad thing. The 1970 edition was very good, and these good features remain in this new edition: the star maps, the moon maps and the potted descriptions of a host of astronomical objects. The planetary sections have obviously changed the most and they contain results from all the recent space probes. The book is an excellent aid to learning, ideal for the new astronomer and the schoolroom. If you haven't got the first edition then I recommend this book heartily. If you have the first edition, stick to it and save your money.

Staying with the younger reader for a while we have *Astronomy: An Introduction* by Jacqueline Mitton (Faber: London, hardback £6.25; paperback £2.75). This small format book has about 120 pages of text and its audience seems to be scholars taking the Ordinary Level (middle school) Astronomy examination. Its main usefulness seems to be in what it leaves out. Here is what you would need to know to pass the exam—no more, no less—so it is ideal for a busy scholar but is rather skeletal for others.

The plaintive knockings of Walter de la Mare's horseman are echoed in my next two books. As the Earth-bound traveller, or should I say a few of our travellers, call out to the Universe, "Is there anybody there?", Iain Nicolson (*The Road to the Stars*, David and Charles: Newton Abbot, UK, £5.95) encourages us to build spacecraft and go and see, whereas Ian Ridpath (*Messages from the Stars*, Fontana/Collins: London, paperback 95p) is more content to stay put and broadcast our presence and to listen intently for answers or other communications from "out there". Ridpath starts his book by inquiring if life exists elsewhere in space and informing us that "This is the single most important scientific question which we are currently capable of answering, and certainly the most exciting." Well is it? I'm not convinced. It would probably take much more than Little Green Men in Trafalgar Square to shake us from our xenophobic proclivities, and the importance and the excitement of the possibility of there being other peoples than ourselves doesn't seem to be shared by those world scientists intent on the conquest of disease, poverty, famine and war on a planet whose resources seem to be shrinking as rapidly as its population is exploding.

Ridpath discusses in layman terms the factors that go into the Drake formula (the formula that gives the number of advanced civilisations which exist at the moment and which have the capability for interstellar communication) and the attempts that scientists have already made to find extraterrestrial life, both by experimentation on Mars and by using radio telescopes to listen out. The book considers the humanisation of space and the concepts of space colonies, the message we expect others to send to us, how we would communicate, the consequences of contact, and the possibility that we have already been visited. I found the book a most enjoyable read and a commendable starting point in this engaging subject.

Nicolson's approach is less partisan than Ridpath's. He seems to aim more at the dedicated amateur astronomer than the "man in the street". It is a book which, with exemplary clarity of presentation, brings the reader to and often beyond the frontier between space science and science fiction. Nicolson is discussing star travel, the human race colonising the galaxy. He answers such questions as what spaceships will we use?, "how will they be propelled?", "how long will it take us?", "is it worth it?", and "when will we be ready to go?" Section headings such as "The consequences of contact", "Relativistic starships", "Suspended animation—The practicalities and prospects", "Spinning black holes", "The laser photon sail", "Time dilation", and "The roads to the planets", reveal some of the many feasts that lie in store for the reader. This is an eminently sensible book in a field which is often a happy breeding ground for the over-imaginative. It is a clear, considered scientific exposition of the problems and possibilities of stepping out into the reaches of space. I was impressed. But still the nagging possibility remains that there is no-one out there—no aliens to visit, no reasons to go. What happens if after shouting out our presence, returning to the words of de la Mare, "the silence surged softly backward". I think that realising we are alone would be as disturbing as realising we are not.

Finally we have two books for the telescope owners. I need say very little about Jack Newton's book, *Deep Sky Objects: A Photographic Guide for the Amateur* (Gall Publications: Toronto, hardback £5; paperback £3), other than if you enjoy looking through a telescope, get it immediately. It is a superb practical guide for finding the Messier objects and some of the more interesting of the NGC objects. It contains clear finder charts for all of them and also photographs of each object taken with the author's 12.5-inch Newtonian telescope. Not only are you told where and when to look you are shown what to expect. All astronomers should say a big thank you to Jack Newton for making their telescope time more productive and more enjoyable.

Using the Telescope, by J. Hedley Robinson (David and Charles: Newton Abbot, UK, £4.95) is a different matter. I will agree with the author that a book in which the amateur observers could find "comprehensive instructions for the proper care and maintenance of their telescopes, together with explicit explanations of correct observational techniques for all celestial bodies that they are likely to be interested in" would be extremely useful. Unfortunately the book under review isn't it. Robinson doesn't go far enough. The budding astrophotographer is told next to nothing about the science of photography and is fobbed off with the 'trial and error method'. The section on telescope mounting is complicated by a lack of diagrams and by mislabelling the two that are given. When it comes to observational details our appetites are wetted and then we are left up in the air. I'll give you a typical example: "Since then many TLPs have been recorded in a number of craters, both inside and out"—we aren't told which craters. The spectroscope "is equipped with one or more prisms, set at suitable angles for the light to pass through each in succession," but we are given no hint as to what the angles might be or what prisms to use. I think the amateur observer would do much better by saving a bit more money and buying *Astronomy: A Handbook*, edited by G. R. Roth (Springer: Berlin, 1975).

David W. Hughes

David W. Hughes is Lecturer in Astronomy and Physics in the Department of Physics at the University of Sheffield, UK.

Portrait of five heroes

This Wild Abyss: The Story of the Men Who Made Modern Astronomy. By G. E. Christianson. Pp. 461. (Free Press/Macmillan: New York; Collier Macmillan: West Drayton, UK, 1978.) £9.75.

WHAT a pity! as Sir George Sitwell was fond of remarking: such a wasted opportunity. It is a long time since a general book on the history of astronomy was published and it will be some years yet before the new scholarly history (sponsored by the IAU), now in preparation, is before us. Although one's initial expectation that the "makers of modern astronomy" might include such figures as Hubble and Shapley is proved mistaken, a sound survey of the history of astronomy to Newton would be worth having as so much new work has appeared in recent years. There has been the debate about megalithic observatories, many exciting discoveries made about late Islamic astronomy by E. S. Kennedy and others and the outpourings associated with the anniversaries of Copernicus and Kepler, not to mention whole new worlds of scholarship devoted to Galileo and Newton. A new survey of early astronomy could be both more technically competent and more rich in content, as well as more vivid in its discussions of problems, than anything that has appeared yet. Mr Christianson, however, has only had a slight success in releasing himself from a familiar and by now dated pattern.

He makes no claim to be a technical historian of astronomy, which is fair enough; his chief aim has been to write biographies of five great figures: Copernicus, Brahe, Kepler, Galileo and Newton. But he writes, as perhaps he could not but do, about a good deal else including Greek astronomy and medieval civilisation. A general history (even by a non-specialist author) should get the broad historiography and the basic facts right. Mr Christianson tells us that Ptolemy's orbital elements "did not fit comfortably into" the crystalline spheres of Aristotle "and whether or not Ptolemy even believed in such spheres is not known; they receive no mention in his writings". Not so; solid spheres figure prominently in Ptolemy's *Planetary Hypotheses* and are indeed mentioned occasionally in the *Almagest* itself (see O. Pedersen, *Survey of the Almagest*, 1974, 167, 391–7).

Mr Christianson's whole discussion of ancient astronomy is impaired by his failure to grasp the point emphasised seventy years ago by Pierre Duhem that the Greek astronomer was a mathematician, not a philosopher; and correspondingly that it is impossible to appraise the Copernican revolution properly without first seeing the significance of his opposite position that mathematics, far from merely saving the appearances, is an essential key to physical reality. Mr Christianson seems unfortunately to be wholly unaware of the writings of Duhem—widely regarded as providing the basis for the historiography of medieval science as it has flourished during this century—and only ignorance, again, can account for his extraordinary statement that "the study of the Middle Ages" has "until rather recently languished in our institutions of higher education".

Although the author is more familiar with recent studies of Galileo and Newton, his biographies are still marred by serious mistakes, such as the assertion that Galileo discovered the law of falling bodies by rolling "objects of different weight . . . down an inclined plane . . . keeping time with a specially designed pendulum"; his belief that Descartes proposed to correct *chromatic* aberration by means of aspherical lenses; and his supposition that Newton plunged deeply into the study of the "occult" (Newton did indeed read deeply in alchemical authors and interpret scriptural prophecy, but no-one has yet made him out to be a warlock).

In general, the ideas of established standard works like T. S. Kuhn's *Copernican Revolution* and Giorgio de Santillana's *Crime of Galileo* are fairly represented, and with Newton the author has made use of Frank Manuel's psycho-analytical portrait, Mrs Dobbs's investigation of Newton's alchemy, the publications of R. S. Westfall, and other recent sources. He ends with an exposition, highly laudatory, of Kuhn's *Structure of Scientific Revolutions* with which, he writes, he agrees that "there is nothing absolute in what is called scientific truth", that is, a statement is true so long as we do not suppose it false.

Mr Christianson has no strong thesis of his own, unlike Arthur Koestler whose *Sleepwalkers* rightly aroused so much interest a few years ago (his ideas too are reflected in this book). Rather, Mr Christianson has attempted to synthesise recent writing in the history of science and particularly the interpretation of the Scientific Revolution. If he is not fully in control of his material this is in part because the history of astronomy has become—largely through the leadership exercised by Otto Neugebauer and his students—a highly technical subject, or rather one should say has been restored to its position as a highly technical subject.

In the personal aspects of his biographies Mr Christianson is on smoother ground, and he shows skill in bringing out the characters and intellectual qualities of his subjects in broad terms. If he sometimes stresses the melodramatic—Tycho's metal nose, Galileo's bastard daughters, Kepler's difficult mother and Newton's neuroses—this is what others have done before, including Koestler. For a philosopher like Galileo to have a mistress, and for a mathematician like Newton to have died a virgin is equally newsworthy. More seriously Mr Christianson presents a reasonably coherent and intelligible, if occasionally flawed portrait of his five heroes and conveys the integrity of the epoch that began with Copernicus and ended with Newton even if (as in any popular account) subtle nuances are absent.

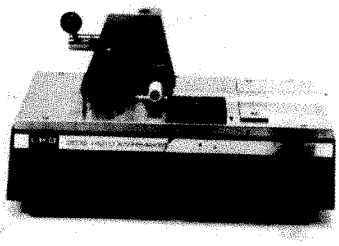
A. Rupert Hall

A. Rupert Hall is Professor of the History of Science and Technology at Imperial College, University of London, UK.

newly on the market

Knifemaker. LKB. The LKB histo knifemaker, the LKB 2078, quickly and routinely produces glass knives either 25 mm or 38 mm cutting-edge length using the 'Ralph knife' principle. Used in existing rotary or base-sledge microtomes, these reproducible, low-cost glass knives will produce large area, high quality, thin sections from either plastic- or paraffin-embedded specimens. The resulting improvement in resolution from the light microscope reveals wide new research and routine application areas in the histology laboratory.

Circle No. 31 on Reader Enquiry Card.



The LKB knifemaker

Environmental air monitor. Applied Science. The Bendix flasher has been introduced by Applied Science for environmental air monitoring by gas/chromatography. Volatile organics in environmental air are readily concentrated for GC analysis by pumping air through small packed adsorbent tubes. These organics can then be analysed by thermally desorbing them directly in a GC column with the Bendix flasher. Sub-p.p.b. range detectability of organics is possible. The flasher is ~0.5 cu ft and can be connected to any gas chromatograph. A portable air sampling pump, which attaches to the clothing of the user, is one of several accessories.

Circle No. 32 on Reader Enquiry Card.

Portable welding unit. British Rototherm. The 'little torch', miniature welding torch, introduced by British Rototherm can now be supplied as a complete kit comprising the torch, hoses, regulators, five tip sizes, goggles, spanners and trolley.

Circle No. 33 on Reader Enquiry Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.

X-ray energy spectrometer. Kevex. Nondestructive, non-contact, rapid multi-element analyses are performed with the Kevex 0750 X-ray energy spectrometer. With the 0750, solid, liquid or granular specimens may be rapidly analysed and compared with production control criteria. Analysis range: p.p.m. to 100% for most elements of atomic number 11–92 can be accomplished in minutes.

Circle No. 34 on Reader Enquiry Card.

Refrigerator incubator. Forma. A general purpose refrigerator incubator designed specifically for controlled temperature storage in the laboratory is now available from Forma Scientific. The unit is available with either a variable temperature range of 0–+60 °C, or factory set at +4 °C. Both models deliver dependable ±0.5 °C temperature control in a 17 cu. ft stainless steel cabinet insulated with 2″ of foamed-in-place urethane. Standard features include independent adjustable safety control with audible and visual alarm, door-ajar warning light with automatic blower cutoff, and automatic condensate removal.

Circle No. 35 on Reader Enquiry Card.

Ultramicrotome. LKB. The LKB Ultrotome V has greatly improved specifications and ergonomic lay-out of controls, a moveable microscope and click-stop (0.1 μm step) and macro (1 μm step) knife stage advance for serial thin and semi-thin sections. Section thickness and specimen approach are clearly and easily viewed using the single pre-positioned lighting system. The compact control unit is separate from the microtome unit thus allowing rapid, accurate changes to be made of all sectioning parameters during sectioning.

Circle No. 36 on Reader Enquiry Card.

Scalar irradiance meter. Biospherical. The QSL–100 is a sensitive new instrument which allows the accurate measurement of the total amount of light photosynthetically active in underwater and dry applications, from culture vessels to rain forests. Easily portable, the QSL–100 uses a solid Teflon sphere, 2 cm in diameter, optically connected to a hand-held detector, filter and amplifier assembly giving it an equal quantum response over 400–700 nm. The QSL–100 reads out the total number of photosynthetically active photons at the meter's tip when inserted into incubators or immersed in cell suspensions.

Circle No. 37 on Reader Enquiry Card.

Automatic conversion device for protein sequencers. Sequemat. The Sequemat P-6 Auto Converter is an in-line system for the conversion step of the Edman degradation. ATZ samples from each cycle collect in a reaction cell, convert to the PTH derivative and are delivered to the sequencer fraction collector. The P-6 unit has its own programmer for optimal flexibility of all functions. Benefits include improved yields of PTH derivatives and reduced operator error.

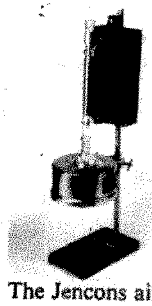
Circle No. 38 on Reader Enquiry Card.

Underwater acoustic television system. EMI. A portable acoustic television system has been developed by EMI Electronics which makes it possible to view objects underwater in conditions of zero visibility. With this 200-line scan system, the object to be investigated is irradiated with ultrasonic energy from an array of transducers arranged around the camera lens, and the reflected energy is focused on the face-plate of an image converter tube which converts the received signal to a visual display on a television monitor screen. It is also capable of locating cracks and voids on, or beneath, the surface of underwater structures. The underwater camera in its housing measures approximately 1,000 mm long by 250 mm in diameter, and weighs 20 kg. The system has a viewing range of up to 10 m and is capable of working at a depth of 300 m.

Circle No. 39 on Reader Enquiry Card.

Reflux condenser. Jencons. The airflux is a simple air-cooled reflux condenser which is as efficient as any normal water cooled condenser, but without the risks of flooding and its attendant fire risk, particularly when in use with solvents. The airflux needs no coolant water, and there are no parts to corrode or wear out. It has been operated for 1,500 h at laboratory temperatures up to 37 °C. Over this period there was no measurable loss of water from the boiling flask. Airflux can be used for distillation.

Circle No. 40 on Reader Enquiry Card.



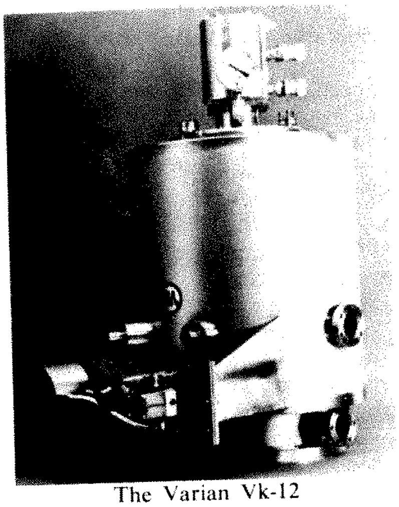
The Jencons airflux

Gas chromatograph. Packard. The Packard range of gas chromatographs now includes the 430 series GC with built-in dual integrator and printing facilities. Processor capacity has been expanded to perform independent dual-channel integration of the detector signals and to produce a complete analysis report via a built-in printer. When combined with the multi-dimensional switching system module, 18 complete GC programs of 15 time-based instructions each can be stored and executed at the touch of a button. The column switching technique employs solenoid valves which alter pressures at various points in the chromatographic system to change flow rates and reverse flow directions, thus eliminating leakage and overcoming the temperature limitations of conventional valves. The system has interchangeable analytical modules. Injection ports, columns and detectors are combined into one integral module, which can easily be changed to suit a particular analysis.
Circle No. 41 on Reader Enquiry Card.

Screening test for blood lead. MSE. An instrument is now available with which a blood sample can be checked in about 10 s to give an indication of the presence of lead in the body. The instrument, the ESA model 4000, uses fluorimetry to measure the amount of zinc protoporphyrin in a drop of blood (about 30 μl). Using the instrument, hundreds of blood samples can be checked in a day. The model 4000 is portable, and extremely easy to operate. The presence of lead in the environment during the analysis cannot affect the result.
Circle No. 42 on Reader Enquiry Card.

Liquid scintillation counter. Packard. A computer-controlled liquid scintillation counter where the only user interaction is loading and unloading trays of samples has been introduced by Packard. Automatic efficiency correlation ensures that all samples are measured with maximum Figure of Merit, plus optimum radionuclide separation in dual-label counting. The 15 different measuring programs are stored on a flexible diskette. Program selectors are clipped to the face of the 'servo-tray' by the user to ensure that correct parameters are retrieved from the diskette to measure the batch of samples. There are 9 trays, each with a capacity of 50 samples. Correlation curves are plotted, using a quench indicating parameter of external standard channels ratio, or a number derived from the measurement of an external standard source. An active parameter control allows modification to the parameters of a sample being measured to determine the best channel settings.
Circle No. 43 on Reader Enquiry Card.

Cryopump with integral valve mechanism. Varian. This is the first cryopump to incorporate a built-in valve mechanism designed specifically to meet the requirements of 'state-of-the-art' vacuum processes. Called the VK-12, the cryopump combines the performance of larger diffusion pump systems with the contamination-free operation of smaller ion pumps. It uses a unique integral swing gate valve mechanism that permits the seal plate to swing completely clear of the pumping orifice. A valve actuator controls the force required to achieve position sealing by swinging the seal plate into position and raising it against the sealing surface.
Circle No. 44 on Reader Enquiry Card.



The Varian Vk-12

Flatbed chart recorders. Bryans Southern. Bryans Southern Instruments have extended the range of flatbed chart recorders with their BS900 series of multi channel recorders. These are available in either three channel or four channel versions. Input amplifiers for each channel can be selected from modules having 12 or 18 voltage ranges or a 24 range module with 12 voltage and 12 current ranges; the chart speed module has 16 ranges. The recorder pens are rechargeable fibre tipped, write over the whole 250 mm width of the chart paper, and have a dynamic response of 0.65 s for full scale deflection.
Circle No. 45 on Reader Enquiry Card.

Laboratory furniture. Gallenkamp. A combination of traditional and modern timber-based materials, Gallenkamp System M furniture is robust, hard-wearing and attractive in appearance. The modular units are versatile and freely interchangeable. Most of the units are designed so that they can be packed flat. Modules available incorporate benches with a choice of drawer, cupboard or tray under storage units, sinks, mobile demonstration bench units and a fume cupboard.
Circle No. 46 on Reader Enquiry Card.

Dissolved hydrogen analyser. George Kent Electronic Products have introduced a dissolved hydrogen analyser, model 6421, to measure the amount of hydrogen in boiler steam. The new instrument gives advanced warning of boiler tube breakdown so that the boiler workload can be rescheduled to avoid failure. It works by measuring the amount of hydrogen dissolved in water condensed from the boiler steam. The instrument employs katharometric principles, and features a built-in power supply, automatic temperature compensation, dual ranges of 0–20 and 0–200 μg l^{-1}, a simple zero check which does not affect the sample flow and an adjustable level alarm signal output. It is unaffected by additives or contaminants.
Circle No. 47 on Reader Enquiry Card.

Monochromator. Jobin-Yvon. Jobin-Yvon have announced a new low-cost quarter-metre monochromator, the model H-25. This is a compact, lightweight and versatile instrument which can cover a very wide spectral range (from 180 nm in the near UV to 30 μm in the far IR) using high-efficiency holographic gratings. The gratings are easily interchangeable on pre-focused mountings. The optical arrangement is based on a Czerny-Turner mounting and uses two plane and two concave mirrors. The resolution is 0.3 nm at 500 nm while the dispersion is 3 nm mm^{-1}, with a 1,200 lines mm^{-1} grating.
Circle No. 48 on Reader Enquiry Card.

Protease detection kit. Bio-Rad. Bio-Rad's protease detection kit provides a convenient way to measure the activity of serum proteases, or of other proteases such as trypsin, α-chymotrypsin and pronase. When dissolved, tablets from the kit form an agar gel containing a protein preparation which gives it a turbid appearance. The sample to be assayed is placed in a well and diffuses into the gel forming a clear ring where the protein is digested. Proteolytic activity can then be determined very simply from the ring diameter, using guides provided in the kit.
Circle No. 49 on Reader Enquiry Card.

Electrophoresis power supplies. Buchler. Buchler Instruments has introduced two new DC power supplies designed for immuno-, paper and thin layer electrophoresis techniques. Each unit features easy to read, oversized meters and a single control for varying the output. One unit has ranges of 0–350 VDC, 0–100 mA and the other unit provides 0–1,000 VDC, 0–200 mA. Both of these units have dual output jacks so that more than one chamber may be operated at the same time.
Circle No. 50 on Reader Enquiry Card.

THE OPEN UNIVERSITY
FACULTY OF SCIENCE
Course Co-ordinator in Physics

Applications are invited for the permanent post of Course Co-ordinator in the Physics Discipline.

The main duties of the post are to provide a range of academic, administrative and editorial services to course teams producing multi-media undergraduate courses in Physics. Applicants should have a first degree in Physics or a relevant subject, and an interest in administration.

Appointment will be made within the Course Co-ordinator salary scale £3,384 to £4,882 per annum with U.S.S benefits.

Application forms and further particulars are available from The Recruitment Office (JD1978/4), The Open University, P O Box 75, Walton Hall, Milton Keynes MK7 6AL, or by telephone from Milton Keynes 63404. there is a 24 hour answering service on 63868.

Closing date for applications January 3, 1979. 8706(A)

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF THERAPEUTICS AND CLINICAL PHARMACOLOGY

Applications are invited from appropriately qualified scientists for a

SENIOR LECTURESHIP
in
THERAPEUTICS AND CLINICAL PHARMACOLOGY

The candidate will be expected to be an expert in pharmacokinetics and microanalytic techniques of measuring plasma drug levels and to work with medically qualified colleagues

The Department has beds in the Queen Elizabeth Hospital, Birmingham For a suitably qualified candidate the post may be associated with an honorary appointment as a Consulting Clinical Pharmacologist.

Salary in the range for non-clinical academic staff £7,506 to £9,263 per annum, plus superannuation.

Applications naming three referees, should be sent to the Assistant Registrar, Medical School, University of Birmingham, Birmingham B15 2TJ, by January 8, 1979

Further particulars may be obtained from Professor O. L Wade, Department of Therapeutics and Clinical Pharmacology, Clinical Research Block, Queen Elizabeth Hospital, Birmingham B15 2TH. 8738(A)

CHROMATIN RESEARCH
BIOPHYSICS LABORATORIES
PORTSMOUTH POLYTECHNIC
RESEARCH ASSOCIATE

required for two years initially, to work in Dr E. M. Bradbury's research group. The structure and function of chromatin are studied by both physical and biochemical methods The group has a high field N M.R spectrometer and is actively engaged in neutron and X-ray diffraction work. Experience of one of these techniques, although desirable, is not a prerequisite for appointment. However, knowledge of, and some research experience in general biochemical techniques is expected The successful candidate's project will depend on his/her interests and background.

Salary scale; £3,510 to £3,607 per annum.

Application forms and further details may be obtained from the Staff Officer, Portsmouth Polytechnic, Alexandra House, Museum Road, Portsmouth PO1 2QQ, to whom completed applications should be returned by December 30, 1978, quoting reference S54 8709(A)

DEPARTMENT OF HEALTH
NATIONAL HEALTH INSTITUTE
Wellington, New Zealand

Applications are invited from medical mycologists or science graduates with experience in medical mycology for a senior position in the Mycology Reference Laboratory.

The unit is responsible for the investigation of fungal infections, the identification of fungi referred from New Zealand and South West Pacific laboratories, for a fungal type culture collection and for the training of mycologists

The Mycology Reference Laboratory is used by medical laboratories throughout New Zealand as a source of reference and diagnostic service for fungal infections. It has working association with dermatologists, veterinarians, veterinary and university departments and overseas laboratories which specialise in mycology Qualifications desired are a medical or science degree with special training and experience in medical mycology Salary: Medical Graduate with science qualifications NZ$19,621 to NZ$25,364. Science Graduate NZ$10,672 to NZ$18,377 Each according to qualifications and experience. The post carries all privileges of State Services employment Applications should be forwarded with copies only of testimonials to The Chief Migration Officer, New Zealand House, Haymarket, London SW1Y 4TQ.

You should quote: IMM7/327/18

Assistance with fares and forwarding of baggage to New Zealand Closing date for applications: January 13, 1979 8690(A)

National Research Council Canada   Conseil national de recherches Canada

ASTRONOMER

The Herzberg Institute of Astrophysics has an opening for an **astronomer** at its **Dominion Astrophysical Observatory, Victoria, British Columbia.** The incumbent will be expected to undertake independent research in observational astronomy.

QUALIFICATIONS:

Candidates should have a Ph.D. or equivalent degree in astronomy or in a related discipline with several years of experience in astronomical research. Preference will be given to applicants with experience in extragalactic astronomy.

Knowledge of the English language is essential for this position.

Salary will depend on qualifications and experience.

Apply in writing giving complete details of education and experience to:

NRC

The Employment Officer, National Research Council of Canada, Ottawa, Ontario, Canada K1A OR6. Include a list of publications and the names of referees from whom confidential evaluations can be sought. In reply please quote HIA-56. 8702(A)

KING'S BUILDINGS
WEST MAINS ROAD
EDINBURGH EH9 3JS

A BIOCHEMIST

with relevant physiological experience is required by the Reproductive Physiology Department at the above Centre, to undertake work in the field of reproductive physiology and biochemistry of the male Initially the appointee will be expected to participate in comparative investigation of the function of fowl and turkey spermatozoa associated with the development of techniques of semen storage above and below zero degrees centigrade A general interest in the function of the organs in the male concerned with reproduction and spermatozoa would also be desirable, relevant to maintaining the fertility of the male under different management systems In this respect facilities exist for collaborative work involving endocrinology and nutrition.

Qualifications—First or upper second class honours degree, at least two years' relevant post-graduate experience and, preferably, a Ph.D.

Salary—In scale £4,101 to £5,448 at H S C level and £5,154 to £6,898 at S.S.O level Entry at the higher level requires at least four years' post-graduate experience Non-contributory superannuation scheme. 22 days annual leave plus 10½ public/privilege holidays

Application forms can be obtained from the Secretary at the above address, these should be completed and returned to him not later than December 29, 1978. 8749(A)

THE UNIVERSITY OF BRITISH COLUMBIA

DEPARTMENT OF CHEMISTRY

ASSISTANT PROFESSORSHIP

Applications are invited from well qualified candidates for a position at the rank of **Assistant Professor** which will become vacant on June 30, 1979. Persons with research and teaching interests in one of the following areas will be given preference: **Organic Chemistry** including **Biological Organic Chemistry, Polymer Chemistry,** and **Analytical Chemistry.**

Applications consisting of a curriculum vitae, a list of publications and the names and addresses of three referees should be sent to the undersigned before March 31, 1979. This position is open to both male and female applicants.

Professor Charles A. McDowell

AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for appointment to the following

RESEARCH SCHOOL OF PHYSICAL SCIENCES

DEPARTMENT OF NUCLEAR PHYSICS

FELLOW/SENIOR RESEARCH FELLOW/RESEARCH FELLOW/POSTDOCTORAL FELLOW

(3 posts)

The Department, with an academic staff of eighteen headed by Professor J O Newton, carries out research mainly in the field of nuclear structure physics but a small group also works in the area of ion-solid interactions Currently the nuclear physics interests are nuclear phenomena at very high angular momentum, measurement of static and dynamic electromagnetic moments, heavy-ion transfer reactions and nuclei far from the stability line The ion-solid interests are in beam foil spectroscopy, channelling and radiation damage The major accelerator is the 14UD pelletron tandem (14 MV terminal) An Enge split-pole spectrometer, equipped with focal plane detector, is available The Department hopes to be able to fill a tenured position (Fellow) and non-tenured positions (Postdoctoral Fellow, Research Fellow, Senior Research Fellow) in the area of nuclear physics; only applicants for non-tenured positions will be considered for the ion-solid field

CLOSING DATE **FEBRUARY 16, 1979.**

SALARIES Salary on appointment will be in accordance with qualifications and experience within the ranges Fellow $A17,694 to $A23,704, Research Fellow $A15,179 to $A19,813, Senior Research Fellow $A21,201 to $A25,289, Postdoctoral Fellow $A15,179 to $A19,813 per annum Current exchange rates $A equals $US1 13 £0 58

TENURE Appointment as Fellow is five years in first instance with the possibility, after review, of reappointment to retiring age 65 years, as Senior Research Fellow/Research Fellow normally for three years in the first instance with the possibility of extension to five years, as Postdoctoral Fellow for a maximum of two years

OTHER CONDITIONS Reasonable appointment expenses are paid Superannuation benefits are available for applicants who are eligible to contribute Assistance with housing is provided for an appointee from outside Canberra

The University reserves the right not to make an appointment or to make an appointment by invitation at any time

Prospective applicants should obtain further particulars from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF

8748(A)

UNIVERSITY OF SALFORD

DEPARTMENT OF BIOLOGY

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for a Postdoctoral Research Fellow sponsored by the Science Research Council, to investigate the respiratory/cardiovascular function in terrestrial vertebrates under the supervision of Dr J H Brakenbury The appointment is tenable for three years commencing as soon as possible

Commencing salary within the range £3,883 to £4,328 per annum.

Application forms obtainable from the Registrar, University of Salford, Salford M5 4WT (Tel 061-736 5843, Ext. 215) to whom completed applications should be returned not later than Friday, December 22, 1978 quoting reference B/85/N. 8696(A)

UNIVERSITY OF IFE NIGERIA

Applicants are invited for the post of

SENIOR LECTURER

IN DEPARTMENT OF BIOCHEMISTRY

Salary scale N7,764 to N8,724 p a (£6,161 to £6,923 p a. sterling) (£1 sterling=N1 26) There may be supplementation of salary by £2,892 p a (sterling) for married appointees or £726 p a (sterling) for single appointees and provision of children's education allowances and holiday visit passages Fringe benefits include pension scheme or contract addition of 25% of salary (partly taxable), family passages, baggage allowances, car and housing allowances, various allowances

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent to Registrar, University of Ife, Ile-Ife, Nigeria by January 4, 1979

Applicants resident in the UK should also send one copy to the Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT Further details may be obtained from either address 8761(A)

THE NORTH E WALES INSTITUTE OF HIGHER EDUCATION

Clwyd Area Health Authority and the North E Wales Institute

RESEARCH TECHNICIAN—ANAESTHESIA AND IMMUNOCOMPETENCE

A Research Technician (Grade T2, Salary £3,369, Point 15—inclusive) is required for an initial two-year study of the effects of anaesthesia on lymphocyte function. This is a collaborative project between the North E Wales Institute and the Department of Anaesthetics, Maelor General Hospital, Wrexham

Applicants should be experienced in cell biology, immunology, biochemistry or haematology

Applications by letter (no forms) to the Institute Registrar, North E Wales Institute of Higher Education, Kelsterton College, Connah's Quay, Deeside, Clwyd Tel· Deeside 817531, by December 15, 1978 8755(A)

UNIVERSITY OF GLASGOW

INSTITUTE OF VIROLOGY

SENIOR LECTURESHIP IN VIROLOGY

Applications are invited for a Senior Lectureship in the Department of Virology at the Institute of Virology Tenable from March 1, 1979, or as soon as possible thereafter. The Institute, which is heavily engaged in biomedical research, comprises both the University Department of Virology and the Medical Research Council Virology Unit, under the direction of Professor J H Subak-Sharpe The successful applicant would have considerable opportunity for interaction and collaborative work with the interdisciplinary research staff In addition to teaching duties to undergraduates in B Sc and M B , Ch B courses, the applicant would have joint responsibility for the Diagnostic Virology Service to the Western Infirmary and Gartnavel Hospital Applicants should be medically qualified and have suitable specialist experience.

Salary will be according to placement on the University scale for clinical teachers The maximum of the Senior Lecturers' scale is £12,084

Further particulars may be obtaine from the Secretary of the Universit Court, (Room 18), University of Glasgow, Glasgow G12 8QQ, with whom applications (12 copies), giving th names and addresses of three referee should be lodged on or before Januar 10, 1979.

In reply please quote Ref. No 4317ML 8608(A)

THE UNIVERSITY OF NEWCASTLE

Newcastle, N S.W., Australia

POSTDOCTORAL RESEARCH FELLOW

DEPARTMENT OF MATHEMATICS

Field Renormalisation Group Theory in Statistical Mechanics

Project. The successful candidate will be familiar with the theory of Renormalisation Group methods and their application to Critical Phenomena, and will work on a project entitled "Investigation of non-translationally invariant lattice models by Renormalisation Group and Peturbation Expansion methods". In this project a study will be made of magnetic surfaces and films, polymer films and surfaces, percolation at a surface and in confined geometries, and related problems.

Qualifications A Ph D or the equivalent, preferably with some postdoctoral experience in the appropriate field.

Salary. Australian $A13,343 to $A16,882 per annum, plus travel allowance of up to $A2,000

Tenure. The appointment will be for one year in the first instance, with the prospect of renewal for two further years

Further scientific details of the project may be obtained from the Head of Department, Department of Mathematics, University of Newcastle, N S W., Australia, (Assoc Prof A J Guttmann)

Applications giving relevant personal and professional details, and the names of at least three referees should be sent to·

Vice-Principal,
University of Newcastle,
Newcastle, N S W 2308,
Australia 8674(A)

UNIVERSITY OF EAST ANGLIA

Norwich

HYDROLOGY AND FRESHWATER ECOLOGY

Posts are available for a Senior Research Associate (postdoctoral) and two Research Associates, (postgraduate) to assist in a major study of water chemistry, plankton ecology, and palaeolimnology of a part of the River Bure and its ten associated broads The senior post is for a hydrologist, preferably with experience of tracer studies, who will establish the patterns of water movement in the tidal river and broads and who will also be responsible for the day-to-day administration of the project The research associates will be graduates in environmental or biological sciences and will be concerned with chemical and biological aspects It is intended to produce a predictive model of the behaviour of the system which will aid in the eventual restoration of this very eutrophicated waterway Salary will be on scale 1A (senior post) £3,883 to £6,555 and scale 1B (research associates) £3,384 to £4,882 Applicants, who should be able to drive, should write to Dr Brian Moss, School of Environmental Sciences, University of East Anglia, Norwich NR4 7TJ, giving a curriculum vitae and quoting two immediately contactable referees, by December 15, 1978 8688(A)

RESEARCH FELLOW

A vacancy exists for the above post in the Department of Medical Cardiology, Royal Infirmary, Glasgow G4 0SF

The candidate will be mainly involved in developing and extending techniques to study various aspects of lipid and myocardial metabolism

The candidate will also be responsible for supervising the laboratory, which has excellent research facilities and has a staff comprising a research assistant and three technicians

Applications to Professor T D V Lawrie, at the Department of Medical Cardiology, from whom a detailed job description may be obtained

8701(A)

Rheumatism Research

Biologist/Biochemist

We require a post-doctoral scientist to lead a small established biological research group within the rheumatism research area in our laboratories in Nottingham. The group concentrates on investigating the biochemical and immunological aspects of chronic inflammatory disorders with the objective of developing new and more effective drugs

Applications are invited from graduates (men and women) who, ideally, have a first degree in Biochemistry or Cell Biology, a Ph.D in an appropriate subject and preferably with one or two years' relevant post-doctoral experience A knowledge of immunology would be an added advantage

This is an excellent opportunity for a person with initiative and the ability to motivate others to participate in an expanding area of our research

Company benefits include profit sharing and staff purchase privileges Generous help with relocation to the area is available.

Please send for application form to T. W Flower, Employment Manager (Technical),

The Boots Company Limited,

Station Street, Nottingham, NG2 3AA

8778(A)

UNIVERSITY OF NAIROBI

KENYA

Applications are invited for the post of PROFESSOR in the DEPARTMENT OF FORESTRY. Applicants should be holders of a basic degree in Forestry plus a Ph D in one of the professional disciplines of forestry in Silviculture, or Mensuration or Forest Engineering or Wood Technology The applicants should have several years' teaching experience at University level and several years' research in forestry science as supported by scientific publications Applicants with Masters degrees and several years' teaching and research experience at University may also be considered Appointee will be expected to teach undergraduate students in their particular field of interest in Forestry Science, to develop research, and to guide postgraduate students for higher degrees in Forestry Science Initial appointment will be on a two-year contract which can be renewed by mutual agreement.

Salary scale· K£4,632 to K£5,562 p a (K£1=£1 37 sterling) The British Government may provide salary supplementation of £5,796 p a (sterling) for married appointee or £4,182 p a (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages Family passages; S S S F or F S S U, non-contributory medical scheme; subsidised housing/housing allowance

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Registrar (Recruitment and Training), University of Nairobi, P O Box 30197, Nairobi, Kenya by January 3, 1979 Applicants resident in the U K should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT Further details may be obtained from either address

Department of Health and Social Security, London

Pharmacists/Biologists

...an important role in medicinal safety

The scientists appointed will join the medical and scientific secretariat serving the Committee on Safety of Medicines. They will assist senior medical staff in evaluating the safety and efficacy of new drug substances on which applications have been submitted for clinical trial certificates or product licences. Ample opportunity will be given to keep abreast of developments in this specialised area

Candidates, normally aged under 30, must have a good honours degree or equivalent in a biological science coupled with experience of pharmacology or toxicology. Preference will be given to candidates with a higher degree or to those who have had relevant experience in the pharmaceutical industry

Appointment as Higher Scientific Officer (£4560–£5910) or Scientific Officer (£3300–£4880) according to qualifications and experience. Promotion prospects Non-contributory pension scheme. *Please quote ref: SB/4/KB.*

■ *For application form see below*

Department of Health and Social Security, Middlesex

Pharmacist/Chemist

The British Pharmacopoeia Commission is responsible for all standards published in Britain for substances and articles used in human and veterinary medicine The pharmaceutical tests and methods of analysis included in their publications have largely been evolved in the Pharmacopoeia laboratory, which is equipped for a range of spectroscopy, chromatography, classical analysis and physical testing

As a member of a team of scientists, located in Canons Park, Middlesex, the pharmacist chemist appointed will critically examine proposed specifications for medical substances, prepare reports and make recommendations, maintain quality control measures for medicinal chemical reference substances used in assays and tests of the British Pharmacopoeia, and assist in the development of suitable analytical methods for routine quality control of pharmaceuticals In addition, the successful candidate will supervise and train junior staff in the team, and where necessary attend meetings to present reports and recommendations to the appropriate committees responsible for approving standards for publication

Candidates, normally aged under 30, should preferably have an honours degree or equivalent in chemistry or pharmacy. At least 2 years postgraduate experience of quality control of pharmaceuticals or the analytical techniques used in the laboratory is essential.

Appointment as Higher Scientific Officer (£4375–£5725) with starting salary according to qualifications and experience Promotion prospects. Non-contributory pension scheme. *Please quote ref. SB/12/KD*

For further details and an application form (to be returned by 5 January 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours) *Please quote appropriate reference.*

Science Group CIVIL SERVICE

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

(University of London)

Keppel Street, WC1E 7HT

DEPARTMENT OF HUMAN NUTRITION

LECTURER IN NUTRITION IN DEVELOPING COUNTRIES

Applications are invited for the above post, for which the main responsibilities will be —

(i) to provide advice, as required, on the nutritional aspects of projects and programmes in developing countries, and, in consultation with other members of the department and of the School, to formulate the appropriate nutritional inputs into such programmes,

(ii) to assist, both in the UK and overseas, in the training of nutritionists and nutrition field members,

(iii) to advance the subject by research.

Applicants should be medically qualified, should have experience of field work in developing countries, and should be freely available for overseas travel

The appointment will be initially for a period of 3 years, and will be in the salary range for clinical university lecturers (£4,986 to £7,393 and £354 London Weighting)

Application forms, which should be returned by January 31, 1979, and further information are available from F C Ball, Assistant Secretary 8763(A)

UNIVERSITY COLLEGE OF NORTH WALES

SCHOOL OF PLANT BIOLOGY

Applications are invited for the post of RESEARCH OFFICER, financed by the N.E.R.C to undertake research in collaboration with Dr C M Happey-Wood on the physiological ecology of micro-green algae Investigations will involve field work and laboratory studies of the effects of light and temperature on photosynthesis and growth, and of phosphorus uptake and flux in algal cultures under controlled conditions

This is a three-year project, but the appointment will be for one year in the first instance, on the lower portion of the Research and Analogous IA scale, £3,883 to £4,882 per annum

Applications (two copies) giving details of qualifications, age and experience, together with the names and addresses of two referees should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG, from whom further particulars may be obtained

Closing date for the receipt of applications January 2, 1979

Applications are invited for the following posts in the DEPARTMENT OF CROP SCIENCE.—

PROFESSOR— HORTICULTURE OR AGRONOMY

Applications are invited from specialists in Agriculture, Horticulture or Botany who must be holders of a Ph D. either in Agronomy or Horticulture. Candidates should have considerable experience in teaching and research as substantiated by published work. The appointee will be required to undertake academic leadership in the field of Crop Science with regard to teaching and research both at undergraduate and postgraduate level The appointment will be on contract terms

PROFESSOR—CROP PROTECTION IN ENTOMOLOGY

Applications are invited from specialists in Agriculture, Horticulture or Zoology/Entomology who must be holders of a Ph.D. in Agricultural Entomology Candidates should have considerable experience in teaching and research as substantiated by publications in the relevant discipline The appointee will be required to undertake academic leadership in the field of Agricultural Entomology with regard to teaching and research at both undergraduate and postgraduate levels. In addition he/she will be required to lay groundwork in the design and implementation of a postgraduate course in Agricultural Pest Management This appointment will be on contract terms

Salary Scale. K£4,632 to K£5,562 p.a (K£1 equals £1.37 sterling) The British Government may provide salary supplementation of £5,796 p a (sterling) for married appointee or £4,182 p a. (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages Family passages, S S.S F or F.S.S U, non-contributory medical scheme; subsidised housing/housing allowance. Detailed applications (two copies) with curriculum vitae and naming three referees to be sent to Registrar (Recruitment and Training) University of Nairobi, PO Box 30197, Nairobi, Kenya by January 3, 1979. Applicants resident in the U K should also send one copy to Inter University Council, 90/91 Tottenham Court Road, London W1P 0DT Further details may be obtained from either address

8707(A)

Coleg Prifysgol Cymru

THE UNIVERSITY COLLEGE OF WALES

Aberystwyth

DEPARTMENT OF BIOCHEMISTRY AND AGRICULTURAL BIOCHEMISTRY

DEPARTMENTAL SUPERINTENDENT

(Technical Staff Grade 8)

Applicants should have considerable practical experience of the organisation and equipment needs of biochemical or chemical laboratories The person appointed will be responsible for the technical services of the Department and the relevant financial control.

Salary £4,746 to £5,160 per annum (under review).

Further details may be obtained from the Registrar, The University College of Wales, King Street, Aberystwyth, Dyfed SY23 2AX, to whom applicants should apply by letter by January 2, 1979

8677(A)

UNIVERSITY OF GLASGOW

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a Postdoctoral Research Assistant supported by the M.R C. to work with Dr H. G. Nimmo on the purification and regulatory properties of the mitochondrial glycerol phosphate acyltransferase from mammalian liver. Prior experience of working with membrane-bound enzymes would be an advantage

The appointment will initially be for one year, from January 1, 1979, renewable for two further years subject to satisfactory progress.

Salary within range £3,883 to £4,882 on Range 1A of the salary scale for Research and Analogous staff according to age and experience Superannuation Scheme will apply

Applications, with a curriculum vitae and the names of two referees, should be sent to Dr H. G. Nimmo, Department of Biochemistry, University of Glasgow, Glasgow G12 8QQ, by December 22, 1978.

In reply please quote Ref No 4319M.

8641(A)

UNIVERSITY OF ZAMBIA

Applications are invited for the post of

SENIOR LECTURER/ LECTURER

in the
DEPARTMENT OF
LAND RESOURCES SURVEY—
SCHOOL OF NATURAL SCIENCES

Applicants should possess a first degree in Agriculture, Biology, Geography or Geology and preferably a higher degree in Land Resources Survey or an allied field. Appointee will be expected to teach the M Sc programme

Salary Scales Senior Lecturer, K7,608 to K8,106 p a., Lecturer, K4,956 to K7,608 p a (£1 sterling= K1 55.) The British Government may supplement salary in range £2,922 to £4,350 p a (sterling) for married appointee or £930 to £1,968 p a (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages Family passages, superannuation scheme, housing allowance, biennial overseas leave, various allowances.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent to Registrar, University of Zambia, P O Box 2379, Lusaka, Zambia, by January 13, 1979

Applicants resident in the U K should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT Further details may be obtained from either address.

8772(A)

Peptide Chemist

The growing importance of peptides in the search for
medicinal agents has placed a new emphasis on the
development of their large scale synthesis. As a
result of successful research in these laboratories
a position has been created for a
Peptide Development Chemist.
The successful applicant will preferably have several
years post-graduate experience in peptide research
or development. The laboratories are well equipped with all
the modern techniques associated with peptide
synthesis, purification and identification and the successful
applicant should be completely familiar in their use.
Terms and conditions of employment will be appropriate
to this appointment and salary will be negotiable
according to ability and experience plus assistance with
relocation to the Kingston-upon-Hull area
Applicants should write in complete confidence
to Miss N V McGeown, Personnel Officer,
at the address below:
Reckitt & Colman, Pharmaceutical Division,
Dansom Lane, Hull HU8 7DS

Reckitt & Colman

8667(A)

THE ROYAL MARSDEN HOSPITAL

Downs Road, Sutton, Surrey

TECHNICIAN

NUCLEAR MEDICINE DEPARTMENT

Salary
£2,700 to £3,621/£3,285 to £4,188

Technician required to complete a team of three in an in vitro laboratory carrying out mainly routine test involving radioisotopes The work is rewarding and requires an interest in patient contact.

Applicants should have 2 'A' Levels including a science subject and 3 years technical experience or ONC/HND

Application forms from Personnel Department, Royal Marsden Hospital, Fulham Road, London SW3 Telephone 01-352 8171, extn 446.

Closing date December 21, 1978

8764(A)

National Heart and Chest Hospitals

BROMPTON HOSPITAL

JUNIOR MEDICAL LABORATORY SCIENTIFIC OFFICER

required for Histopathology and Haematology Departments Candidates should have either 4 'O' levels (including Mathematics and 2 science subjects) or 2 'A' levels (including chemistry) or a degree

Application form available from Miss J. A Jenks, Personnel Manager, Brompton Hospital, Fulham Road, London SW3 6HP (tel: 01-352 8121, extn 4357).

8765(A)

GRADUATE or Postdoctoral Researc Assistant required for 1½ years in th Department of Microbiology for a M R C. research project on cyto megalovirus immunovirology. Labora tory experience in virology essential Applications, with full curriculum vitae and the names of two referees to the Secretary, Guy's Hospita Medical School, London Bridge SE 9RT quoting Ref. M C.2

8743(A)

UNIVERSITY OF DURHAM

DEPARTMENT OF CHEMISTRY

Applications are invited for a

POSTDOCTORAL SENIOR RESEARCH ASSISTANT

to work on a Ministry of Defenc project involving the evaluation of X ray photo electron spectroscop (E.S.C A.) for materials characterisa tion in collaboration with Dr D. T Clark The work will involve th application of E.S C.A. to a wide rang of problems in the surface characteris tion of materials of interest to th Materials Quality Assurance Directora of the Ministry of Defence. A back ground in either spectroscopy o materials science would be an advan tage. The appointment will be for on year from early in 1979.

Salary in the range £3,883 to £4,63 per annum, plus superannuation

Applications (three copies) should b sent by January 1, 1979 to th Registrar and Secretary, Scienc Laboratories, South Road, Durham DH1 3LE, from whom further particulars can be obtained.

8687(A)

M.R.C. CLINICAL RESEARCH CENTRE
(Northwick Park Hospital)

Watford Road, Harrow, Middlesex, HA1 3UJ

POSTDOCTORAL BIOCHEMIST

A Postdoctoral Enzymologist is required for investigations of the possible causes of perinatal deaths. (Many existing diagnostic categories are inadequate.) The programme would centre on developmental enzymology especially of mitochondrial systems and previous experience in biochemistry of mitochondria is therefore desirable. This appointment will be for three years only.

Salary within the range £4,408 to £6,080 and L.A.

Further details and application form from Mrs J Tucker-Bull, quoting reference 133/1/4267.

Closing date: December 30. 8766(A)

Reckitt & Colman

The recent growth in the research interests of our pharmaceutical division have given rise to a number of vacancies in our Biological Chemistry Department. The activities within this department are wide ranging and include bioanalysis and metabolism studies. These functions play a key role in the discovery and development phases of our drugs.

Biochemists: Drug Metabolism

The positions would suit graduate chemist biochemists preferably with several years relevant experience. The successful candidates will be predominantly involved with the use of radio labelled drugs for the investigation of their metabolic fate in animals and man.

Chemist/Biochemist: Bioanalysis

This position is suitable for a graduate with several years relevant experience or possibly a recently qualified PhD. He/she will assume responsibility for the development of radioimmunoassay techniques for new compounds. Experience of the synthetic problems associated with radioimmunoassay would prove an advantage. Commencing salaries will be negotiable and will reflect the qualifications and experience of the successful applicants. Application forms and further information regarding these posts may be obtained from Miss N.V. McGeown, Personnel Officer at the address below. All enquiries and applications will be treated in strict confidence.

Reckitt and Colman, Pharmaceutical Division,
Dansom Lane, Kingston upon Hull, HU8 7DS.

8693(A)

POSTDOCTORAL POSITION
Insect Biochemistry

Recent Ph.D. with strong background in protein fractionation, enzymology, and/or immunochemistry to study the role of juvenile hormone binding proteins and esterases in larval insect diapause. Twelve-month appointment available immediately (12,500). Send resume, names of three references to:

Dr G. M. Chippendale,
Entomology Department,
1-87 Agric. Bldg.,
University of Missouri,
Columbia, MO 65211, USA.

Equal Opportunity / Affirmative Action Employer. 8704(A)

BERKELEY PHYSICS

The Physics Department of the University of California, Berkeley, expects during the next two years to be making one or two appointments at the assistant professor level. Preferred areas of research are astrophysics, atomic and plasma physics, condensed matter physics, nuclear physics, and particle physics, with some priority given to theoretical particle physics.

Applicants should write before February 1, 1979, to the Chairman of the Physics Department, University of California, Berkeley, CA 94720, U.S.A. giving curriculum vitae, publication list, and references. The University of California is an Affirmative Action Employer. 8679(A)

UNIVERSITY OF NEWCASTLE UPON TYNE
DEPARTMENT OF AGRICULTURAL ENGINEERING
RESEARCH ASSOCIATE

Applications are invited for this post, funded by the Tropical Products Institute for a period of two years.

The work is connected with modelling heat and moisture movements in grain stored in unprotected metal silos subjected to diurnal heating, and experimental verification of the model. Overseas travel may be required.

Candidates should have a Ph.D. (or equivalent experience) in Physics, Chemical Engineering or a subject related to heat and mass transfer and with some computing experience. A knowledge of grain storage practice would be an advantage.

Starting salary within the range £3,883 to £4,382 per annum (under review). Duties to commence as soon as possible.

Applications together with curriculum vitae (three copies), quoting ref. Agric. 157 should be sent to the Registrar, University of Newcastle upon Tyne NE1 7RU, from whom further details may be obtained.

8691(A)

UNIVERSITY OF EXETER

Applications are invited for the post of Instrument Technician Grade 6 in the Department of Biological Sciences, to provide a comprehensive service of maintenance, repair and calibration of a wide range of scientific instruments. The work involves consultation with and advice to academic staff and postgraduates and instructing instrument users. A chemistry background would be an advantage.

Applicants should have an H.N.C. qualification and appropriate experience in the work. Further details can be obtained from the Laboratory Superintendent, Hatherly Laboratories, Prince of Wales Road, Exeter EX4 4PS.

Letters of application including the names and addresses of two referees should be sent to Miss Doreen B. Watson, University of Exeter by December 22, 1978. Please uote reference No. 5104. 8689(A)

TECHNICIAN/ RESEARCH OFFICER

required, from January 1979, to work on immunodiagnosis of leukaemia. Experience in fluorescence techniques, immunology or haematology an advantage.

Salary depending on qualifications within range £3,000 to £4,900.

For application form and job description please write or telephone Mrs Nelson, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2 on 01-242 0200, extn 305. 8768(A)

QUEEN ELIZABETH COLLEGE
Kensington
(University of London)
LECTURESHIP IN THE QUANTITATIVE ASPECTS OF MANAGEMENT

Applications are invited for the post of Lecturer in Management Studies to join a developing group within the Department of Food Science. Applicants will be expected to have an appropriate academic background with an original discipline in areas such as statistics, management science, mathematical economics, econometrics, operational research or economic geography. The successful applicant will be required to teach the application of quantitative methods to management problems to students following interdisciplinary degrees in the natural sciences and management studies. Outside contacts will be encouraged. Industrial or other relevant experience would be an advantage, and placing on the salary scale will reflect both qualifications and experience; the current scale (under review) is £2,909 to £7,754 per annum plus £450 per annum London allowance.

Application forms and further particulars are available from the College Secretary, Queen Elizabeth College, Campden Hill Road, London W8 7AH. Tel.: 01-937 5411, ext. 209. Closing date January 2, 1979. 8746(A)

UNIVERSITY OF WAIKATO
New Zealand
LECTURER OR SENIOR LECTURER IN EARTH SCIENCES

The University has a vacancy for a Lecturer or Senior Lecturer in the Department of Earth Sciences, available from February 1, 1979.

The University wishes to appoint a person with postgraduate qualifications involving at least one of the following: soil classification, soil survey, land use, soil genesis, soil chemistry, or soil physics. Experience in university teaching would be desirable but is not essential; however, the appointee would be expected to be interested in field research and to supervise postgraduate students in such research.

The current salary range for Lecturers is NZ$11,894 to NZ$14,488; and Senior Lecturers NZ$14,983 to NZ$17,145 to NZ$18,380 per annum.

Conditions of appointment and method of application are available from The Registrar, University of Waikato, Private Bag, Hamilton, New Zealand, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on December 20, 1978, but will be accepted for a further 14 days. 8747(A)

FULL PROFESSORSHIP OF BIOCHEMISTRY

available at the **University of Geneva Medical School, Geneva, Switzerland.**

Beside demonstrated abilities to lead an active research, the successful candidate should be able to teach in French.

Send complete resume to: Dr A. F. Muller, President of the Search Committee, Department of Internal Medicine, Hospital Cantonal, 1211 Geneva 4, Switzerland.

8724(A)

CENTRAL PUBLIC HEALTH LABORATORY

NATIONAL COLLECTION OF TYPE CULTURES

SYSTEMS DESIGNER/ PROGRAMMER

A science graduate is required for the computer operation of a bacterial identification service. Bacteria from clinical sources are identified by probalistic analysis of test results by reference to computer-stored data bases. Systems use Optical Mark Reader forms, Data Recognition (Dataterm 3) Machine punch tape terminal connected to the LUCS CDS time sharing system; current software in FORTRAN IV. There is considerable scope for improving the responsiveness of the system and the efficient storage and retrieval of data, and to revise the methodology or explore alternative methods.

Candidates with five years postgraduate experience may be appointed to the Senior Scientist Grade.

Salary on probationary scale £2,991 to £4,275 per annum, plus London Weighting, Post Probationary scale £3,798 to £4,899 per annum, plus London Weighting or Senior Scientific scale, if applicable, £5,451 to £6,837 per annum, plus London Weighting.

Applications to: Personnel Officer, Central Public Health Laboratory, Colidale Avenue, London, N.W.9. Tel: 01-205 7041 for a more detailed job description (Dr L. R. Hill on Ext: 47).

8676(A)

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF ANATOMY AND EMBRYOLOGY

RESEARCH ASSISTANT

(Salary Range IB)

quired for an M.R.C.-supported pro- ct involving electrophysiological udies of neuro-transmitter action on nooth muscle. The successful ap- icant will be supervised by Dr R. D. rves and encouraged to register for Higher Degree. Prior experience in urophysiology or an interest in ysics and electronics is desirable. ppointment for one year in the first stance, with the possibility of an tension to three.

Applications, including curriculum ae and names of two referees, to ofessor G. Burnstock, (N) Dept. of atomy and Embryology, University llege London, Gower Street, London CIE 6BT. 8695(A)

CSIRO

AUSTRALIA

Postdoctoral Research Fellow

Division of Soils

Narrabri, NSW/Canberra, A.C.T.

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: Pedology

General: The Division with headquarters in Adelaide has, through its Canberra Laboratories, a major interest in soil research in the fluviatile landscapes of the main river systems of NSW both in their middle and upper reaches (the water sources areas) and in the alluvial plains where irrigation and intensive agriculture are practised. The predominantly clay soils of the alluvial plains have varying cropping reputations. Some, as in the Namoi Valley in which cotton is grown, are thought to pose management problems associated with structural instability which leads to water logging and aeration deficiencies. A prerequisite for tackling such problems is a though understanding of the nature and properties of the soils and their distribution in the landscape. This provides a basis for examining changes wrought by current practices and for proposing the appropriate management modifications. It can also ensure that field trials are located on representative sites, and enables the confident extension of results of such trials.

Duties: To study the soils, their properties and distribution in relation to landscape in the Lower Namoi Valley and to report on the nature of the interaction between soil features and current systems of management. Attention will be directed to placing these soils in the context of other irrigated clay soils of Eastern Australia.

Qualifications: A Ph.D degree in an appropriate field or postgraduate research experience of equivalent standard supported by satisfactory evidence of research ability.

Note: The Division of Plant Industry in collaboration with the NSW Department of Agriculture has a field research station at Myall Vale, near Narrabri and will provide back-up facilities for the field studies.

Location: Initially the appointee will be stationed at Narrabri where a house is available for rental. Subsequently the appointee will be located in Canberra.

Salary: Research Scientists or Senior Research Scientists: A$14,829—A$21,543 p.a.

Tenure: A fixed term appointment of 5 years.

Applications **IN DUPLICATE,** stating **FULL** personal and professional details, the names and addresses of at least two professional referees, and **QUOTING REFERENCE NUMBER 270/480** should reach:—

The Personnel Officer,
Australian Scientific Liaison Office,
Canberra House,
Maltravers Street,
LONDON,
WC2R 3EH.

by 6th January, 1979.

Applications in U.S.A. and Canada should be sent to:—

The Counsellor (Scientific),
Embassy of Australia,
1601 Massachusetts Avenue, N.W.,
WASHINGTON, D.C., 20036,
U.S.A.

8742(A)

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

(Universtiy of London)

Keppel Street WC1E 7HT

PREVENTIVE TERATOLOGY UNIT

Applications are invited for a

MEDICAL LABORATORY SCIENTIFIC OFFICER IN BIOCHEMICAL TERATOLOGY

to work on congenital malformations associated with environmental agents.

The appointment is for up to 18 months at a salary, depending on age, experience and qualifications, on a scale which rises to £3,930 plus £354 London Weighting.

Applications, stating qualifications and experience and the names of two referees, should be sent to the Secretary (A1) at the School. 8745(A)

M.R.C. CLINICAL RESEARCH CENTRE

(Northwick Park Hospital)

WATFORD ROAD, HARROW

MIDDX. HA1 3UJ

The division of immunological medicine (Head: Dr G. L. Asherson) has a vacancy for imaginative SCIENTIST with biochemical or biological interests to study T suppressor cells and their assay in animals and man.

Salary within the range £3,909 to £7,754 plus L.A. This will be a short term appointment for 3 years.

Candidates may visit the department by telephoning G. L. Asherson 01-864 5311 extn 2691 or further details and application form obtainable from Mrs J. Tucker-Bull, quoting reference 118/1/4194.

Closing date: January 3, 1979.

8767(A)

EUROPEAN MOLECULAR BIOLOGY LABORATORY

IMAGE PROCESSING

Applications are invited for a post in the Instrumentation Division to develop and maintain a user-oriented suite of image-processing programmes, particularly for the analysis of electron micrographs of biological specimens. Extensive experience in the writing, documentation and maintenance of programmes for large image processing problems is necessary. A background in the development of efficient mathematical algorithms for image analysis and a familiarity with applications of electron microscopy in biology is desirable. Experience with small and medium computer configurations, their operating systems and I/O software/hardware writer/user will be useful.

The successful applicant will implement the programmes on a NORD 10/NORD 50, interfaced with an HB5 STEM and driving an FPS array processor and extensive interactive display and I/O systems. There will be remote access to a DEC 1090. Research activities will include the development of new mathematical algorithms to analyse two- and three-dimensional data.

The salary offered will be between DM 3400 and DM 4300 depending on age, qualifications and experience.

Applications, with a curriculum vitae and the names of referees, and quoting reference 78/40, should be sent to:

Sir John Kendrew
Director General
Postfach 10.2209
6900 Heidelberg
Germany

8710(A)

UNIVERSITY COLLEGE DUBLIN

Applications are invited by the Governing Body of the College for the following full-time statutory post:

PROFESSORSHIP OF ORGANIC CHEMISTRY

Prior to application, further information (including details of application procedure) should be obtained from the Secretary and Bursar, University College, Belfield, Dublin 4. Telephone enquiries: 693244, Ext. 431.

The latest date for receipt of completed applications is **Thursday, February 8, 1979.** 8666(A)

We are a major pharmaceutical company with our own large research division.

We require a qualified

neuropharmacologist

as head of our new neuropharmacological laboratory.

Applicants should send a detailed curriculum vitae to

Peter Assent
c/o Grünenthal GmbH
Postbox 1 29
5190 Stolberg Rhld.
Germany

8723(A)

UNIVERSITY OF EDINBURGH

DEPARTMENT OF MOLECULAR BIOLOGY

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the post of Postdoctoral Research Fellow to work on a project funded by the S.R.C. The project is concerned with the separate isolation of copy DNA sequences from *Xenopus* oocyte messenger RNA by molecular cloning and applicants should have experience of nucleic acid research and/or molecular cloning techniques.

The salary is on Range IA (£3,883 to £6,555 per annum) and the post is for three years.

Applications, including a curriculum vitae and the names and addresses of two referees, should be sent to Dr P. J. Ford, Department of Molecular Biology, King's Buildings, Mayfield Road, Edinburgh EH9 3JR. Please quote Reference 5035. 8610(A)

MEMORIAL UNIVERSITY OF NEWFOUNDLAND

DEPARTMENT OF BIOLOGY

FISHERIES BIOLOGY

Applications are invited for a position open at senior rank, in the area of Fisheries Biology. Candidates must demonstrate a strong record of research and publication in fisheries, and a successful background in supervision of fisheries research at the M.Sc. and Ph.D. levels. The successful candidate will play a key role in development of a new fisheries program.

ASSISTANT PROFESSOR—AQUATIC ZOOLOGY

Applications are invited for a position open at the rank of Assistant Professor, in the area of Aquatic Zoology. Enquiries are especially welcome from candidates with specialisation in any of the following areas: marine and freshwater fishes; limnology; planktology; fish population dynamics.

Applicants should submit a *curriculum vitae* together with the names of three referees. Applications close on **January 31, 1979** with Dr G. R. South, Head, Department of Biology, Memorial University of Newfoundland, St John's, Newfoundland A1B 3X9, Canada. 8719(A)

UNIVERSITY OF NAIROBI KENYA

Applications are invited for the post of PROFESSOR in the DEPARTMENT OF ANIMAL PRODUCTION. Candidates should hold a Ph.D. and have considerable experience in teaching at University level, in either Animal Breeding, Animal Management or Animal Nutrition and Feeding. The appointee will be expected to teach both undergraduate and postgraduate students and advise the department on the syllabus currently in force. The minimum period for the appointment is one year.

Salary Scale: Professor K£4,632 to K£5,562 p.a. (K£1=£1.37 sterling). The British Government may provide salary supplementation of £5,796 p.a. (sterling) for married appointee or £4,182 p.a. (sterling) for single appointee (reviewed annually and normally free of all tax) and provide childrens education allowances and holiday visit passages. Family passages: S.S.S.F. or F.S.S.U.; non-contributory medical scheme; subsidised housing/housing allowance.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Registrar (Recruitment and Training), University of Nairobi, P.O. Box 30197, Nairobi, Kenya by January 3, 1979. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

8720(A)

THAI NATIONALS

Faculty positions available for graduates in biochemistry or related fields. Good opportunity to join a young dynamic department with active programs in research (currently: nutrition, reproduction and tropical diseases) and teaching (medical and postgraduate students). Special consideration to those trained in biotechnology, cancer and endocrinology. Send curriculum vitae to **Chairman, Department of Biochemistry, Faculty of Science, Mahidol University, Rama VI Rd., Bangkok, Thailand.**

8717(A)

THE ROYAL HORTICULTURAL SOCIETY

Appointment of Botanist

Applications are invited for the post of Botanist at the Society's Garden at Wisley.

The duties will include advisory work on plant identification, and physiology, genetics and chemistry related to horticulture; demonstrations to trainees, cataloguing and labelling plants at Wisley and Committee work. Graduates in botany or horticulture are preferred.

The salary, reviewed annually, will be related to qualifications and experience. The post is pensionable.

Applications with details of qualifications and experience and the names of two persons to whom reference may be made should be sent so as to reach the Secretary, Royal Horticultural Society, Vincent Square, London SW1P 2PE, by Monday January 15, 1979.

8716(A)

BONN UNIVERSITY and MAX-PLANCK-INSTITUTE FOR RADIOASTRONOMY

Three postdoctoral research positions are open at the

SONDERFORSCHUNGSBEREICH RADIOASTRONOMIE

in theoretical astrophysics (interstellar medium, galactic evolution, pulsars) for one year, possibly three years. SALARY: 40,000 to 48,000 DM per annum. Applications including curriculum vitae, bibliography and the names of two referees should be sent to:

Dr W. Priester, Sonderforschungsbereich Radioastronomie, Auf dem Huegel 71, D 5300 BONN 1, Federal Republic of Germany. 8715(A)

PLANT BREEDING INSTITUTE

Maris Lane, Trumpington
Cambridge CB2 2LQ

HIGHER SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER

CYTOGENETICS DEPARTMENT

A Molecular Biologist is require to participate in and be responsibl for parts of a programme of studyin plant chromosomes, isolating plan genes and producing vectors an specific nucleotide sequences for th transformation of plant cells.

Candidates should have a 1st o Upper 2nd Class Honours Degree i an appropriate biological science an at least two years' postgraduate experience in molecular biology o related fields of biochemistry.

The appointment will be as Highe Scientific Officer (£4,101 to £5,448 pe annum) or Senior Scientific Office (£5,154 to £6,898 per annum). At leas four years' postgraduate experience i required for appointment as Senio Scientific Officer.

Applications with curriculum vita and the names and addresses of thre referees should be sent to the Assista Secretary (Establishment) by Decembe 22, 1978.

Please quote reference CYT/35.

8712(A)

UNIVERSITY OF IFE NIGERIA

Applications are invited for the following posts in the Faculty of Pharmacy:—

1. PROFESSOR IN DEPARTMENT OF PHARMACOGNOSY (incorporating DRUG RESEARCH UNIT).
2. PROFESSOR IN DEPARTMENT OF PHARMACEUTICALS. Candidates should have considerable teaching and research experience in the field of Pharmaceutical Technology or General Pharmaceutics.

Salary Scale: Professor, N11,268 to N12,420 p.a. (£8,942 to £9,857 p.a. sterling). (£1 sterling=N1.26.) There may be supplementation by £2,160 p.a. (sterling) for married appointees or £Nil p.a. (sterling) for single appointees and provision of children's education allowances and holiday visit passages. Fringe benefits include pension scheme or contract addition of 25% of salary (partly taxable); family passages; baggage allowances; car and housing allowances; various allowances.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent to Registrar, University of Ife, Ile-Ife, Nigeria, by January 4, 1979.

Applicants resident in the U.K. should also send one copy to the Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 8774(A)

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a post of DEMONSTRATOR from candidates who have, or have submitted for, a Ph.D. in Biochemistry, for a period up to three years, tenable as soon as possible. The duties will involve participation in departmental teaching and in one of the research projects currently in progress. These include membrane transport of nucleic acid precusors, the role of folding units in enzyme structure, DNA repair and genetic recombination in E. coli, genetic engineering, triglyceride and lipoprotein metabolism, enzymology of resistance in antibiotics, lactose transport and bioenergetics in E. coli.

Salary will be at an appropriate point on the Grade 1B (Bar) scale: £3,384 to £4,882 per annum, according to age, qualifications and experience. Membership of the appropriate University superannuation scheme will be required.

Further particulars may be obtained from the Registrar, The University, Newcastle upon Tyne NE1 7RU with whom applications (two copies), together with the names and addresses of three referees should be lodged not later than December 21, 1978. Please quote reference N. 8685(A)

THE ROYAL SOCIETY

The Royal Society requires a science graduate (up to 25-years-old) to assist in its editorial department. General aptitude for scientific editorial work required; sound grounding in mathematics and knowledge of biological nomenclature necessary. Progressive salary scale and superannuation scheme. Commencing salary up to £4,395 per annum depending on age and experience. Applications with names of two referees to the Executive Secretary, 6 Carlton House Terrace, London SW1Y 5AG by January 2, 1979, marking the envelope 'Personal W.G.E.'. 8729(A)

TECHNICIAN (Grade 5) required in Department of Microbiology, University of Reading. Main duties include supervision of laboratory services in section dealing with teaching and research in Microbial Physiology and Biochemistry; equipment for teaching and research; chemical stores. Salary according to qualifications and experience in range £3,186 to £3,720 p.a. (under review). Further details available on request. Apply, stating qualifications and experience and giving the names of two referees, quoting Ref. T.N. 74A, to Assistant Bursar (Personnel), University of Reading, Whiteknights, Reading RG6 2AH. 8751(A)

HOUGHTON POULTRY RESEARCH STATION

GENETICIST

A vacancy exists in the Leukosis Experimental Unit for a geneticist to study the inheritance and nature of resistance of chickens to oncogenic and other viruses, and to assist in the formulation of breeding programmes for the Institute's flocks.

Applicants must have a first or upper second class honours degree, with genetics as a major subject in the first or a higher degree, and preferably a Ph.D. or at least 3 years' relevant postgraduate experience. A minimum of four years' relevant postgraduate experience is required for the S.S.O. grade.

The appointment will be to the Higher Scientific Officer grade (£4,101 by 8 to £5,448) or the Senior Scientific Officer grade (£5,154 by 8 to £6,898), grade and starting salary depending upon experience. Non-contributory superannuation scheme.

Further particulars and application forms from the Station Secretary, Houghton Poultry Research Station, Houghton, Huntingdon, Cambs. PE17 2DA. Closing date for applications is January 10, 1979.

MASSEY UNIVERSITY

Palmerston North, New Zealand

LECTURESHIP IN BOTANY

The Department of Botany and Zoology has a vacancy for a botanist with a general interest in the teaching of biology and research interests in developmental plant physiology and/or morphology. However, all applicants with interests in experimental plant science will be considered.

The successful candidate who will preferably have a Ph.D. may be expected to contribute to courses in plant morphology, morphogenesis, developmental plant physiology, developmental biology and cytology. The Botany and Zoology Department is well-equipped for experimental and field research. The Department is involved in teaching at all levels within the University, and has increasing commitments to extra-mural courses serving the whole of New Zealand.

Salary NZ$11,894 to $14,488.

Further details of this position, and of this University, and Conditions of Appointment, may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or the Registrar of the University.

Applications close on **January 19, 1979.** 8718(A)

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF BIOCHEMISTRY

RESEARCH TECHNICIAN

(Grade 3)

required for Monoclonal Antibody Production and Biochemical Investigations of Erythrocyte Proteins, particularly those affected by Heredity Spherocytosis, to work in a new well-equipped reserch group investigating cell membrane diseases. A sound biochemical background and previous experience in tissue culture, protein chemistry, electrophoresis and/or chromatography are disirable.

The appointment is from January 1, 1979 initially until July 31, but extendable subject to continuing support from granting agencies, at a starting salary of £3,153 (under review) including London Weighting.

Write or telephone soon for an application form to the Departmental Superintendent, Biochemistry Department, Imperial College, London SW7 2AZ. Tel: 01-589 5111 Ext. 1119, quoting reference DMS RT3.

8713(A)

WILTSHIRE Area Health Authority

Salisbury Health District

Scientific Officer

(Basic Grade)

required to work in the Burns Research Unit at Odstock Hospital, Near Salisbury. This post is suitable for a graduate in Science (or equivalent qualifications) with an interest in studying the structure, metabolism and response to injury of human tissues and organ systems. The appointee will undertake laboratory work under the supervision of the Principal Scientific Officer (Dr P. G. Shakespeare), but there will be opportunity to develop their own ideas within the sphere of interest of the laboratory.

Application Forms and Job Descriptions available from District Personnel Department, Odstock Hospital, Salisbury, Wilts. Closing date 31st December, 1979. 8694 (A)

Western Australian
Institute of Technology

RESEARCH ASSOCIATE – ISOTOPE GEOCHRONOLOGY

DEPARTMENT OF PHYSICS

Applicants will be required to work on the establishment of the Sm-Nd geochronological method and its application to a range of problems in the development of the Archaean crust of W.A. The department has continuing Rb-Sr program in association with the Geological Surveys of W.A., and proposes to supplement this with Sm-Nd work as an integral part of this joint geochronological research.

Applicants require a recently completed higher degree in isotope geochronology or closely aligned discipline, and must have shown independent analytical ability.

Applicants required to commence work in Perth early in 1979.

APPOINTMENT: at an annual salary $13,200, with limited relocation expenses will be for two years. Appointment at a higher level may be possible for applicants with substantial direct experience of Sm-Nd techniques.

APPLICATIONS: with full personal details and the names and addresses of two referees, should be submitted by 22nd December, 1978 to K. Rosman, Department of Physics, Western Australian Institute of Technology, Hayman Road, South Bentley, 6102, Western Australia.

8673(A)

AN FORAS TALUNTAIS

requires

AGRICULTURAL SCIENCE GRADUATES (2)

to participate in the dairy husbandry research programme of the Moorepark Research Centre, Fermoy, Co. Cork. One appointment will be up to and including Principal Research Officer level (salary minimum £9,387), the other up to and including Senior Research Officer level (salary maximum £8,465). Marriage and Children's allowances, Non-contributory Pension Scheme and provision for Widows' and Orphans' pensions.

ESSENTIAL: An Honours University Degree or equivalent in Agricultural Science.

DESIRABLE: Suitable research or other relevant experience.

Application forms and further particulars from Personnel Department (ref. M.O.R.), An Foras Taluntais Headquarters, 19 Sandymount Avenue, Dublin 4 (Phone: 01-688188). Latest date for receipt of completed forms: January 5, 1979. 8699(A)

There is a vacancy for a BIOLOGIST in *Nature's* London office. He or she would join the team which assesses the suitability of biological manuscripts for publication; there would also be opportunities to work with members of the *Nature* staff in compiling other sections of the journal. The job might appeal to the holder either of a bachelor's or an advanced degree.

Write to:

ST JAMES'S HOSPITAL, LEEDS, YORKS

Applications are invited from candidates with an Honours degree in one of the Biological Sciences for the post of SCIENTIFIC OFFICER in the Regional Cytogenetic Unit established at this hospital. The Unit undertakes the cytogenetic investigations required for patients within the area covered by the Leeds Regional Health Authority.

Salary: Starting at £3,486 rising annually to £4,275.

Applications, giving the names and addresses of two referees should be submitted to:

Central Personnel Office
St James's University Hospital
Beckett Street
Leeds LS9 7TF

Closing date for receipt of applications: December 28, 1978. 8750(A)

THE DIVISION OF
ENTERIC PATHOGENS
has a vacancy for a

MEDICAL LABORATORY SCIENTIFIC OFFICER

Suitable qualifications would be a relevant Science degree, A.I.L.M.S. or H.N.C. with experience in Microbiology.

The successful applicant will work in the Drug Resistance Research Unit, which is concerned with studies on the epidemiology and ecology of transferable drug resistance in the enterobacteria.

Applications to: Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT. Tel: 01-205 7041. 8744(A)

UNIVERSITY OF OXFORD

University Lectureship in Atmospheric Physics

Applications are invited from persons with a background in atmospheric physics, dynamical meteorology or geophysical fluid dynamics for the above post in the Department of Atmospheric Physics. The successful candidate may be offered a tutorial fellowship by Merton College. Details of the University and College appointments may be obtained from Professor J. T. Houghton, F.R.S., Department of Atmospheric Physics, Clarendon Laboratory, Oxford University, to whom completed applications should be sent by January 31, 1979.

8732(A)

UNIVERSITY OF NAIROBI KENYA

Applications are invited for the following posts in the

DEPARTMENT OF AGRICULTURAL ENGINEERING

PROFESSOR

Applicants should have a Ph.D., or at least an M.Sc., in agricultural engineering plus several years' teaching experience at University level and knowledge of development of farm power and machinery systems for tropical agriculture in developing countries. Research experienre in farm power and machinery would also be an advantage. The appointee is expected to take a leading role in the development of teaching and research in the required specialism. The teaching will be at both undergraduate and postgraduate levels to both agricultural and agricultural engineering students. The appointment will be on contract terms.

PROFESSOR (SOIL AND WATER ENGINEERING)

Applicants should have a Ph.D., or at least an M.Sc., in agricultural engineering, hydrology or a related field. Several years' teaching experience at university level in the development methods for soil and water conservation in developing countries is essential. Research experience in soil conservation engineering or soil and water management, would be an advantage. The appointee is expected to take a leading role in the development of teaching and research in the indicated fields. The teaching will be at undergraduate and postgraduate level to both agricultural and agricultural engineering students. The appointment will be on contract terms.

Salary scale: K£4,632 to K£5,562 per annum (K£1 equals £1.37 sterling). The British Government may provide salary supplementation of £5,796 per annum (sterling) for married appointee or £4,182 per annum (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages; S.S.S.F. or F.S.S.U.; non-contributory medical scheme; subsidised housing/housing allowance. Detailed applications (two copies) with curriculum vitae and naming three referees to be sent to Registrar (Recruitment and Training), University of Nairobi, P.O. Box 30197, Nairobi, Kenya by January 3, 1979. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 8708(A)

PLANT BREEDING INSTITUTE

Maris Lane, Trumpington
Cambridge CB2 2LQ

HIGHER SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER

CYTOGENETICS DEPARTMENT

A Cell Biologist is required for a period of three years to carry out a feasibility study of transferring DNA into cereals and related species using techniques involving cell or tissues other than cell protoplasts where whole plant regeneration may be a problem.

Candidates should have a 1st or Upper 2nd Class Honours Degree in an appropriate biological science and at least two years' postgraduate experience in cell biology or related research including practical experience of micromanipulation techniques.

The appointment will be as Higher Scientific Officer (£4,101 to £5,448 per annum) or Senior Scientific Officer (£5,154 to £6,898 per annum). At least four years' relevant postgraduate experience is required for appointment as Senior Scientific Officer.

Applications with curriculum vitae and the names and addresses of three referees should be sent to the Assistant Secretary (Establishment) by December 22, 1978.

Please quote reference CYT/34.

8733(A)

Avon Area Health Authority (T)

Southmead Health District

SOUTHMEAD HOSPITAL

Bristol

SENIOR BIOCHEMIST

Applications are invited from suitably experienced persons for the above post in the Department of Clinical Chemistry. The Department has a Consultant Chemical Pathologist and a Top Grade Biochemist and serves a large District General Hospital which also carries out clinical teaching for the University of Bristol. The laboratory is well equipped and has a variety of research interests, mainly in the fields of paediatric biochemistry and immunoassays. The person appointed will probably be expected eventually to take day-to-day responsibility for the steroid/infertility section of the laboratory under the direction of the Principal Biochemist. This section performs a range of steroid analyses and provides an Area service for foeto-placental function tests and infertility investigations.

Further information available from: Dr D. J. Goldie (Tel: 0272 505050, Ext: 51) or Dr J. B. Holton (Tel: 0272 505050, Ext. 52).

Application forms obtainable from: The District Personnel Officer, Southmead Hospital, Bristol BS10 5NB. (Tel: 0272 505050, Ext. 162) and should be returned by December 31, 1978.

8725(A)

POSITION AVAILABLE IMMUNOLOGIST/IMMUNOPATHOLOGIST

The Department of Pathology, Hematopathology Section, University of Southern California School of Medicine, is seeking applicants who have recently completed a Ph.D. program in the areas of immunology/immunopathology for full-time appointment as research associate/scholar. Applicants should be qualified in the areas of cellular immunology and tissue culture and should have experience with mice. Salary negotiable. Following appointment qualified individuals will be encouraged to seek faculty status. Please send curriculum vitae, description of present and future research and names of references to: Dr Paul K Pattengale, U.S.C. School of Medicine, 2025 Zonal Avenue, Los Angeles, CA 90033.

Affirmative Action/Equal Opportunity Employer. 8703(A)

GLASSHOUSE CROPS RESEARCH INSTITUTE

requires SCIENTIFIC OFFICER/HIGHER SCIENTIFIC OFFICER in **PLANT BREEDING DEPARTMENT** for work on genetic control of lateral shoot initiation and development in tomato. Applicants should have First or Upper Second class Honours degree in a biological subject, with specialisation in genetics supported by biochemistry and plant physiology. Salary within scale £2,839 to £4,415 (S.O.) or £4,101 to £5,448 (H.S.O.) according to qualifications and experience. At least two years relevant postgraduate experience required for appointment as H.S.O. Non-contributory superannuation scheme. Further details available. Applications giving full biographical details and names and addresses of two referees to Secretary, Glasshouse Crops Research Institute, Worthing Road, Rustington, Littlehampton, West Sussex BN16 3PU by January 2, 1979.

8741(A)

BEATSON INSTITUTE FOR CANCER RESEARCH

SCIENTIST

A vacancy exists for a scientist to join a team studying the role of RNA tumour viruses in differentiation and transformation. The appointment is on a new five-year M.R.C. programme. Applicants should have experience in the general area of Cell Biology/Molecular Biology. Salary will be on the University of Glasgow scales for Research Staff and will be negotiable according to experience. For further information contact Prof. W. Ostertag or Dr I. B. Pragnell, Beatson Institute for Cancer Research, Wolfson Laboratory for Molecular Pathology, Garscube Estate, Switchback Road, Bearsden, Glasgow G61 1BD.

TEXT BOOK EDITOR

Experienced text Book Editor of proven accomplishments to originate and develop lists in several disciplines, not exclusively scientific, at higher undergraduate level He or she will require an appreciation of the requirement of academics, students and markets within and without the United Kingdom He or she will report to the editorial director, and liaise with a small team of procurement editors, but will also enjoy considerable autonomy

Salary will be in excess of £6,000 and the company has a generous non-contributory pension scheme

Please write giving curriculum vitae to

Anthony Watkinson,
Senior Editor,
Academic Press Inc (London) Ltd ,
24–28 Oval Road,
London NW1 7DX.

UNIVERSITY OF RHODESIA
SCHOOL OF AGRICULTURE
TECHNICIAN AGRICULTURAL ENGINEERING

Applications are invited for the post of Technician in the newly-established Department of Land Management, in the School of Agriculture at the University of Rhodesia.

Duties. The successful applicant will assist with the practical classes, research and development work in Agricultural Engineering and Farm Mechanisation. He will be responsible for running a workshop and will be required to do outdoor work with field machinery The Workshop is equipped with a lathe, gas-electric webbing equipment and woodwork machinery

Further particulars with regard to these duties may be obtained by writing to the Chief Technician, School of Agriculture, University of Rhodesia, PO Box MP 167, Mount Pleasant, Salisbury, Rhodesia

Qualifications: Applicants should have served an apprenticeship or had similar training in workshop practice including the care of machine tools,) N C. City and Guilds full technological certificate or similar qualification would be an advantage, as would previous experience in similar work, particularly in Africa.

Salary Scale (Approx Stg. equiv): echnician/Senior Technician. £3,880 y 207 to £4,915 (Scale Barrier) by 79 to £6,868 per annum Entry point according to qualifications and experience up to a maximum commencing salary of £4,915 per annum

Applications: Six copies giving full details of personal particulars, qualifications, experience and the names of three referees should be sent to the Assistant Registrar (Science), University of Rhodesia, PO Box MP 167, Mount Pleasant, Salisbury, Rhodesia.

Closing date for receipt of applications. **December 31, 1978.**

British subjects considering applying for posts in Rhodesia are urged to consult the Foreign and Commonwealth Office (telephone 01-233 8777) their nearest British Consular Office.

8734(A)

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF GEOLOGICAL SCIENCES
RESEARCH ASSOCIATE IN CRUSTAL SEISMOLOGY

The Associate will be concerned with running a network of temporary recording stations in the German Rheinish Massif for the period April-June, 1979 and analysing the data obtained, using the information from a concurrent explosion experiment to give a good control on crustal structure Applicants should have a good honours degree in geophysics, geology or physics with preferably some experience of seismological recording equipment. The appointment is tenable until June 30, 1981. Salary will be in the range £3,384 to £4,882 (under review), plus superannuation Starting salary will not exceed £3,883.

Further particulars are available from the Assistant Registrar, Science and Engineering, University of Birmingham, P O Box 363, Birmingham B15 2TT, to whom applications (three copies) including full curriculum vitae and naming three referees should be sent by Monday, January 1, 1979

LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY
SPRING 1979 AWARDS
Next deadline: February 20, 1979

The long term fellowships will usually be for a period of up to one year but applications for a renewal for a second year are considered To be eligible a candidate must hold a doctors degree. Preference will be given to European and Israeli applicants wishing to work within Europe or Israel, EMBO long term fellowships are NOT, however, awarded for exchanges between laboratories within any one country Applications for fellowships to be held outside Europe and Israel are considered but they have a lower priority, as do applications from non-European scientists wishing to work in Europe or Israel

The deadline for applications for the 60 fellowships to be awarded in April 1979 is February 20, 1979 Because the selection procedure involves an interview this deadline should be respected

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organisation, 69 Heidelberg 1, Postfach 1022 40, F R Germany 8682(E)

THE UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF ANATOMY
POSTDOCTORAL RESEARCH FELLOWSHIP

A postdoctoral biochemist is required to join a multidisciplinary team studying aspects of growth and differentiation The successful candidate will be responsible for a new M.R C-funded project involving the use of monoclonal antisera to study protein polymorphism in muscle Technical support will be available. The post is for three years beginning as soon as possible and the salary will be on the Research Fellow 1A scale £3,883 to £6 555 plus superannuation

Applications (three copies), enclosing a curriculum vitae, details of research experience and the names of three referees, should be sent to the Assistan Registrar, Faculty of Medicine, University of Birmingham, Birmingham B15 2TJ, from whom further information may be obtained Closing date January 5, 1979 Please quote reference RF/ANT/478 8753(E)

FELLOWSHIPS (continued)

MASSEY UNIVERSITY

Palmerston North, New Zealand

POSTDOCTORAL FELLOWSHIPS

Applications are invited for Postdoctoral Fellowships tenable in any Department of the University.

The academic activities of the University are grouped under the following faculties and schools.

Opportunities for study and research are available in the following fields.

AGRICULTURAL AND HORTICULTURAL SCIENCE

Agricultural Economics and Marketing
Farm Management
Agricultural Engineering
Agronomy
Animal Science (Dairy, Sheep, Beef, Pigs)
Horticultural Science and Plant Health
Poultry Science
Soil Science

BUSINESS ADMINISTRATION

Agricultural Business
Business Studies
Data Processing
Economics
Financial Management and Accounting
Marketing
Personnel Administration

FOOD SCIENCE AND BIOTECHNOLOGY

Food Technology
Biotechnology (i.e. processing of Biological Materials)
Industrial Management and Engineering
Industrial Management and Industrial Mathematics

HUMANITIES

English
History
French
German
Philosophy

SCIENCE

Biochemistry
Biophysics
Botany
Chemistry
Genetics
Microbiology
Zoology

SOCIAL SCIENCE

Applications from scholars in any of the usual Social Science disciplines will be welcomed, but particular preference may be given to those interested in Educational Sociology, Human Geography and/or Planning, Mathematics, Social and Applied Psychology, and Economics.

VETERINARY SCIENCE

Physiology and Anatomy
Veterinary Pathology and Public Health
Clinical Sciences

Information concerning the research activities of the departments associated with these groups are given in the University Calendar. Intending applicants are advised to write to the Head of the appropriate department in the University in the course of preparing an application.

The Fellowship will be tenable for one year, with possible extensions, and carries an emolument of NZ$8,500. Travelling expenses up to NZ$1,500 may be provided.

Further details of the awards and of the University, together with conditions of appointment and information to be supplied by applicants, may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close on **January 19, 1979.**

8721(E)

Mental Health Foundation

FELLOWSHIPS

Applications are invited for **Mental Health Foundation Fellowships** from suitably qualified persons wishing to pursue **Full-time Research Work** bearing on problems of mental health, mental illness or mental handicap, whether in clinical psychiatry or in one of its supporting sciences.

Both **Junior and Senior Fellowships** are offered in the salary ranges of Junior/Senior Lecturer, Junior/Senior Registrar, according to seniority and experience, plus superannuation. However, Senior Fellowships are only awarded under exceptional circumstances, e.g., as a temporary measure prior to the Fellow taking up a permanent career post. The appointments, which are also open to candidates from overseas, will be for up to **three years** in the first instance and in exceptional circumstances may be extended to **five years**. Interviews will be held in May in London and the Fellowships will be taken up between the following July 1 and March 31. Overseas candidates, if shortlisted, must attend for interview at their own expense.

Closing date: March 1.

Application forms and further information may be obtained from The Secretary (N), The Research Committee, Mental Health Foundation, 8 Wimpole Street, London W1M 8HY.

8669(E)

UNIVERSITY OF DUNDEE

Candidates with appropriate postgraduate qualifications in Biochemistry are invited to apply for appointment to a

POST DOCTORAL RESEARCH FELLOWSHIP

to work with Dr J. L. Young (Department of Obstetrics and Gynaecology) and Dr D. A. Stansfield (Department of Biochemistry) on a M.R.C. funded study of the hormone receptor/adenylate cyclase complex of the corpus luteum.

The appointee will be based in the Department of Obstetrics and Gynaecology at Ninewells Hospital and Medical School, Dundee but close co-operation with the Department of Biochemistry will be maintained.

The appointment is available now for a period up to November 30, 1981. The initial salary will be dependent of qualifications and experience but within the range £3,883 to £5,555

Applications, quoting Reference EST/69/78J and containing the names of two referees, should be lodged as soon as possible with The Secretary, The University, Dundee DD1 4HN.

8697(E)

1979 BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH

Notice is hereby given that an election of Junior Beit Fellows to begin work on October 1, 1979 will take place in May 1979. Junior Fellowships carry an initial value of £3,883 to £4,631 plus £450 London Allowance, plus yearly increments for three years. There will be the usual university superannuation contributions and benefits. Candidates must have taken a degree in a faculty of a university approved by the Trustees in Her Majesty's Dominions, Protectorates and Mandated Territories, India, Pakistan, the Republic of Ireland and the United Kingdom, or a medical diploma registrable in the U.K. Elections to Junior Fellowships are rarely made above the age of 35 years. Applications must be received from candidates not later than March 23, 1979. Candidates must submit evidence where they propose to work; which must be in Great Britain or Ireland.

Forms of application and all information may be obtained from Professor W. G. Spector (Secretary), Pathology Department, St Bartholomew's Hospital, London EC1A 7BE. For overseas candidates forms of application may be obtained from, The Secretary, South African Medical Council, P.O. Box 205, Pretoria, South Africa, The Ministry of Health, The Government of India, New Delhi, India, The Secretary, Department of Education and Science, P.O. Box 826, Canberra City, A.C.T. 2601, Australia; The Department of Health, Wellington, New Zealand; and, The Canadian Medical Association, 1867, Alta Vista Drive, Ottawa 8, Ontario, Canada

8668(E)

UNIVERSITY OF ABERDEEN

DEPARTMENT OF GEOLOGY AND MINERALOGY

POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited from suitably qualified organic geochemists or clay mineralogists to work with Dr M. J. Pearson on the correlation of organic matter and clay mineral diagenesis in sediments from the North Sea Basin. The project involves the study of kerogen maturation and hydrocarbon generation during burial in relation to clay mineral transformations as a response to temperature increase and ion concentration in

The post is tenable for three years and is supported by the Natural En-
Interstitial water.
vironment Research Council.

Salary £3,883 to £4,382 per annum on Research and Analogous Staff Range 1A Scale.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (two copies) should be lodged by December 29, 1978

8730(E)

UNIVERSITY OF LIVERPOOL

RESEARCH FELLOWSHIPS

The University is offering a small number of University Research Fellowships to be held in any Department of the University from October 1, 1979 for periods of up to three years. Salary will be in the range £3,883 to £7,754 p.a. (under review) depending on age and experience. Further particulars and application forms may be obtained from the Registrar, The University, P.O. Box 147, Liverpool L69 3BX, by whom completed forms should be received not later than January 31, 1979. Quote Ref: RV/998/N

COURSES

European Molecular Biology Organisation

EMBO PRACTICAL COURSE INTRACELLULAR Ca^{2+} MONITORING TECHNIQUES

Gif sur Yvette, France

June 11–21, 1979

The course is intended for workers who will find intracellular Ca^{2+} monitoring techniques of immediate use in their research programmes. Participants will be trained in the use of the most advanced techniques for monitoring free Ca^{2+} changes in living cells; i.e. photoproteins, metallochromic indicator dyes, and Ca^{2+} sensitive microelectrodes. Most of their time will be spent in the laboratory, working in groups of three, applying these techniques to nerve and muscle cells. There will also be lectures by the teaching staff, and seminars by invited speakers.

Instruction will be in English. In addition to the course organisers and the staff at Gif sur Yvette (G. Baux, R. T. Kado, T. Shimahara, M. Thieffry) teachers will include A. K. Campbell, M. V. Thomas, R. Rudel and M. Oehme.

The course is for a maximum of 15 participants. Applicants should preferably have some experience of electrophysiological techniques, and give a convincing reason for taking the course. Applicants should also include a brief curriculum vitae and be sent to Dr J. Stinnakre by February 15, 1979.

Acceptance for the course will be notified to applicants by April 1, 1979. Some grants will be available to partially defray living and travel expenses. Accommodation will be arranged by the course organisers.

Course organisers:

J. Stinnakre, Cours EMBO, Laboratoire de Neurobiologie cellulaire de C.N.R.S., F 91190 Gif sur Yvette, France.

I. Parker, Biophysics Department, University College London, London WC1E 6BT, U.K.

COURSES continued

EUROPEAN MOLECULAR BIOLOGY ORGANIZATION

LABORATORY COURSE ON RECOMBINANT DNA

10-27 JULY 1979

INSTITUT DE RECHERCHE EN BIOLOGIE MOLECULAIRE
2 Place Jussieu, Paris, France

The experimental programme will include·

In vitro recombination of DNA segments with plasmid and viral vectors

In vitro packaging of bacteripohage lambda DNA, Cosmids

Cloning in *E. coli, B. subtilis* and *S. cerevisiae*

Characterization of cloned recombinant DNA by restriction mapping, hybridization and sequencing

The teaching staff will include:

M L BACH (Strasbourg)
G. CUNY (Paris)
J DOLY (Paris)
S D. EHRLICH (Paris)
C GAILLARD (Paris)
A. GOZE (Paris)
A. HINNEN (Basel)
B. HOHN (Basel)
A. KLIER (Paris)
M MEUNIER (Paris)
B NIAUDET (Paris)
V SGARAMELLA (Milan)
F STRAUSS (Paris)

Introductory and research seminars will be given by members of the teaching staff and by invited speakers

Attendance at the Course will be limited to 20 participants Preference will be given to applicants from Europe

The registration fee will be 500 FF The participants will normally be expected to pay their own travel, accommodation and living expenses

Applications with a short curriculum vitae and any information which might help in the evaluation of the application should reach by March 31, 1979, Dr Giorgio Bernardi at the above address

S.R.C CASE STUDENTSHIP

Cost and Energy Evaluation of Mineral Extraction Processes

A Science Research Council C A S E Studentship is offered in association with the Department of Industry, Warren Spring Laboratory for a study to develop a methodology of cost and energy evaluation of mineral extraction processes The methodology will be developed with particular reference to the extraction of alumina from indigenous U K resources of aluminiferous materials

Candidates from any background will be considered, but the study would be of particular interest to those with experience in mineral technology, extraction metallurgy, chemical engineering or chemistry

Applicants should have, or expect to obtain a 1st or upper 2nd class honours degree

Applicants should send details of their qualifications plus the names and addresses of two referees, to Professor R N Pryor, Head of Department, Department of Mineral Resources Engineering, Imperial College of Science and Technology, Prince Consort Road, London SW7 2BP. 8773(F)

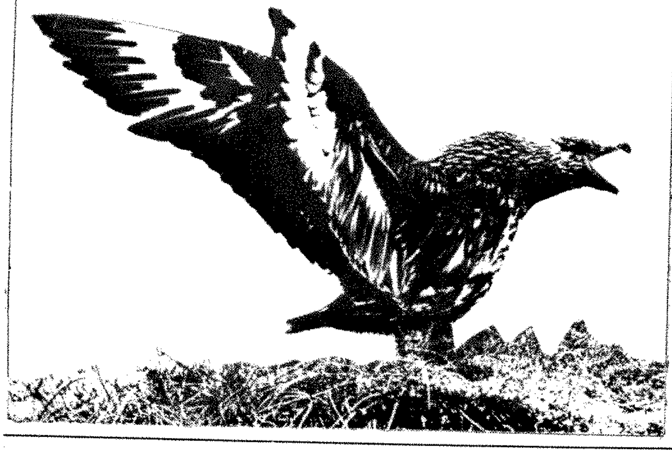
Lively, readable and reliable, British Birds is the monthly journal for all British and Irish birdwatchers, professional and amateur alike. An internationally respected scientific journal, issues of British Birds build into a valuable reference work.

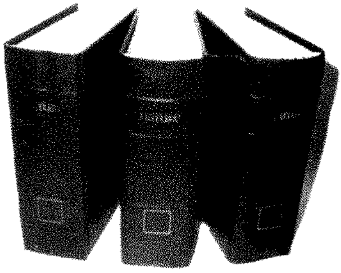
For a year's subscription send your name address, and £12 (overseas US $19.50 in any currency at the current exchange rate) to Macmillan Journals Ltd., Subscription Dept., Brunel Road, Basingstoke, Hampshire RG21 2XS.

A free copy is available from the above address.

British Birds



Nature Binders



Keep your copies of Nature protected in durable black PVC binders:
* 20 plastic retention strips mean no loose parts, wire, or complex loading systems
* title blocked in gold on spine
* panel on spine for your own references
Each binder is designed to take two volumes of Nature; three binders will serve for a year.

Prices (including postage): UK £3.00 each, three for £8.00
Rest of World US $6.00, three for US $16.00

Orders with correct remittance should be sent to:
Nature, Circulation Department, Macmillan Journals Ltd,
Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

nature

Back indexes

- 1971 through 1977 still available
- assist quick, easy reference to the year's papers, listing by both author and subject
- easily accommodated in Nature binders

Prices

UK £5.00 each
Rest of World US$10.00 each

(Payment may be made in any currency at the prevailing exchange rates. Cheques should be made payable to Nature. *All prices include postage.)*

The Second Translation Kit

From the people who brought you new convenience and reproducibility with the first.

The First Translation Kit
It will make your life easier and your results more reproducible

New England Nuclear offers the first reticulocyte lysate kit for use in studying protein synthesis. Not only does it save all of the trouble of preparing your own cell extract, it gives you a system free from endogenous mRNA, high in protein synthesis activity, with an optimized high-activity tracer and quality control that includes testing every lot of Methionine, L-[^{35}S] using the kit.

The rabbit reticulocyte lysate system is reported to contain all factors required for translation of any eukaryotic mRNA! But its use assumes the availability of suitable animals, preparation of the lysate extract, and inactivation of endogenous mRNA. And the meticulous tailoring of the salts, energizer, and amino acid mix. In short, it's a nuisance.

With our exclusive kit you bypass all that and concentrate on the study of protein synthesis. The kit contains:

A rabbit reticulocyte lysate — Treated with nuclease to inactivate endogenous mRNA, and tested to guarantee high protein synthesis activity.

The finest tracer available — NEG-009T, NEN's translation grade [^{35}S] Methionine, >600Ci/mmol, tested for incorporation into protein in cell-free translation systems. Each lot is optimized for compatibility with the system.

Translation cocktail — All the necessary components for proper translation conditions, 19 amino acids (excepting methionine) plus buffer, reducing agent, and energizer.

Control mRNA — Purified exogenous mRNA (adenovirus-infected HeLa cell mRNA) to check the biological activity of the system.

Salts and sterile deionized water — Selected and prepared to minimize potential ionic or enzymatic inhibition of the system.

And you can get rid of all those rabbits

The protocol is straightforward, and it includes suggested final assay procedures. So that's our message. Now add yours.

Call us toll free for details

New England Nuclear

First, Methionine...

Our first translation kit saved you the difficulty of preparing your own lysate for cell-free translation studies, gave you a system free of endogenous mRNA and high in protein synthesis activity, and assured you of components tested for compatibility and reproducible results. All told, it was an excellent excuse to stop cultivating rabbits.

Our second kit does all of the above, too. But, instead of Methionine, L-[^{35}S], the tracer is Leucine, L-[3,4,5-^{3}H]—specially optimized for use with this system. Here's what our Leucine Translation Kit contains:

Rabbit reticulocyte lysate Treated with micrococcal nuclease to inactivate endogenous mRNA and tested to guarantee high protein synthesis activity.

High activity ^{3}H tracer NET-460T, Leucine, L-[3,4,5-^{3}H], >110Ci/mmol. Special lots are prepared and tested for incorporation into protein using this cell-free translation system.

Translation cocktail All the necessary components for proper translation conditions, including buffer, biogenic polyamine, and energizer.

Control mRNA Purified mRNA to check the biological activity of the system.

Salts and sterile deionized water Selected and prepared to minimize potential ionic or enzymatic inhibition of the system.

Instructions for use The protocol is straightforward and includes suggested assay procedures.

So now there are two, and only two, translation kits. Call us toll-free for details on either or both.

Caution: Not for use in humans or clinical diagnosis.

Sephacryl®

the different medium for gel filtration

- **Faster separations: Sephacryl has speed and resolution to spare; separates proteins 5–10 times faster than conventional media.**
- **Faster packing: Sephacryl is pre-swollen, ready-to-use and packs fast.**

Use Sephacryl S-300 Superfine for separations up to an exclusion limit of 1.5 million for globular proteins; ideal for serum proteins. Use Sephacryl S-200 Superfine up to an exclusion limit of 250,000 for globular proteins.

When you use Sephacryl, the difference is clear. Find out more about Sephacryl from your usual supplier of Sephadex®, Sepharose® and other separation media.

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258,**1 (1975) and **264,** v, 11 Nov. (1976).

ot just an instrument... a totally new u Pont LC system.

Du Pont's new high-performance Model 850 gives you full visual display, instant adjustment, all the versatility, reliability and speed you want.

This new Du Pont LC system ives the operator immediate call-cut nowledge of all key operating paraeters and the ability to change those arameters while the system is unning.

Other features of the Du Pont 50 include

- a precision constant-volume 3-piston pump
- microprocessor control of components
- immediate operator access while system is running
- built-in computerised diagnostics
- automatic gradient programming.

The new Du Pont 850 LC is designed to meet the demanding requirements of the research scientist as well as the special needs of the quality control analyst. The chromatographer is in total charge-with authority to change vital parameters without interrupting data reporting.

Human rights in China

MANY Western scientists have experienced the excitement in the past few years of establishing or re-establishing ties with scientists from the People's Republic of China. The openness and frankness of these exchanges (particularly in comparison with the unreal nature of some exchanges with the Soviet Union) has surprised and pleased those involved. Even though there clearly have been and continue to be strong political winds blowing in China, it has been widely anticipated that China will continue to take a fuller place in the international scientific community. But many of the more thoughtful visitors have left wondering what the true price is that the people have to pay to live in modern China. Some inkling of this now emerges from a recent Amnesty International report 'Political Imprisonment in the People's Republic of China'.

The constitution guarantees a number of basic rights, such as 'freedom of speech, correspondence, the press assembly, association, procession, demonstration and the freedom to strike'. In addition citizens have the right to 'speak out freely, air their views fully, hold great debates and write big-character posters'. Furthermore the state 'applies the principle of "letting a hundred flowers blossom and a hundred schools of thought contend" so as to promote the development of the arts and sciences and bring about a flourishing socialist culture'. However, all cultural undertakings must 'serve the workers, peasants and soldiers and serve socialism', and the state 'suppresses all treasonable and counter-revolutionary activities, punishes all traitors and counter-revolutionaries, and punishes newborn bourgeois elements' and 'other bad elements'.

A continuous campaign of purification seems to go on against counter-revolutionary elements, who face a wide range of punishments from public criticism to execution for their crimes of announcing reactionary solutions or writing reactionary posters. Trials leave a lot to be desired; the main aim seems to be to extract a confession, and defence is a rare luxury. Indeed those who refuse to acknowledge their wrongdoing are subjected to much severer sentences. The number of counter-revolutionaries that courts have dealt with is difficult to estimate, but clearly runs into many tens of thousands. Chairman Mao himself once estimated the hardcore of reactionaries at two per cent of the whole population.

The Amnesty report is not cheerful reading; the crude ways in which those who do not follow the official line are humiliated, imprisoned or even exterminated cannot but worry all those who wish to establish the closer diplomatic, cultural and intellectual relations with China. And presumably for every one who runs foul of the judicial system for unacceptable views there are many who simply choose to remain silent. ☐

Research councils dislocated

ON December 18, Shirley Williams, Britain's Secretary of State for Education and Science will officially open the new premises of the Science Research Council and the Natural Environment Research Council at Swindon. This is the final step in a five-year process by which all but a handful of the staff of the two councils have been moved out of London. And the true dimensions of the inconvenience it will cause are now becoming all too clear.

For many of the staff, of course, the move to a more rural environment has had its attractions. Those whose work does not directly involve attending or servicing meetings or being on hand for the scientist who wishes to drop in may well feel that they have gained. But those whose effectiveness depends on easy contact with a wide variety of people have much more reason to complain. In the SRC, for instance, the Chairman's office stays in London, as do the directorates of marine technology and polymer engineering. But the Secretary to the Council is in Swindon, as is the Press Office. Both chairman and secretary are expecting to have to spend an average of a day and a half per week at the other end of the line.

At present SRC council and committee meetings are continuing to be held in London, scattered around the premises of various learned societies. This is hardly an ideal solution, but in the future, wear and tear on council staff may well lead to pressure for more meetings to be held in Swindon, entailing complex cross-country journeys for those who do not live near London, and presumably necessitating more overnight stays. Fine in some respects; if visiting academics and industrialists can be prevailed upon to give up an extra half day, the quality of committee work will probably rise. But it is every bit as likely that attendance at meetings will fall.

Life in Swindon will be fine for a majority of the councils' staff. But the more senior the person, the more inconvenient and tiring it will be. The net result could well be that it will become much more difficult to recruit to the top posts, and that committee members will become much less willing to give of their time. ☐

Crisis for sperm whales

The International Whaling Commission (IWC) is holding a special meeting in Japan next week. Two major tasks for the meeting will be to set catch limits for sperm whale stocks in the North Pacific and to review the status and catch limits of sperm whales in the Southern Hemisphere. John Beddington, lecturer in population biology at the University of York, explains why he thinks no more sperm whales should be caught in these areas.

AT ITS meeting in Cambridge this summer the scientific committee of the International Whaling Commission identified a number of worrying questions concerning the current state of the world's sperm whale stocks. These questions, which were the subject of further discussions when the committee reconvened in La Jolla in November, pose problems both for the whales and the IWC.

Since the 19th century the sperm whalers have concentrated their hunt on the older males, as there are sound economic reasons for preferring these larger animals. More recently it has been recognised that because the sperm whale is polygamous there is a clear opportunity of obtaining an increased yield from populations with a substantially disturbed sex ratio. However, there is a danger that if too many mature males are taken, pregnancy rates will fall as females fail to find mates. This danger is recognised in the current management model used by the IWC which demands that a reserve of socially mature males should be excluded from exploitation to ensure maximal pregnancy. Unfortunately, in two major sperm whale stocks there have been disturbing falls in the pregnancy rates of the female catch. These changes, in the Australian sector of the Southern Ocean and in the Western division of the North Pacific gave a clear indication that all was not well with these stocks.

This problem was illuminated by other scientific analysis by Beddington, Holt, and Fowler which showed that the way in which the IWC had estimated population abundance seriously masked the extent of the depletion of stocks following exploitation. The mechanism involved is simple. The main measure of population abundance used by the IWC is the catch per unit of fishing effort and the measure of effort that has been used was the number of catcher boat days. However, catching whales takes time and daily catch rates at the start of the fishery were limited not by the population abundance but by the time taken for catching whales. Accordingly as stocks declined there was no corresponding drop in catch rates and hence stocks were thought to be more abundant than was in fact the case.

When data for the Western North Pacific stock were reanalysed in the light of these observations it was found that in the period of the observed fall in pregnancy rates the mature male population had fallen below the reserve level and hence pregnancy rates would have been expected to fall. Similar analysis of the Australian stock was not carried out in Cambridge due to lack of time, but some members of the Scientific Committee were of the view that given the substantial fall in pregnancy rates, a similar effect was occurring and that to set a zero quota would be the appropriate response of the commission. In the event this view was not accepted and the quota for this division was reduced by only 25%. Unfortunately, subsequent analysis submitted to the Australian Whaling Enquiry by Kirkwood, Allen & Bannister vindicates this pessimistic view and indicates that here again mature males were reduced below their reserve level and that pregnancy rates would be expected to have fallen. The status of both these stocks gives much cause for concern and it should be noted that as comparable data on the pregnancy rates are not available for all stocks the problem may not be restricted to these areas alone.

A final problem highlighted by the sperm whale analysis concerns the inadequacies of the new management procedure used by the IWC to set quotas. This procedure provides for protection of stocks when they fall 10% below their maximum sustainable yield level. In both the cases considered above, strict interpretation of these rules would permit quotas to be taken—females from the Australian division of the Southern Ocean and both sexes from the Western North Pacific stock. However, simple extrapolation of the demographic statistics indicate that even in the absence of exploitation these stocks would continue to decline for decades. If subsequent analysis corroborates these findings the Whaling Commission will thus be faced with the difficult task of deciding whether to interpret its rules legalistically or to protect these whale stocks. □

Cornelia Durrant, Wildlife Campaigner at Friends of the Earth, UK, adds: At the end of last October it seemed that the UK government had taken some action to protect whales when it announced its proposals for the meeting of the Convention on the International Trade in Endangered Species (CITES) to be held next March. CITES aims to control international trade in wildlife and wildlife products. Those species which the 48 member nations agree are 'endangered' are listed on appendix I of the convention and trade in them is normally forbidden. Those which are considered 'threatened' are listed on appendix II. Trade in them is allowed but monitored.

The UK has been proposing a review of cetacea for next year's CITES meeting. It proposes that 11 species of dolphins and porpoises should be put on appendix I and that all cetacea not on appendix I should be listed on appendix II—including the sperm whale.

When this was announced it received a great deal of attention. So much so that the implications of the UK's other proposal to CITES were not fully explained. The convention requires all 'readily recognisable' parts and products of listed species to be controlled, but there is disagreement over what is recognisable, and many members control no products at all. Together with Switzerland and West Germany, the UK has prepared a list of parts and derivatives of several species of animal which it would like to see all parties control.

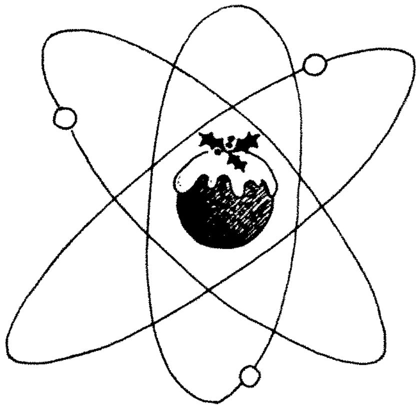
This list, called the 'minimum list' of parts and products, is surprising in many respects. Most surprising of all it does not include whale products because "whale meat, meat products and oil were not considered to be identifiable without the use of biochemical laboratory equipment". However, the UK has always identified whale products for Customs tariff purposes.

Consequently even if all cetaceans are put on the appendices to CITES only trade in live animals will be controlled—and this is only a few dolphins a year. The trade in their products will continue unchecked.

Recent data on the status of sperm whales shows several populations to be more than just 'threatened', in particular those in the Western division of the North Pacific and those in divisions five and seven of the Southern Hemisphere. Consequently there is a strong case for the UK proposing these populations of sperm whales for appendix I of CITES. If, however, the 'minimum list' is accepted in its present form this would be of little use. As it is clearly impossible to distinguish between the products of whales from different populations the only way to ensure that the endangered ones are not further depleted is to control the products of all sperm whales. □

0028–0836/78/0276—0656$01.00

Surprise Christmas present for British science



An unexpected Christmas bonus for British science was revealed this week by the Secretary of State for Education and Science, Mrs Shirley Williams, who announced that the country's science budget was to be increased by more than £47 million over the next four years. More than 70% of this money is to go to the Science Research Council and the remainder is to be divided between the Agricultural Research Council, the Medical Research Council, and the Natural Environment Research Council. Only the Social Science Research Council budget remains static.

The budget increase represents a significant Cabinet victory for Mrs Williams who has been arguing strongly all year for increases in funds for basic scientific research—which, she said, had suffered too severely at the expense of applied research. Now the science budget is to be increased by £10 million in 1979-80; £10 million in 1980-81; £12 million in 1981-82 and £15 million in 1982-83. The move will increase next year's budget to £274 million of which £149.7 million will go to the SRC.

The increase reflected a change in world opinion which was now swinging back to a more favourable view of basic research, said Sir Frederick Stewart, chairman of the Advisory Board for the Research Councils, the body responsible for dispersing the science budget among the five research councils. He quoted recent developments in the United States and France where there had been increases in money for fundamental research.

Mrs Williams said Britain had insufficiently recognised the achievements of its basic science which was regarded highly elsewhere in the world. This extra cash would attempt to remedy this and would also be used to create new research positions for able young students who were now suffering severe problems in finding posts.

Predictably the happiest research council chairman was Professor Geoffrey Allen of the SRC who described himself as "delighted" with his cash allocation. Last month he announced at the publication of his council's annual report that the SRC needed only £20-£30 million to carry out a full but realistic programme of research over the next four years. In fact, the budget increase means he will now have slightly more than £30 million for this programme, of which £4 million will become available next year.

Research allocations

	1979-80	1980-81	1981-82	1982-83
	£m	%	%	%
ARC	24.7	+1.9	+1.1	+1.0
MRC	46.5	+1.6	+0.9	+1.0
NERC	31.1	+2.5	+1.5	+1.0
SRC	149.7	−1.0	−0.5	+1.0
SSRC	14.8	0.0	0.0	0.0
BM(NH)	4.6	+0.5	+0.5	+1.0
Royal Soc	2.6	+1.0	+1.0	+1.0
	274.0			

Initially much of this money will go to restoring the SRC's construction programme to previous levels, including the speedy completion of synchrotron radiation, laser and electron beam lithography facilities at the SRC's laboratories, and also in setting up research programmes in computer and microprocessor technology. It is also hoped that Britain will get a new space programme involving participation in the United States' MMS re-usable satellite project.

As for the other research councils, it is likely that the extra cash will be used on projects including increased research into cancer and its treatment and also to set up a new unit of environmental epidemiology for the Medical Research Council; to improve geological work in deep drilling and mapping for the Natural Environment Research Council; and to support work for the Agricultural Council which would involve developing crops which could fix their own atmospheric nitrogen.

Robin McKie

Blind man's buff at GMAG

On 31 December, the two-year term of office for members of the UK's Genetic Manipulation Advisory Group (GMAG) will come to an end; some members will be leaving and new people appointed in their place. But the criteria used to decide who will stay on and who will leave are a deepening mystery.

The only official information that has been made public about the changes is that Sir William Henderson (until recently Secretary to the Agricultural Research Council) will succeed Sir Gordon Wolstenholme as chairman. A spokesman at the Department of Education and Science told *Nature* last week that in the interest of "balance and continuity", the four sectors represented on GMAG (science, industry, the unions and the public) would continue to be represented and that not all the members of the existing GMAG would be asked to stand down. According to John Morris, GMAG secretary at the Medical Research Council, however, that does not mean that "some members who may wish to stay on will not be sacked".

At least one member of the group, Dr J. R. Ravetz, a public interest representative, can testify to this. Three months ago all members of GMAG were sent a letter asking if they wished to continue. Dr Ravetz, a reader in the history and philosophy of science at the University of Leeds, had played a particularly active role in GMAG and did not wish to leave, but was sent a letter asking him to stand down. He was given no reason other than that new appointments "are necessary to ensure the balance and continuity of the group".

However, two of the three other public interest representatives have indicated that they wish to stand down for personal reasons. Continuity in the public interest sector, Ravetz argues, is therefore being carried on the shoulders of the only remaining public representative, John Maddox. Mr Maddox was unaware that two of the public representatives were leaving voluntarily until contacted by *Nature* last week.

What then are the criteria used to decide which representatives should be removed, and who is responsible for making these changes? For the union and industry representatives, the situation is clear. They are nominated or recommended to stand down by their respective organisations and these recommendations are generally accepted by the DES. The Trades Union Congress (TUC) has asked to be represented on the new GMAG by its four original representatives and by one new member. The four serving TUC members have been reappointed by the DES, but there is no word yet about

0028–0836/78/0276—0657$01.00

the request for a fifth representative. The Confederation of British Industry has requested that its representative Mr John Gilby, be renominated and is awaiting a reply.

The situation of the science and public interest representatives is, however, considerably less clear. They are directly appointed by the DES but there appears to be no set procedure governing these appointments beyond "usefulness to the group". Ravetz has certainly been useful, but he has also not shrunk from expressing his opinions, and he may have been seen by some close to GMAG to be 'rocking the boat'.

According to one DES spokesman, the public interest representatives are the ones most likely to change "because the scientific specialists are a small group to choose from", but he expects that the overall "mixture of representatives" will remain the same—except that possibly a lawyer will be included on GMAG for the first time As to who at the DES is responsible for the changes on GMAG, several sources indicate that Shirley Williams, the Education Secretary, is taking a direct and personal interest in the new appointments. However, her advisers on GMAG remain in the shadows and do not appear to include GMAG's existing members

All this might be unimportant if it were not symptomatic of how GMAG handles its external relations. And external relations are important to a body whose decisions can affect the competitiveness of British biotechnology industry overseas. In this context, it is obviously desirable to get GMAG's standards accepted and applied by other countries. Unfortunately GMAG does not appear to communicate effectively with foreign scientific organisations. There is a strong feeling among some European scientists that GMAG could provide greater leadership in Europe by revealing more details of its work. As Dr Ravetz argues: "in about a year an American GMAG could be established that would operate in public and be easily accessible to foreign scientists. If that happens, the British GMAG would probably be ignored rather than be viewed as a model for all the world".

A. J. McClelland

Difficulties at PETRA worry designers of Europe's next accelerator

PETRA, the world's biggest storage ring for colliding electrons with positrons, is not behaving quite as expected, writes **Konrad Guettler**

THE European Committee for Future Accelerators (ECFA) convened its technical panel on the design of LEP—Europe's proposal for a 70 to 100 GeV electron and positron storage ring—in Rome recently, only to hear that the machine of which much LEP design has been based (West Germany's 19 GeV PETRA) is encountering difficulties.

Although PETRA started up very smoothly, ahead of schedule, and soon achieved beams of long lifetime, its luminosity (which determines the rate at which experiments can be done) is at present a factor of 100 or so below design The profound worry is that the scaling up of parameters from lower energy machines, such as the 10 GeV DORIS and SPEAR, to the very much higher energies of PETRA or LEP may in fact not be straightforward, or indeed possible at all It is still early days for PETRA but a large investigation program on both the technical and the theoretical side has now been launched both at DESY and by ECFA.

Nicola Cabbibo, a particle theorist at Rome University, and CERN are directing the attempts at increasing theoretical understanding of the observed beam properties. The main effects are the following:

- the maximum beam-beam tune shift 'ΔQ' is much less than its design value. ΔQ is the major factor, apart from the stored particle current, determining the machine luminosity, ie the number of interactions that take place at an intersection in unit time. The tune shift is a measure of the non-linear transverse forces between colliding bunches. All the existing machines turned out to have the same limiting value; and this ΔQ had also been assumed for PETRA and for LEP.
- Fast beam instabilities occur at various stored currents and appear to depend on the accelerating radiofrequency voltage. The circulating beams induce currents in the vacuum chamber walls and these wall currents create fields which interact directly with the beam. They can alter the normal betatron and synchrotron frequencies of the beam and thus cause instabilities.
- The accelerated bunches are larger than expected. (This affects the long-term beam stability.) Bunch lengthening is again due to the short-range fields induced by the bunch in the wall It leads to a wider energy spread within the bunch and can lead to head-tail instabilities.

There was a lot of concern at Rome that there was inadequate knowledge of beam dynamics at high energies. But a lot of experience is accumulating about high energy electron-positron machines and there was a widespread hope that while machine physicists have encountered very tricky problems indeed, they are unlikely to lead to profound revisions in the approach to LEP.

Since ECFA's Rome meeting, PETRA has run continuously and machine physicists have now pushed the beam current to a maximum of 18mA per bunch, almost up to the 20mA limitation design value. The previous current limitations have been overcome by changing the injection optics to the type also proposed for LEP The present aim is for fast injection and a high beam intensity, and only later will PETRA go for higher energy, and hopefully, higher luminosity. The latest machine runs at a centre-of-mass energy of 16 GeV have yielded 1-2 hadronic events per nanobarn cross-section per day—which can be compared with 20-100 events at DORIS. This is not a very high luminosity; but the DESY machine physicists are confident about increasing it Higher energies have to wait till next year when additional accelerating cavities will be switched in. □

Keeping down the cost of LEP

HIGH-ENERGY physicists have become very aware of current financial constraints, and are paying a great deal of attention to reducing the cost of LEP, without diminishing its physics potential. CERN has estimated the construction cost of a 70 GeV LEP to be a little over 1,000 MSF, which is almost the same as the SPS proton accelerator built at CERN a few years ago. No decision about the project has been taken, but ECFA hopes to present a detailed design study to the CERN Council by the end of 1979.

The physics interest in LEP is focussed on the maximum energy of the machine Lepton physics at high energies centres around the role of the intermediate vector bosons, the charged W^+ or W^- and the neutral Z°

Their masses can be estimated from the 'Weinberg angle' measured in neutrino interactions. At present predictions of the Z° and the W^+ mass are 89 ± 5 GeV and 78 ± 6 GeV, respectively. Single beams of about 45 GeV should be sufficient to produce Z°s in association with other particles but the full machine energy will be required to create a W^+W^- pair.

For technical and cost reasons, the original CERN design study (LEP-70, completed this summer) was optimised for an energy of 70 GeV; but it is now being redone for 80-85 GeV per beam. The size and cost of any such machine increase with its maximum energy, and LEP-70 already had a circumference of about 30 km. However, valuable experience was gained from the LEP-70 design exercise. In particular the cost sensitivity of machine parameters and components can now be assessed more reliably.

Wolfgang Schnell, of the CERN ISR division, has already proposed some interesting ways of reducing the construction cost of the future accelerator. LEP will have more than 2,500 dipole bending magnets to keep the particles on their orbits. The bending power of each magnet is low because too high a track curvature would make the electrons lose too much of their energy by synchrotron radiation. Conventionally, magnets are made by precisely stacking hundreds of thin steel plates and welding them together. But the low magnetic fields required for LEP (to reduce bending, synchroton radiation, and running costs) can be obtained by bonding a smaller number of steel plates in concrete, thereby dispensing with a lot of steel and fabrication cost.

Further, the particle beams have to be refocused repeatedly to counteract the natural tendency of beams to diverge. More than 800 quadrupole magnets are foreseen for this task. A similar number of higher multipole magnets completes the set of tools which allow machine operators to tune the beams and to overcome instabilities. Using anodized aluminium in the manufacture of quadrupole coils, in place of copper, would save much cost and production effort; detailed investigations into the properties of such coils are already under way.

The costliest item of the machine is the radio-frequency system which will accelerate the electron beams. Its components, klystrons and accelerating cavities, stretch over 1.5 km and their total power consumption at 70 GeV will be over 70 MW. About 19 MW of this will simply be lost in synchrotron radiation, a feature which is negligible in all existing proton accelerators. When a bunch of electrons passes through the cavities, it picks up energy from the applied RF power and thus is accelerated. But the four bunches in each beam spend most of their time outside the accelerating cavities, and the applied power is lost. An ingeneous method to reduce these losses is to couple a low-loss mode storage cavity to a set of accelerating cavities. Energy can then be saved by constantly transferring power between the accelerating and storage cavities.

By itself, this scheme would not help on component cost but it would either reduce running cost, or alternatively allow a higher maximum beam energy. superconducting RF cavities is cur-to become available in a few years' time; they will eventually allow the beam energy to be raised to about 130 GeV. The upper limit is set by the synchrotron radiation power that can be absorbed by the vacuum chamber, and by the field gradient ilmitations in the accelerating cavities. Research into super conducting RF cavities is currently carried out under a joint CERN-DESY programme, and a first test cavity is to be installed into DORIS by the end of 1979. However, it is unlikely that this technology will be sufficiently mastered for mass production for the first phase of LEP.

Great importance is also attached to the planning of experimental installations and facilities. Experience at DORIS and SPEAR has shown that the cost of experimental detectors and associated electronics and computers amounts to a sizeable fraction of the total machine cost. Furthermore, the average number of charged particles produced in an electron-positron annihilation at these energies is of the order of 20. Very complex detectors are required to track that many particles, and to identify them unambiguously. So a major effort must be made to reduce the cost of such devices.

Konrad Guettler

Fermilab looks to the future

David Dickson visits the Fermi National Laboratory and talks to its new director, Dr Leon Lederman (right)

THE past year has not been an easy one for the Fermi National Laboratory)Fermilab) at Batavia, just outside Chicago. Twelve months ago Fermilab's then director, Dr Robert R. Wilson, was pushing hard for the rapid completion of the next phase in Fermilab's development. This is to be the construction of a second ring of superconducting magnets which, with their increased field, will allow energies of up to 1,000 GeV to be reached, twice existing energies.

Last November, frustrated by indications that the Department of Energy would not provide him with sufficient funds for the rapid construction of the Doubler, Dr Wilson threatened to resign if such funds were not included in Fermilab's budget for the fiscal year 1979. But the department stood firm, providing Wilson with only $15 million of the $30 million that he had requested. And in February he resigned as threatened, citing the department's "indecisive and "subminimal" support for the Doubler project.

The whole affair left the US high energy physics community feeling somewhat uncomfortable. Many of those who had admired Dr Wilson's achievements in establishing Fermilab were uncertain about the strategy that he had chosen to adopt. Dr Wilson also left a legacy at the laboratory where many felt experimental programmes had been unfairly squeezed to allow development work on the Doubler to proceed as rapidly as possible.

The task of putting all the pieces back together again now rests with Fermilab's new director, Dr Leon Lederman, whose appointment was announced in October and who takes over the position full-time next 1 June (although already working several days a week at the laboratory).

Dr Lederman is currently professor of physics at Columbia University and director of the university's Nevis accelerator. He has also been closely involved with Fermilab since its inception; he was a member of the team which selected the site from over a hundred possibilities in the 1960s, and he also led the investigators who discovered the upsilon particle in the summer of 1977.

0028–0836/78/0276—0659$01.00

Widely known not only as a successful experimentalist but also the owner of a quick wit—asked where the laboratory is going, his immediate response is that "It's going to stay in Illinois—I hope"—Dr Lederman has few illusions about the problems that lie ahead.

At the heart of many of these lies the issue of funding. Tight budgets have squeezed high energy physics as hard as other fields of science. Dr Lederman says that "basic research is being treated rather well by this administration"; but he points out that with three large accelerator projects now under way, the whole US high energy physics programme is "pushing very hard against its ceiling", and that "if the budget was even 5% higher, it would be an enormous relief".

High risks

The Energy Doubler will require a ring of 1,000 superconducting magnets, each 7 metres long. Although recognising that, with so little known about such technology, the field was one of high risks, Dr Wilson felt that the design of the magnets could be refined as the first ones were being produced (rather than waiting for a complete design before setting up production facilities).

However the gamble did not quite come off. Technical problems proved to be slightly greater than initially predicated—such as a slight movement in some of the wires of the coils, affecting their superconducting properties—and took longer than anticipated to perfect.

As Dr Lederman puts it: "There were some concepts in economy that were not realised. We had thought that a much larger fraction of the original magnets would be adequate and that we would be able to instal those to make up one sixth of the ring. But not enough of them were of good quality; and that created a problem with funding".

Dr Lederman places stress on the need to maintain a high level of performance, not only with the Doubler but also with the existing accelerator. "We have at present a responsibility to provide a large fraction of the US high energy research community with 400 GeV protons. I have found attention to the programme has slipped somewhat and people have been travelling here from the East coast and the West coast and waiting for a machine that was broken down a bit too often."

With development work on the Doubler's magnets now completed, a team at Fermilab is now preparing a final detailed design of the accelerator, which is expected to be ready in January.

Until a few years ago, many of Fermilab's problems might have been solved by a quick visit to sympathetic Congressman, with a few million dollars subsequently added to budget appropriations. But this style of approach is no longer appropriate, particularly as the decision making role has shifted from the old Congressional Joint Atomic Energy Committee—which produced much of the political support for early accelerators—to the Department of Energy's High Energy Physics Advisory Panel (HEPAP).

Earlier this year Dr John Deutch, director of the department's office of Energy Research, announced that the Office of Management and Budget had accepted a proposal to provide high energy physics with a constant budget over the next few years. Within this limit, the department has left it largely up to HEPAP to advice on how the resources should be allocated; the result is that any major development requires the active backing of HEPAP if it is to get support in the administration.

"One of our current very high-level efforts is therefore to bring the physics community into a level of acceptance, understanding and support of the Doubler project", says Dr Philip Livdahl, head of the project and currently acting-director of Fermilab.

Dr Lederman has already asked for an outside, independent review of the whole Doubler project, and has invited scientists both at Fermilab and in the universities to present ideas for the type of experiments that they would like to carry out when the 1,000 GeV level become available with the completion of the new ring.

A number of such ideas were discussed at a meeting of HEPAP which was held at Fermilab at the beginning of last week. It is said that the exercise had a beneficial effect on some of those who still have doubts about the Doubler project. The advisory panel has now asked the laboratory to prepare a detailed report on the ways in which the Doubler construction programme might be integrated with other activities, setting out the option at different budget levels so that it can assess the requests for greater support.

Colliding with Japan

From Fermilab's perspective, HEPAP's support is likely to be particularly important next year, since it is hoped that funds to begin construction of a colliding beam facility—involving collisions between particles in the existing ring and those circulating in the superconducting ring—can be included in the Department of Energy's budget request for 1981.

One bright spot on the funding horizon is the proposed collaboration with Japanese scientists. High energy physics figures prominently in a programme of research collaboration in the energy sciences between the US and Japan that could be worth $ 1,000 million over the next ten years.

Collaboration in high energy physics will take place at three different levels: carrying out joint experiments on existing facilities, joint research and development in accelerator design and technology, and—potentially the most ambitious point—funding of new facilities.

In the first category, Dr Lederman hopes the Japanese contribution will add those few percentage points to the research budget which would have a magnified effect on scientific productivity. As to the third, Japanese funds could help bring forward some of Fermilab's more long-term plans: in particular, the development of facilities for the production of high-energy anti-protons which could be injected into the same ring as the protons, but circulating in the opposite direction to give collision energies of 2,000 GeV.

World Machine

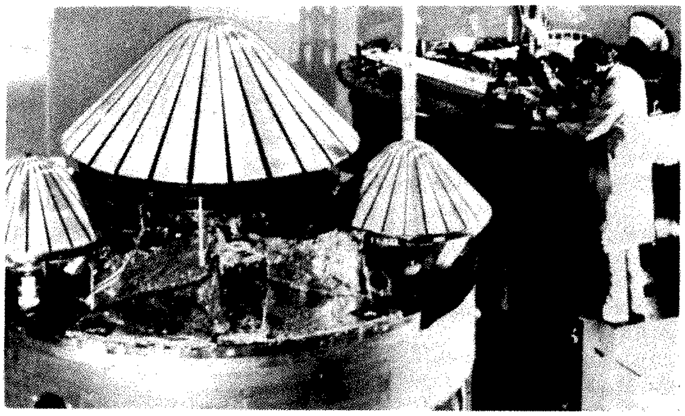
And there is an interest in high energy physics not only in Japan, but also in the Republic of China, which has recently sent a number of scientists to study at Fermilab. Dr Lederman has been closely involved in the activities of the International Committee for Future Accelerators, and in particular its scheme for the possible construction of a "world accelerator" in the 20,000 GeV range (20 TeV), well beyond the economic scope of any one country.

"When we started there were only three areas of the world interested in the possibility of such a project: the US, the USSR and Western Europe. With three there are problem of cooperation; but with five the situation is much better, since it does not matter too much if one decides to drop out"

Dr Lederman is also understandably enthusiastic about the particular possibilities raised by the Japanese connection, and is a member of the Department of Energy working party which has been discussing details of the proposed collaboration between the two countries with Japanese scientists.

He feels that high energy physics could play an important role in Japanese society. "Talking to Japanese politicians and ministers, they seem to feel the lack of intellectual heroes, the role played by Einstein, Fermi, Newton and so on in the West. They do not have that heritage to inspire the young people." High energy physics, Lederman belives, might provide the inspiration. □

news in brief



Before the launch: checking out the probes that have now surveyed Venus's atmosphere.

Exploration of Venus: Ten spacecraft—six American and four Russian—are exploring Venus this month. One spacecraft, the US Pioneer Venus I, went into orbit on 4 December and is expected to be operational for at least a year. Five other US probes for exploring the Venusian atmosphere penetrated the atmosphere on 9 December and transmitted data during their hour-long descent to the surface. They were not expected to survive the crash landing, though one continued to radio information back to Earth for an hour after reaching the surface. The probes contain instruments to measure density, pressure, wind speeds, heat flow and atmospheric composition.

Meanwhile, towards the end of December, two Soviet spacecraft will "fly-by" Venus, and each is expected to release a lander. These landers are intended to survive for a short period on the surface of the planet and take photographs of their landing site. The instruments on the Soviet probes will need to withstand the extreme conditions on Venus: atmospheric pressures 100 times that on Earth, high concentrations of sulphuric acid in the air and temperatures of nearly 500 °C.

"Anti-intellectualism" hits US basic research: Federally-supported basic research in the US is feeling the edge of a definite anti-intellectualism in some sectors of American public opinion, according to Dr Richard Atkinson, director of the National Science Foundation, in a speech at the University of Indiana. He added, however, that, in supporting those who attacked esoteric-sounding research programmes, the public seemed to be demanding some assurance that Government-supported activities were connected with real human concerns and problems. "The scientific community will be far more likely to gain acceptance by dealing with these concerns in a patient and serious way than by reacting in an ill-tempered or patronising fashion."

Dr Atkinson, whose agency received a budget cut in Congressional committees that reduced the growth of its basic research to below the level of inflation, said that the importance of basic science to the economy was now being recognised in China after the Gang of Four's hostility to scientists and scholars. "The Chinese experience should be a sobering reminder to all of us, scientists and non-scientists alike, that intellectual creativity is every bit as significant as a measure of a society as military strength or economic output," he said. "It seems somewhat paradoxical to me that the present Chinese leadership has grasped this lesson so thoroughly at a time when American opinion seems increasingly uncertain of the value of basic research and scholarship."

European control of genetic manipulation: Guido Brunner, EEC Commissioner for science and technology, has suggested that the Community should formulate rules to cover the experimental and industrial use of genetic manipulation. All such work would have to be notified to the national authorities of the member countries, he said. At the moment, Britain is the only one which requires notification, but others are planning to introduce legislation. A spokesman said the Commission was only at the stage of talking about the proposals, and it is not known if it intends to set up a committee similar to Britain's Genetic Manipulation Advisory Group.

Government calls for cut-backs in animal experiments: Scientists in Britain are being urged by the government to restrict the use of living animals in experiments. In a letter to all scientists in the country licensed to carry out experiments on living animals, the government says the experiments should be "limited to the minimum compatible with the pursuit of legitimate scientific ends". The letter stresses the importance of finding alternative methods of conducting scientific experiments, such as tissue culture or computer modelling. Scientists are asked to take "every reasonable step to confirm, before using living animals, that their investigations cannot be done by any alternative means".

The government hopes scientists will be encouraged to develop new alternative techniques. But, Dr C. Stratmann, scientific consultant to the Fund for Replacement of Animals in Medical Experiments (FRAME), said: "We are concerned that little funds are available specifically to find alternatives." Over the last ten years, FRAME has built up a library of information and literature on alternatives. Dr Stratmann urged scientists to contact FRAME if they wish to find out about alternatives.

The number of experiments on animals has remained fairly constant over the past eight years—at about 5.5 million experiments a year, according to government statistics on animal experiments published last Thursday. Over half of the experiments were carried out for commercial reasons such as drug and cosmetic testing.

Inquiry into extension of Natural History Museum: The government has called for a public inquiry into the Natural History Museum's plans to build a new wing known as the East Infill Block. The plan has aroused public interest because it involves demolishing part of the original Waterhouse building, which is listed as of historical interest. Although an inquiry is not required by law, the government wants everyone concerned to have a chance to put their case.

Pesticides in the diet : The average British diet still contains unacceptably high levels of Dieldrin, a pesticide used against woodworm, according to the latest report of the Government Chemist. Although the level of Dieldrin in the diet is less than half the Acceptable Daily Intake recommended by the World Health Organisation, it has not declined in recent years, despite increased restrictions on its agricultural use. Dieldrin is one of the most poisonous organochlorine pesticides, especially as it is not metabolised by the body.

The persistence of Dieldrin in the diet suggests that it may come from a non-agricultural origin. In an isolated incident earlier this year, 4,000 chickens died in East Anglia after eating litter containing wood chips treated with Dieldrin. Government chemists, therefore, began an inquiry into whether some cattle feeds made from dried poultry litter could be a source of Dieldrin in milk.

How molecular biology won its place in the USSR

PROFESSOR Lev Tumerman, who played a leading role in the fight against Lysenkoism, emigrated from the Soviet Union to Israel in 1972. Since then, he has been prominent in the press discussion of the Kyshtym nuclear "disaster" of the 1950s. Vera Rich talked to him recently at the Weizmann Institute, where he now teaches.

PROFESSOR Tumerman was originally a physicist. He later turned his attention to molecular biology—a change which, he explained, reflected the whole story of his life in Russia.

Owing to the stress placed by Soviet defence policy of the early 1950s on the atomic bomb, physicists enjoyed what was, for those days, a relatively privileged position. They had greater freedom of action than other scientists and according to Tumerman, played a leading role in the fight against Lysenko.

In the early 1950s a number of physicists became interested in molecular biology and started working underground. Frequently, said Tumerman, the physicists acted as hosts to such unauthorised gatherings. "Timofeev-Resovskii's first lecture on genetics was given in Kapitsa's Institute of Physical Problems", he said. "I myself organised the first seminar on genetics at the Lebedev Physical Institute. We had about 200-300 participants at every meeting of the seminar. This was the first legal seminar on genetics. The time was ripe to begin the fight".

Many famous physicists, including Kurchatov and Tamm, were by now interested in molecular biology, and the pressure was kept up in many forms. An underground seminar was held every year in the Ilmensk nature reserve.

By this time, Professor Tumerman's interests had switched almost completely to molecular biology, although this change was not reflected in his official work. "Before my arrest", he explained casually, referring to his seven years in solitary confinement, "I had worked for 20 years with Sergei Vavilov, as a pure physicist. (Sergei was the brother of Nikolai Vavilov, you remember, who perished during the Lysenko period). We worked together from 1926 to 1947 on fluorescence as a physical phenomenon. The first fluorescent lamps in Russia were made by my hands."

Genetics—learnt in gaol

"In the Vladimir prison, there was a very good library—built up from books confiscated from the homes of prisoners. I began to read books on genetics. There was one very good book by Sunnot and Dent. These books impressed me so much that after I was released I changed my field of interest. I felt that purely physical phenomena were no longer of interest to me. I could only work at the interface of physics and molecular biology. I wanted to understand the role of physics in biological processes. So from 1954 to 1958, I worked at the Lebedev Physical Institute, but I changed my field of activity to photosynthesis. This was my official work, but unofficially I was interested in the whole problem of genetics and molecular biology."

In the seminars which Tumerman and his fellows organised, little could be done except to present and review the results of foreign papers. Yet, although no experimental work could be done at that time in molecular biology, Tumerman sees the seminars as far from fruitless. "We felt it was very important to involve young people in this field—to give an impetus to press the authorities. And in 1958 we won our victory, and molecular biology was allowed to exist officially."

As an immediate consequence of the new policy, Academician Engelhardt was given the task of setting up a new Institute of Molecular Biology, and Tumerman himself was invited to be head of the Laboratory of Bioenergetics. This laboratory investigated a number of problems, including nucleic acids and photosynthesis; Tumerman's own work was an attempt to apply physical mechanisms to problems of molecular biology.

"During the last few years", Tumerman added, "genetic engineering has evolved. But this came up after I had emigrated and I know nothing about it. I never worked on military applications. It was not easy for me—they often pressed me, but I managed to stay clear of military problems."

Yet although his own work remained unclassified, Tumerman did in fact come into possession of certain data which, whether technically classified or not, the Soviet authorities clearly wanted to keep secret. This was the story of the Kyshtym disaster.

"In the early 1960s", explained Tumerman, "Timofeev-Resovskii was working at the Inmensk nature reserve on the action of radiation on plants, and there was certainly no contamination there". (This is the nature reserve where the clandestine meetings on molecular biology and genetics had been held.)

At that time, Tumerman's brother was working as a construction engineer on the new atomic power station at Beloyarsk, some 100 km away. One day, Tumerman set out to visit his brother by car, leaving at midnight. "By 5.30 it was light", he recalled, "and I saw a sign by the road 'No stopping for 25–30 km'.

"On both sides there was *mertvaya zemlya* (dead land). No villages, only chimneys—the houses had been pulled down to keep the people from returning".

Asked to clarify the expression *mertvaya zemlya*, Tumerman explained that by 'dead land' he did not mean there was any signs of devastation. The land was simply empty—no agriculture or any other sign of land-use. "The local people said it was due to a 'catastrophe' at Kyshtym", he said. "I don't have any knowledge of its cause or nature. It had been some years before. I assumed that some waste must have fallen and that the level was so high that the people had had to be evacuated and many hundreds of square kilometres of land left free from cultivation".

Keeping quiet about Kyshtym

Tumerman at first made no attempt to publicise this knowledge. Only when, some years after Tumerman settled in Israel, Zhores Medvedev began to draw Western public attention to the disaster, did Tumerman begin cautiously to publish what he knew.

"I was afraid," he explained, "that people would use the story to interfere with the building of atomic power stations. I believe that the building of atomic power stations—real power stations, not plutonium processing plants—is the prime necessity for mankind. We must be prepared that in maybe 20 years the oil will run out. And world politics will change. No one will be interested in the Middle East".

"I published my account", he insisted, "to prove that the danger is not in atomic power stations. Atomic power stations are the safest form of energy production, much safer than oil".

However one accepts this estimate, Professor Tumerman's assertion that Kyshtym was not due to some power station disaster seems, on the face of it, irrefutable. For at the time when he passed through the devastated area, he was on his way to visit his brother at Beloyarsk, where the first atomic power station in the Soviet Union was "only at the first stage of building". "So whatever caused the disaster", Tumerman concluded, "it simply could not have been connected with any power station!" ☐

On cave paintings and nuclear security

By Alvin Weinberg, director of the US Institute for Energy Analysis, Oak Ridge, Tennessee

Dr J. Altuna took well-justified pride as he showed us the cave paintings in the Ekain caves near San Sebastian that he and his colleagues had discovered in 1968. The horses (pictured above) by some Cro-Magnon genius 11,000 years ago were in every respect remarkable: according to Dr Altuna, the best cave paintings of horses to have been discovered to date. The paint we now see is largely manganese dioxide which was probably mixed with animal grease to apply it to the wall.

I was in the Basque country at the invitation of Aranzadi, the Basque Scientific Society. I was to participate in a discussion of nuclear energy with Professor Erik Arrhenius of Sweden. My reaction to the cave paintings, aside from astonishment at the skill of the artist, was therefore coloured by the nuclear debate. Could these artefacts of man, some of which have lasted as long as 11,000 years with little deterioration, bear on the disposal of nuclear wastes? Dr Altuna was very doubtful—after all, not all the paintings are in perfect condition. On the other hand, some were; and in the absence of proof of the unprovable—we cannot know *absolutely* the fate of geologically sequestered wastes 10,000 years from now—we can draw inferences from long-lasting artefacts of man. Herbert Muller, in his *Freedom in the Ancient World*, speaks of the ancient cave-artists as having "unconsciously . . . worked for posterity". In this instance they have, unwittingly, proved that at least some works of man can survive for immensely long times; 11,000 years is sufficient for the radioactivity in wastes to fall below that of the original uranium ore whose fission gave rise to the wastes. And if *some* artefacts can last that long without change, is it not more plausible to believe that we, who are more sophisticated than our Cro-Magnon ancestors, can reproduce the necessary conditions for survival of solidified wastes than that we cannot?

Ekain, or the 30,000-year-old stone Venuses, or, for that matter, the 2,000-million-year-old natural reactors at Oklo in Gabon add to what I believe is already convincing evidence that waste disposal is tractable. The issue ought not to be used as an argument against the use of nuclear power, despite the controversy that once again rages over the feasibility of waste disposal.

Rather, the central argument, and the one that I suspect all the other issues will coalesce around, is the peculiar requirement for institutional stability demanded by nuclear power. It is therefore ironic that just 30 kilometres from Ekain, with its evidence for the technical feasibility of waste disposal, lies Lemoniz, a prime reminder that nuclear energy and social instability don't mix. About a year ago, a main steam generator in one of the pressurised water reactors under construction at Lemoniz was bombed by Basque terrorists; and a terrorist was killed in a shoot-out with guards at the construction site.

The Lemoniz incident was not primarily anti-nuclear: it was rather that Lemoniz (above right) was sited under the Franco regime without much consultation with the local Basques. It had become a symbol of Basque nationalism: in the view of many Basques, Madrid was imposing its will on them.

This essentially political objection to Lemoniz provides fertile ground for anti-nuclear activism. And in the colloquium, Professor Arrhenius and I were bombarded with the same questions I encounter everywhere: waste disposal, reactor safety, proliferation, low-level radiation effects.

The Basques are of two minds about Lemoniz. On the one hand, they see it as imperialist intrusion. On the other, they sense that nuclear stations, rather more than, say, oil-fired stations, confer a degree of energy autarky. Once the Lemoniz reactors are built, the Basque country will have a large source of electricity entirely within Basque borders. A precondition for this additional degree of energy self-sufficiency, I pointed out to the Basques, is an end to nuclear terrorism. Once Lemoniz is operating and its core contains billions of curies of radioactivity, it must be judged out of bounds for would-be terrorists: a core meltdown induced by terrorist action would harm the Basque country more than anywhere else.

Would the presence of an operating reactor mitigate the scope of action of terrorist groups—at least to the extent of putting nuclear plants out of bounds? I should think this might be the outcome in the Basque country where terrorists and local population presumably have the same aim—more autonomy for the Basques. Once Lemoniz is operating, one would expect terrorist acts against it to cease. I am less sanguine about nuclear terrorism in other situations where the terrorists may have no motive except destruction of the existing order. The only safeguard against such terror is heavy security. It is no accident that Lemoniz is as closely guarded as any US atomic weapon establishment. But these security measures are confined to the reactor site, and to speak of such measures as implying a police state seems to me to be an absurd exaggeration. Heavy security against terrorists is a price that nuclear energy exacts; fortunately, the number of places that will have to be so guarded is small, and they pose little threat to the society as a whole. I would hope that nuclear plants everywhere are made as secure as Lemoniz now is. ☐

Good and bad Nobel prizes

SIR,—The Soviet authorities and mass-media are distinguishing between 'good' and 'bad' Nobel prizes. A Nobel prize is a good one and means great and deserved recognition for the USSR, if it is awarded to an obedient and loyal Soviet intellectual: to the writer Sjolokhov, to the physicists Basov and Prokhorov, to the chemist Semjonov or the economist Kantorovich.

The Nobel prize is a bad one and is a provocation of western imperialists and international reaction, if it is awarded to some of the Soviet writers or scientists, who are on the 'banned' index; say Boris Pasternak, Alexander Solzhenitsyn or Andreii Sakharov. Pjotr Kapitsa's recent Nobel prize for physics is considered good by Soviet authorities and mass-media.

Professor Kapitsa is no doubt a great and famous scientist. He was awarded the Nobel prize for a discovery he made 40 years ago in Moscow with equipment which had been sent to him by his professor, Ernest Rutherford, from Cambridge. But is this year's Nobel prize really a good one for the Soviet Union? Does Pjotr Kapitsa really belong to the obedient and loyal Soviet intellectuals?

The facts of his life suggest the opposite. The young Soviet physicist came to Cambridge in 1921 and in a few years became Rutherford's most respected collaborator and expected successor in the Cavendish Laboratory. In 1934 Kapitsa left for a vacation in the Soviet Union and unexpectedly was prevented by Soviet government from returning to Cambridge. The Soviet government offered him a new institute in Moscow without any financial and administrative restrictions.

Rutherford had been trying very hard to get his collaborator back, but when he finally saw the vanity of his attempts, he finally decided to make a beautiful gesture: he sent the equipment of Kapitsa's recently-built Mond laboratory to Moscow. Kapitsa had just completed the equipment before his departure on vacation.

Kapitsa had his institute in Moscow, an important position in the Soviet academy of sciences, and a considerable influence in the government when, in 1939, another of the future Nobel laureates and his close friend Lev Landau had been arrested. Kapitsa came to the Kremlin and presented an ultimatum: if Landau was not released, Kapitsa would leave his institute and stop his work. This was a risky step, but the Soviet government needed Kapitsa. Landau was released and his life saved.

In spite of all this Kapitsa was himself a privileged prisoner. Until the late fifties he was not allowed to travel abroad, his contacts with foreign scientists were restricted, and his correspondence often confiscated. Kapitsa became a prisoner in his country house at Nikolina Gora in 1945, when he fell out with Stalin over the problem of Soviet nuclear weapons. He was released from prison only after Stalin's death and only then was able to resume his directorship in the Institute of Physical Problems.

Kapitsa never hid his critical attitude to the Soviet reality, nor his sympathy with those who openly oppose this reality. "How many roubles would our finance ministry release to Rembrandt for the brushes, how much for the canvas and how much for the colours?" says Kapitsa, chiding administrative restrictions confining Soviet science. "On 20 February 1956 an instruction was issued, according to which all directors of academic institutes must present a plan of every single working day for the approval of the academy. But I, for example, cannot plan every single working day, say when I will be sitting in the laboratory and when in my studio—this depends on how our investigations will proceed . . ."

Very sharply, and often, Kapitsa criticised the backwardness of Soviet science, its low productivity. In 1965 the USSR and USA had approximately the same number of scientists, but the USA did about one-third of world science, and USSR only one-sixth. "Therefore, no matter how sad it may sound, we have to admit that the productivity of our scientists is two times lower than that of Americans."

Andreii Sakharov is a good friend of Kapitsa, and so are many other Soviet dissidents. Kapitsa was one of the initiators of the public protest which helped to release Soviet biologist Zhores Medvedev from psychiatric prison. His signature was among the few tens demanding the abolition of the death penalty in the USSR. And his villa in the institute park is a frequent meeting place for dissident Soviet intellectuals. The atmosphere inside is stimulating: in Kapitsa's studio hangs a photograph of Solzhenicyn, with his handwritten dedication.

When the Soviet sculptor Ernst Neizvestnyj was expelled from the USSR in 1974, Kapitsa gave a farewell party for him in his house. In the presence of many guests he made a toast, in which he said: "I have to admit that I envy you a little bit. You are young and you will live to the time when you could come back to Moscow. And you will walk on the Solzhenitsyn square, and on Andreii Sakharov prospect, and the street where you will have your atelier will bear your name. But I am already old and will hardly live to see it . . ."

Eighty-four years' old academician Kapitsa may really not live long enough to see such changes in USSR. But when they finally come, nobody will deny his merits.

This year's Nobel prize for Pjotr Kapitsa is, therefore, not quite a 'good' prize for the Soviet Union. But is more than a highly deserved prize for an old professor.

Heraclitus Revisited

SIR,—You may be interested in these lines stimulated by the review of Erwin Chargaff's new book (*Nature* **276**, 133; 1978):

I'll tell thee everything I can:
  There's little to relate.
I met an old, embitter'd man
  Bemoaning his sad fate.
"Who are you, aged man?" I said,
  "And what is your pet peeve?"
His answer trickled through my head
  Like water through a sieve.

He said "I met a fervid pair
  Who built a model crude
The younger one had lengthy hair
  And both of them were rude.
They claimed that they were out to find
  What makes genetics tick
And when I call the scene to mind
  The mem'ry makes me sick."

But I was thinking of a plan
  To write a grant request
And if the funding once began
  I'd count myself well-blest.
So, having no reply to give
  To what the old man said
I cried "Come tell me why you grieve"
  And thumped him on the head.

He said "The times are bestial
  The world has gone to hell.
My culture is celestial
  In science I excel.
Of Mozart's symphonies and themes
  I know the form and keys.
I dream the most exalted dreams
  Of any Viennese."

But I was thinking of a way
  To cut him down to size
By noting what he had to say
  Was something less than wise.
And then I wondered if these lines
  Would capture his attention
Because his musings show some signs
  Of scanty comprehension.

And so if e'er by chance I put
  My fingers into glue
Or madly squeeze a right-hand foot
  Into a left-hand shoe
Or if I drop upon my toe
  A very heavy weight
I weep, for it reminds me so
Of that old man I used to know
Who seems distracted with his woe,
Who mumbles of the long-ago
As if his mouth were full of dough
  Bemoaning his sad fate.

Homo erectus

SIR,—I was very pleased to see that due recognition was given to *Homo eructus* in the item on East Javan hominids (28 September, page 306).

Few, indeed no, previous commentators have given this hominoidal form sufficient weight, although his more commonly used name gives a clue to his place in taxonomy: just a breath away from Pe-King Man must come Bel-Ching Man.

His undoubted place as a direct ancestor of *H. sapiens sapiens* is attested by *H. eructus'* easily identified descendants in any group of humans today.

However, I have been greatly puzzled over how his patronymic attribute has been deduced from skeletal evidence.

Solar energy storage and conversion by hydrogen cycle

from Robert W. Cahn

All forms of 'current' energy—Sun, winds, waves, tides—are intermittent and variable and their use for large-scale and domestic purposes alike demands provision of energy storage. This may well turn out to be more difficult than and just as capital-intensive as the devices for absorbing and converting the energy in the first place. The recent controversy in *Nature* concerning the storage requirements associated with a system of windmills indicates the crucial importance of the storage capacity if steady power is to be generated from variable input.

Most domestic solar heating installations to date are intended largely or wholly for water-heating, and the thermal mass of an insulated hot-water tank provides all needful storage capacity. If, however, space-heating is proposed as well, or even electricity generation, then a more sophisticated storage facility is needed. Heat can be stored in pebble beds, water tanks or salt baths and retrieved by forced heat exchange when required. However, space is expensive and a high storage capacity per unit volume (specific capacity) is therefore at a premium. A high specific capacity implies exploitation of chemical reaction energies as distinct from simple specific heats, and it is in this connection that metal hydrides have received a good deal of attention in the past four years.

A number of metal hydrides (TiFe, $LaNi_5$, Mg_2Ni and Mg_2Cu are the most studied) have convenient dissociation pressures and temperatures, substantial heats of dissociation and can store more hydrogen per unit volume than can a liquid-hydrogen Dewar vessel (Hoffman *et al. Int. J. Hydrogen Energy* 1, 133; 1976). A number of laboratories, of which Brookhaven National Laboratory has been the most active, have been examining the metallurgical and engineering features of hydride storage installations, partly with automotive uses in mind. A recent paper from Argonne National Laboratory (Green, Schreiner & Shaft *Int. J. Hydrogen Energy*, 3, 303; 1978) presents a conceptual study of a system using such hydrides for storage of heat and its use in adjustable proportions for domestic heating, air-conditioning and electricity generation. It is a welcome publication, since much work in this field is issued in inaccessible reports or expensive conference proceedings — what might loosely be termed scientific *samizdat*. All 12 references at the end of this paper are to unpublished reports, house journals or conference proceedings, and this practice leaves little scope for the serendipitous browsing that so often generates new scientific ideas. For this reason, the existence of regular journals like the *International Journal of Hydrogen Energy* is particularly welcome; in a field like this, the absence of a highly specialised journal is apt to be associated with entrenched scientific *samizdat*.

The Argonne apparatus, in the simplest of its several forms, involves a solar collector with concentrator that can warm a heat-transfer fluid to 140 °C. The warm fluid then heats up a primary $LaNi_5H_6$ bed, releasing hydrogen at about 50 atm. The released hydrogen is cooled to 50 °C and expanded to a pressure of 40 atm or less. The cool, lower-pressure hydrogen is then converted to hydride in a secondary bed (a cheaper bed using mischmetall, a mixture of rare earth metals, instead of lanthanum, is proposed). The heat released during expansion and hydration is absorbed in a separate loop of heat-transfer fluid, and this heat (at 50 °C) can be used for space-heating. Hydrogen is released from the cooled $MmNi_5H_6$ secondary bed by lowering the pressure to about 8 atm and can be recombined with the primary $LaNi_5$ bed at 50 °C at the same pressure. That bed is then reheated by solar energy and the cycle recommences.

This represents a simple non-storage cycle. In fact, the storage bed would be kept hydrogenated till nightfall and the apparatus would then be operated in heat-pump mode; the primary bed is kept at 50 °C by manipulating heat-transfer fluid and is used as a source of space heat, while the secondary bed can progressively dehydrogenate at low pressure and 0 °C; this low temperature is achieved by absorbing heat from the environment.

To achieve continuity in operation (as would be required for continuous air-cooling or for electricity generation) at least two primary and two secondary beds would be used, with appropriate switching of hydrogen and heat-transfer fluid flows so that each undergoes a staggered cycle: absorption, heating, desorption, cooling. The cycle length is presumably limited by maximum heat-transfer rates at one extreme and by low demand for domestic heat at the other extreme. A variant of this cycle allows the apparatus to be used for air-conditioning instead of space-heating.

A more complex system involving three beds of each kind would permit a proportion of the absorbed solar energy to be used for electricity generation. (Warm hydrogen would be passed through a turbogenerator: the alternative of oxidising the hydrogen to water in a fuel-cell would be inappropriate in a closed cycle system). The authors undertake a detailed assessment of realistic efficiencies to be expected, allowing for heat losses involved in heating and cooling the storage beds: the maximum theoretical efficiency is 28% (electric power as a fraction of solar heat absorbed by the primary bed), the expected realistic efficiency is 16.5%. If the apparatus is used simply as an air-conditioning (cooling) device the heat-pump mode ensures that, at ambient temperature, for each mole of hydrogen about 3.3 times the dissociation energy can be extracted as useful cooling power.

Nothing is said about economics. The high cost of mischmetall and even higher cost of pure lanthanum would seem to place a question-mark against the particular hydrides chosen, in spite of their particularly convenient dissociation temperatures.

The Argonne design prompts a number of reflections. The apparatus would be of very considerable com-

plexity Each bed would be associated with several heat-transfer loops, pumps and pressure valves, and there would need to be an elaborate automatic control installation to switch both hydrogen and heat-transfer fluid into appropriate circuits at appropriate times, to secure the staggered cycles and also in response to changes of incoming solar power level, space-heating or cooling demand, hydride temperature, hydrogen pressure and fluid temperature in various parts of the apparatus This is quite apart from the control provisions needed to keep electric output constant in the face of varying hydrogen temperatures and pressures. There is a widespread illusion that renewable energy sources such as Sun and wind are necessarily associated with primitive or intermediate levels of technology: people are apt to think in terms of solar cookers for use in Indian villages or of water-heaters for swimming-pools or for Israeli dwellings. In fact, if solar power is ever to be more than a negligible fringe energy source, plainly it must be accompanied by very advanced technology This is true both of the initial capital input (such as the manufacture of silicon solar cells) and of the maintenance of complex installations, which will place high demands on initial design (perhaps in the form of replaceable modules), on fault diagnosis and on high reliability in manufacture. Such things will certainly be 'mills' in William Blake's sense, though bright and beneficial rather than dark and satanic

In the very early days of domestic electrical power, a century ago, there was a brief sharp argument as to whether separate electric generators were to be installed in the basement of each home, or central generation and distribution was preferable One may wonder whether, before another century is out, this argument will be reopened in sunny parts of the world. Meanwhile, the most promising application, in the short term, of installations like the Argonne design would be for air-conditioning in hot, isolated and fuel-deficient places like North-western Australia. Such an air-conditioning facility, built into dwellings and communal spaces, may well be the factor that determines whether or not labour can be attracted to work in mines in such inhospitable places ☐

Sickle cell: a metastable disease

from Robin Briehl

SICKLE-cell anaemia was the first 'molecular disease' to be discovered; the term was coined originally for it by Linus Pauling to celebrate the discovery that the condition was linked to the presence of a mutant haemoglobin in the red cells of the patients In the quarter century that has passed efforts have been made, with less than conclusive results, to understand in detail just how the deviant solubility properties of the abnormal haemoglobin bring about the sickling phenomenon, and what, in the light of such a biochemical or biophysical understanding, one could hope to do about it. I want to consider here one aspect of this multifaceted problem

In the classical picture the pathogenesis of sickle cell disease depends on deoxygenation-dependent polymerisation of the abnormal haemoglobin S into long fibres and the formation from these of anisotropic, spindle-shaped, liquid crystalline bodies, designated tactoids. The final result is a viscous 'gel' which deforms the erythrocyte and makes it rigid. Gelation and its inhibition have been studied intensively in the past 5 years by attempts to develop covalent or non-covalent inhibitors of gelation, by elucidation of the structure (see *News and Views* **272**, 476; 1978) of the intermolecular interactions in the fibre, and, the subject of this note, by studies of the kinetics and equilibria of gel formation.

Under the currently accepted model for the kinetics of gelation, a long stage of highly cooperative nucleation is followed by rapid fibre growth and then by a slow alignment of fibres to the anisotropic state[1] The termination of the nucleation or latent stage, originally observed through an increase in viscosity[2] is also manifested in heat absorption, the onset of birefringence[1] turbidity increase[3] and broadening of water proton magnetic resonance linewidths[4]. The activation energy for nucleation is about $90\,\mathrm{kcal\,mol^{-1}}$. During the latent stage the supersaturated solution of haemoglobin monomers (that is, tetramers, molecular weight 64,500) is unstable with respect to the phase of isotropically oriented fibres. The latter, in turn, is unstable with respect to the formation of the anisotropic state, as evidenced by the slow development of birefringence

Minton[5] has applied fundamental models for the entropically driven formation of tactoids from long rod-like molecules or particles to the haemoglobin S system to develop an equilibrium model of gelation. The non-ideality which arises from the large excluded volumes of the highly asymmetric polymers results in a phase diagram containing regions of purely monomeric haemoglobin and of isotropically and anisotropically oriented fibres, the last either in the tactoidal state or in a very highly aligned and concentrated quasi-cystalline condition. The diagram also contains a stem-shaped heterogeneous region reflecting a separation into conjugate isotropic and anisotropic phases.

Pumphrey and Steinhardt[6] have now discovered and characterised a new state of haemoglobin S which defines a new metastability as well If concentrated solutions of deoxyhaemoglobin S are stirred above a low threshold rate, birefringent, uniaxial, needle-like crystals appear instead of the familiar gel Since seeding of a gel with crystals results in conversion to the crystalline state, the crystal form is more stable thermodynamically, although only marginally so, since the well-defined solubility of the crystals in very near the minimal gelling concentration. Our observations[7] on dilute gels of deoxyhaemoglobin S, observed in 1.7 M phosphate, show a similar metastability: As a function of rates of warming and shaking, there is reversible formation of either a gel or a fluid but more turbid suspension.

In addition, polymorphic forms of the fibre exist (see *News and Views, op. cit.*), so that structural as well as physical chemical studies demonstrate

the existence of different condensed states.

The most common assay of gelation, minimal gelling concentration, depends in part on kinetic factors. A better measure of thermodynamic properties is obtained from the recently developed C_{sat} assay in which a preformed gel is sedimented and the concentration of the supernatant, consisting of monomers previously in equilibrium with the condensate, is obtained. C_{sat} is independent of total haemoglobin concentration and is thus a saturating concentration which reflects a phase separation[9–11]. Magdoff-Fairchild *et al.* suggest the possibility of two different condensed phases on the basis of their observation of a sharp change in the apparent van't Hoff enthalpy of gelation at 22 °C. Our studies show that C_{sat} is always markedly greater than the minimal monomer concentration needed to produce measurable aggregation, C_{agg}, and therefore the overall solution to gel equilibrium cannot be treated as a single sharp polymerisation and phase condensation C_{agg} reflects polymerisation free energy, whereas C_{sat}, although also a monomer concentration, reflects the separation into isotropic and tactoidal phases.

The endothermic enthalpy for the entropy driven process of gelation has been measured by Ross *et al.*[12] from the temperature dependences of C_{sat} and birefringence observations, and by direct calorimetry. ΔH falls from +4,000 cal mol^{-1} at 15 °C to 2,200 at 25 °C to zero at 37 °C The large associated ΔC_P is −197 cal degree mol^{-1}. Most of the enthalpy is associated with the polymerisation process, ΔH for alignment being in the neigbourhood of zero. These results are consistent with a polymerisation process dominated by hydrophobic interactions and alignment dependent on entropic forces as modelled by Minton[8]. The results of Magdoff-Fairchild *et al.*[9] show similar ΔH values and also a *p*H dependence of ΔH.

The three important physiological ligands of haemoglobin, oxygen, proton and 2,3 diphosphoglycerate (DPG) affect gelation. Thermodynamic studies (of C_{sat} and C_{agg}) show that protons above *p*H 6 8 favour gelation and that an optimum for gelation exists near *p*H 6.8[10,11,13] Protons also shorten the latent stage delay time[14] In our studies DPG, and more so inositol hexaphosphate, also favour gel formation On the other hand, under a single set of conditions resembling those in the erythrocyte, Swerdlow *et al*[15] show no effect of DPG on gelation. Kinetic studies show that DPG shortens the delay time[16]. The oxygen equilibria of dilute haemolysates of haemoglobins A and S have long been known to be indistinguishable even though haemoglobin S cells have a lower oxygen affinity than normal cells. Gill *et al.*[17] have now examined concentrated haemolysates and found that a concentration-dependent lowering of affinity exists for haemoglobin S at low saturations, associated with evidence of polymerisation by light scattering, but not at high saturations. The effect depends on the free energy change associated with polymerisation of the deoxygenated form.

In an extension of previous thermodynamic analyses, Minton[18] and Ross and Minton[19] have shown that the non-ideality arising from the excluded volume of monomeric haemoglobin in solution makes a very large contribution to thermodynamic activity at the high haemoglobin concentrations required for gelation The non-ideality as obtained from osmotic pressure data and the sedimentation equilibrium results of Williams[20] and Briehl and Ewert[13] can be well accounted for under a model in which the haemoglobin molecule in solution is treated simply as a hard, impenetrable, quasi-spherical particle. Ross *et al.* demonstrate that this non-ideality suffices to explain the effects of some non-S haemoglobins on gelation in mixtures with haemoglobin S; no direct interactions of copolymerisation are required. The non-ideality thus explains the previously observed nonspecific facilitation of gelation of haemoglobin S by the addition of haemoglobin A or F or ovalbumin[21,22] and receives further confirmation from the demonstration that isolated α and β subunits have the same effect on gelation of haemoglobins S as haemoglobin A[23]

Ice-Age palaeo-oceanography of the Mediterranean

from N. J. Shackleton

THE CLIMAP project had as its first major goal the reconstruction of global climate at the peak of the last glaciation about 18,000 years ago. One purpose of this was pure geological excitement, another was to use the resulting reconstruction as a boundary condition for numerical general circulation models of the atmosphere (for example, Gates *Science* **191**, 1138; 1976). One of the most exciting moments in the CLIMAP project was the day we first compared the climate simulated by Gates' model for the ice age world, based on oceanographic data, with independent geological observations from the continents.

On the coarse grid-scale with which CLIMAP was forced to work the Mediterranean Sea looked rather insignificant, particularly considering the vast areas of Pacific we had to deal with, and it was at first treated rather summarily. However, it is an area of special interest to other workers, and Thiede has now presented a CLIMAP reconstruction of the Mediterranean alone (page 680 of this issue of *Nature*). The reconstruction is based on the Foraminifera. and its strength lies in the fact that it was possible to obtain a temperature calibration of the planktonic foraminiferal faunas of the Mediterranean utilising sediment samples from the North Atlantic and particularly from the Bay of Biscay This is important because the glacial faunas clearly include some that do not lie in the present range within the Mediterranean.

Glacial winter sea surface temperatures ranged from below 7 °C on the entire Spanish and French coasts to more than 19 °C on the Egyptian coast, while summer temperatures were below 13 °C along the Spanish and French coasts, rising to over 25 °C in the South-East. Thus the Western Mediterranean appears to have been very considerably cooler than it is today, although in the South-Eastern corner conditions were not greatly different from today.

This reconstruction will be received with great interest by archaeologists who are exploring man's existence around the Mediterranean during the last glaciation There is not nearly as much information as one might like preserved in some of the caves occupied around the Mediterranean for reconstructing the past environment, and a reconstruction of sea surface temperatures should provide a welcome input. One hopes that a synthesis will emerge which utilises the marine and terrestrial evidence together; at the least, it should be possible to calibrate Thiede's estimate of the seasonal temperature range by making oxygen isotopic measurements in some of the mollusc shells which prehistoric man so thoughtfully collected for our use.

N. J. Shackleton is at the Sub-Department of Quaternary Research, University of Cambridge.

0028-0836/78/0276—0667$01.00

Behe and Englander[24] have extended this approach by examining the effects of various non-haemoglobin S proteins on the kinetics of gelation. They show that the delay time in the nucleation stage, formally dependent on approximately the 30th power of haemoglobin S concentration[25], is about 10th order in activity. They conclude that the size of the critical nucleus, previously considered equal to the formal order of the reaction, is composed of between 10 and 18 monomers.

Pathogenesis

Eaton *et al.*[26] and Sunshine *et al.*[27] have already proposed convincingly that the delay time in the nucleation stage, dependent on a high power of the supersaturation ratio (defined as the ratio of total haemoglobin concentration to C_{sat}), can be a major factor in the clinical development or inhibition of sickle cell crises. Presented with metastable behaviour at a number of stages, at least three phases, isotropic, tactoidal and crystalline, containing highly polymerised or condensed haemoglobin, and evidence of microscopic fibre polymorphism, we may now ask whether kinetic factors at other stages of gelation might not govern pathogenesis by facilitating formation of one or another phase and/or by bypassing the most pathogenic phase. Given this polymorphism, we also need to reconsider the classical view that the sickled erythrocyte is a membrane covered tactoid. Such an approach is implied in Minton's analysis of the phase structure of the gel and suggested also by Hermans[28] observation that the formation of tactoids in rod-like poly-γ-benzyl-L-glutamate is accompanied by a sharp decrease in viscosity. Harris and Bensusan have observed that haemoglobin S viscosity, reaching a maximum after the nucleation stage, later falls to a lower level. Since this fall apparently occurs in the period of increasing birefringence, tactoid formation here may also be associated with diminished viscosity.

Under this approach, sickle cell disease can be viewed as a disease encompassing multiple phases and phase changes. Clinical variability among different patients and the episodic nature of the disease may depend on kinetic paths and on marginal changes in free energy. Accordingly, control of these factors in the natural history of the disease may be at least as fruitful an aproach to specific treatment as the development of a covalent or even noncovalent inhibitor of gelation. In fact, as pointed out by Behe and Englander, modified haemoglobin molecules which do not copolymerise still exert a highly deleterious effect due to the large excluded volume effect.

If these many major advances permit this first described molecular disease to be seen as a disease of physical chemistry, then this view can be considered to have its origin in the work of Allison[29] which anticipated many of the modern developments. ☐

Laser annealing of semiconductors

from D. Weaire and J. I. B. Wilson

In recent years the laser has become the magic wand of the physicist and chemist, facilitating spectroscopic analysis, inducing chemical reactions, separating isotopes. Laser annealing of semiconductors is emerging as yet another exciting new application.

Annealing is the healing process by which a crystalline semiconductor, imperfectly grown or damaged in the course of introducing dopant atoms, is restored to a state of comparative crystalline perfection. This is usually achieved by holding the sample at 800–1,000 °C for 30-60 min (thermal annealing). It now seems that illumination with a laser beam can in many cases produce better results in one millionth of a second!

Credit for this discovery is generally attributed to various Russian groups who published a series of papers on laser annealing in 1975-77 (see for example, Khaibullin *et al. Sov. Phys. Semicond.* **11**, 190; 1977). In due course interest was aroused in American laboratories and there has been an avalanche of *Applied Physics Letters* on the subject during the present year.

For example, a group at Oak Ridge National Laboratory has studied the annealing of surface layers of silicon implanted with 35 KeV B^+ ions. Other American groups have examined the annealing of As^+ and Sb^+ ion implants of higher energy (100 and 150 keV) in Si, and implanted GaAs. Ion implantation is a particularly disruptive doping process in which ions are accelerated to energies sufficient to displace the host atoms from their regular lattice positions. By this means shallow, heavily doped layers are produced, but many dopant ions are left on undesirable inactive sites and a great deal of structural damage is produced. Thermal annealing repairs much of this but only laser annealing is effective in removing dislocations and stacking faults. In addition, laser annealing is more efficient in rendering implanted ions electrically active, even to levels above the normal equilibrium solid solubility limit of the dopant in the semiconductor.

Shallow p-n junctions produced by ion implantation are of particular interest for solar cells. In this case the damage due to ion implantation is responsible for a shorter minority carrier lifetime in the surface layer and hence lower efficiency, when compared with conventional diffused p-n junction cells.

Laser annealing can produce cells at least equal to conventional cells in performance, with a significant overall saving in the energy consumed during production.

It has also been shown that good ohmic contacts, difficult to produce on GaAs without decomposing the compound, can be made on GaAs wafers and epitaxial layers by laser alloying of deposited metal coatings.

Work in the USA at Bell Laboratories and Western Electric, and in Italy at the universities of Rome and Catania has demonstrated the potential of laser annealing for the recrystallisation of both polycrystalline and amorphous silicon. Amorphous Si films produced by evaporation and by implanting Si^+ ions have been recrystallised by single 50 ns ruby laser pulses. Polycrystalline Si has a recrystallisation threshold of $\sim 70\,\mathrm{MW\,cm^{-2}}$, whereas amorphous silicon requires only $45\,\mathrm{MW\,cm^{-2}}$. This is probably due to the difference in their absorption coefficients.

Any one of a variety of lasers can be used, provided that the semiconductor absorption coefficient is sufficiently high at the laser wavelength. Annealing or recrystallisation is generally limited to a 0.5 μm thick surface layer, and this means that there is no undesirable heating of lower layers which might cause unwanted impurity diffusion. Only the highest laser power levels may alter ion implanted dopant profiles, damage the surface of the semiconductor, or produce thermal stress cracks.

Such intense interest at the applied level should surely spawn more basic studies, but this does not yet seem to have happened. For example, at the recent 14th International Conference on the Physics of Semiconductors*, there was little mention of the topic, despite 'Laser Interactions with Semiconductors' as one of the themes. One obvious but difficult fundamental question which is raised by laser annealing is the following. Is it merely a thermal effect, that is, are its beneficial effects entirely attributable to brief localised heating, perhaps including melting? Alternatively, is charge carrier excitation by the ionising radiation a significant factor? Since somewhat similar results have been achieved with elec-

*Held in Edinburgh in September, 1978.

tron beams, and since the extremely high dopant diffusivities observed are compatible with the formation of a molten region, the thermal hypothesis is strongly supported by some experiments. On the other hand, X rays have been observed to enhance the diffusion of metal contacts into the surface of semiconductors and photoionisation may enable charged interstitial impurities to move more easily to vacancies in the crystal lattice. Certainly melting is not essential for removal of ion implantation damage.

This kind of debate has already been conducted in a closely related area. The use of a laser beam to recrystallise locally a chalcogenide glass (a multicomponent amorphous semiconductor such as sputtered Ge–Te–As) was proposed several years ago as an optical storage technique. Even in this case, the relative role of thermal and photostructural effects remains obscure. □

Damn the dogma

from John C. Allen

A TOURIST hotel set in the mountains 350 km North of Oslo was the venue for a recent meeting on Chalones*, a most controversial subject in cell biology. The original hypothesis, which, alas, has been elevated to the status of a dogma, proposed that tissue homeostasis is maintained by mitotic inhibitors termed chalones, which are non-cytotoxic, tissue specific and species nonspecific, and which are secreted by the tissue over which they exert their effect. The theory has been beset by problems ever since its formulation by Bullough and Laurence in 1960, not the least being that in 18 years of intensive research there has been no confirmed report of the isolation of a pure chalone, much less any firm molecular identification. Nevertheless, the scientific importance and potential clinical uses of such substances are manifold, and the literature abounds with reports of partially purified epidermal, granulocytic and lymphocytic chalones. Certainly, the concept has stimulated an immense amount of research, and it was fitting that the participants at the meeting demonstrated their debt to William Bullough (Birkbeck College, London) by presenting him with a portrait to mark his forthcoming retirement.

The organisers had invited two eminent 'devil's advocates' from more respectable realms. A. B. Pardee (Sidney Farber Cancer Institute, Boston) and R. W. Holley (Salk Institute, San Diego) fulfilled this difficult role admirably and with unanimity. In their summing up, Pardee believed that there was no evidence for the existence of chalones as defined by Bullough, and Holley exhorted all to stop concerning themselves with restrictive definitions with the memorable phrase 'damn the dogma'. However, both felt that endogenous inhibitors do exist and that workers should now set about purifying them from associated nonspecific activity.

Indeed there was no shortage of inhibitors: over 30 were described, with molecular weights ranging from 100,000 to 300! Doubtless, several will prove to be identical, and many trivial. Among the more interesting is that painstakingly isolated from blood by W. R. Paukovits (Cancer Research Institute, University of Vienna.) This is an SH-containing pentapeptide of molecular weight 590 which apparently contains a pyroglutamyl N-terminus. It exerts a fine control over granulocyte proliferation but is inert towards thymic lymphocytes. The nearest we have to a pure lymphocyte chalone is the thymus-derived peptide of J. C. Houck (Virginia Mason Research Center, Seattle). This substance, of molecular weight 1400 and purified by final cellulose chromatography, inhibits lymphoblast formation by 50% in mixed lymphocyte culture at only 1 μg ml^{-1}. Houck informally revealed that sequencing is well under way. It can only be hoped that his characteristic optimism will this time be justified, and that a homogeneous preparation is in the offing.

Problems associated with isolation received thorough discussion. G. Isaksson-Forsen (University of Oslo) and A. Quirk (University of Newcastle) independently reported aggregation with concomitant loss of activity during purification of epidermal inhibitors. Other explanations for chalones' elusiveness were suggested, including their secretion as zymogens and their tendency to adhere to larger molecules. However, there is little firm evidence, and such effects may turn out to be 'laboratory specific'.

Unfortunately, much work reported was on impure and even crude tissue extracts. Surely, the dangers of spurious effects from artefacts should be appreciated by now? J. C. Allen (North E. Wales Institute) described work with synchronised lymphoma cells which showed how the simple molecule spermine could exert a very specific inhibitory effect. H. R. Maurer (Freie Universität, Berlin) warned of the dangers of reliance on the measurement of tritiated thymidine as sole indicator of cell proliferation, and advocated colony counting in preference. It was agreed that no single assay is satisfactory; perhaps the best plan is to adopt a simple *in vitro* screening procedure and to substantiate the results with a series of assays which must include an *in vivo* test.

Recent studies on epidermal inhibitors have provided some intriguing pointers to their true specificity and perhaps to *in vivo* function. A. Thornley (Witwatersrand University) has discovered that his epidermal chalone has an inhibitory effect not only on epidermis, but also on other specifically epithelial tissues including lung, trachea and bladder. This substance may thus be cell line, rather than tissue specific. In addition, S. Bertsch (German Cancer Research Centre, Heidelberg) has partially purified an inhibitor from a keratinised epithelial tumour of the bladder. This was active only on keratinised, and hence differentiated epithelial cells. This is evidence, albeit insubstantial, that the inhibitor was acting to maintain differentiation rather than as a cell cycle modulator.

Thus many workers have already subconsciously rejected the 'dogma' and have adopted a simple operational definition of the useful word 'chalone'. Perhaps the most encouraging aspect of the meeting was the healthy self-criticism. There is now only one reason why chalone research should not move into the mainstream of cell biology, and that is the lack of a homogeneous preparation. This sense of frustration is understandable, but the cell biologists will have to be patient and give the biochemists time to catch up. □

*An International Symposium on Chalones in Normal and Malignant Cell Populations was held at Geilo, Norway on 29 October–2 November. It was sponsored by the Norwegian Cancer Society and was convened by Professor O. H. Iverson (Institute of Pathology, University of Oslo).

Status of biocontrol in medical entomology

OVER the past two decades, there have been major and continuing advances towards practical biological control of arthropod vectors of disease. Until the late 1950s, biocontrol in medical entomology meant little more than the (sometimes ecologically irresponsible) use of larvivorous fish—primarily *Gambusia affinis* subspp. Since then, though, the growing number of investigators in this field have increasingly concentrated upon the feasibility of control by mass-produced microorganisms and parasites.

0028–0836/78/0276—0669$01.00

The current status of biocontrol of vectors is nowhere better exemplified than by its place in the World Health Organization's Special Programme for Research and Training in Tropical Diseases (TDR). This aspect of the Special Programme is emphasising innovative approaches to the control of the major vector-borne diseases of developing countries. Little more than a century ago, most of these diseases were still rife in today's industrialised countries, in some of which certain such causes of widespread morbidity and mortality (malaria in the southern United States, for example) persisted in significant foci until after World War II. During 1978, some 20 research contracts were granted under TDR's biocontrol component. About 30 will be implemented during 1979, notably in West Africa.

Hitherto, vectors of malaria, the filariases, and trypanosomiases, and arboviral diseases (likewise the snail hosts of schistosomiasis) have been attacked almost exclusively by the application of toxic chemicals. These, particularly the persistent synthetic organics, have lost popularity for various reasons including political ones. Undeniably, when over-applied, they can have damaging effects on health and environment. Moreover, genetically based resistance to them seems inevitable. Therefore, the prospects for practical biocontrol of vectors (within the broader concept of ecologically soundly based integrated control) have secured wide interest.

Applied invertebrate pathology is the aspect of biocontrol of vectors that has developed most strikingly in the past 20 years. In consequence, certain bacteria, fungi, protozoa and nematodes can now be seriously considered for widespread use against medically important arthropods. The status of this field was discussed at a recent meeting*. Two groups of microorganisms already showing promise in agricultural and forestry entomology were not dealt with—entomopathogenic viruses because not is yet ready for commercialisation in public health entomology, and protozoa because the results of a 1977 Round Table on their potential for biocontrol are about to be published in a post-congress volume from the 5th International Congress of Protozoology (New York) Relevant examples from the other major taxa follow.

Possible agents

Laboratory and field testing of the efficacy of *Bacillus thuringiensis* var. *israelensis* and *B.sphaericus* (notably strain 1593) has demonstrated high pathogenicity to larval mosquitoes, including in the case of the latter species, anophelines in Nicaragua WHO/TDR supported the work there, and is arranging for designation of a strain of *B.t.israelensis* which will shortly be tested against *Simulium damnosum* in West Africa following very encouraging tests of this bacterium against larval blackflies in Newfoundland. Both bacteria are mass-producible by available technology. So far, neither has been shown to pose health or environmental hazards, questions to be further investigated as standardised powder preparations are considered for commercial production.

Some of the fungi eligible for evaluation for vector control (for example, *Culicinomyces* of mosquitoes, *Simuliomyces* of blackflies and *Pseudocoelomomyces* of tabanids) were only recently discovered. This suggests that greater attention to this topic will inevitably reveal yet unknown fungal (and of course other) candidates. Those already under consideration range from specialised aquatics (including mosquito pathogens of the genera *Coelomomyces*, *Lagenidium* and *Leptolegnia*) through Entomophthorales (including *Entomophthora culicis* and two organisms lately described from the USSR, *Pseudocoelomomyces milkoi* and *Simuliomyces lairdi*), to Fungi Imperfecti. A representative of the latter, *Metarhizium anisopliae*, has already been tested with promising results against mosquitoes, including anophelines, in Nigeria. Similarly promising tests have been undertaken with *Culicinomyces* against larval mosquitoes in Australia.

Trials have also been carried out from the tropical South Pacific to North America and the USSR, with species of *Coelomomyces* (none of which can yet be mass-produced except *in vivo*, using laboratory colonies of mosquitoes), *Lagenidium* and *Leptolegnia* Certain of the fungi under assessment, notably *M. anisopliae* (long since cultured in large quantities and widely applied in the USSR), can also be mass-produced on simple media. This is of obvious interest to nations with restricted access to hard currencies.

Various nematode worms, primarily Mermithidae, have been identified and studied from all major vector groups To date, however, only one species—the warm-water mosquito mermithid, *Romanomermis culicivorax*—is approaching commercial production (the first registration based on it having been issued in the USA in 1976). Mermithids can be applied in the field by equipment developed for chemical pesticides, from pressurised hand-sprayers to helicopter booms. Major field tests so far undertaken have involved the use of as much as 750 kg of cultures against *Anopheles albimanus* in a land-locked lake in El Salvador, with up to 94% reduction of the host Smaller-scale tests in progress under WHO sponsorship have demonstrated the feasibility of practical applications of *R. culicivorax* against container-breeding aedine filariasis and dengue-vectors in the Republic of Western Samoa and the Tokelau Islands, South Pacific.

Commercial prospects

Turning now to imminent commercial prospects, there are two main industrial interests The first is in spore-forming bacteria, exemplified for present purposes by *Bacillus thuringiensis* var. *israelensis*, and *B. sphaericus*. Further moves in this connection will of course be much influenced by the history of lengthy investment and successful commercial production of *'B.t.'* products against agricultural and forestry pests. The second interest concerns *Romanomermis culicivorax*, in which two American companies have already shown interest.

One of these firms has stopped all research and product development work on a mermithid product for financial reasons. The second, Nutrilite Products, Inc. (NPI) is commencing its second year of work aimed at commercial development and sales.

Two major problems that still demand a solution are the design of a shipping container that will protect the mermithid eggs during storage and shipment, and elimination of fungus contamination of the cultures. A 2 year $30,000 WHO/TDR grant has just been awarded to NPI to continue work along these lines. Even if these problems are solved there is some risk that demand for this biological may not be great enough to sustain a profitable business venture. Additional market research will be needed in this area.

In sum—granted necessary encouragement, biocontrol procedures for use against arthropods of medical and veterinary importance could become a significant element in integrated methodologies for vector control in the very near future. However, they must become so, for obvious reasons of environmental unacceptibility of, and inevitable resistance to the synthetic organic pesticides. The only real problem to be faced, therefore, is that of adequate support—at a major level, and now ☐

Clutch size in plants

from Robert M. May

THE idea that animals will tend to have smaller litters or clutch sizes in the tropics than in temperate regions has been around for some time. The underlying thinking is that environments tend to be more predictable and biological interactions to be relatively more important in the tropics (so that an evolutionary premium is placed on investing in the care of young), whereas temperate environments are relatively less predictable (so that the evolutionary pressures are to buy as many tickets as possible in what is necessarily a chancy lottery). These notions are developed more fully in, for example *Nature* **257**, 737; 1975; **267**, 394; 1977.

Much data on clutch and litter sizes of birds and mammals supports this view. Lack put together information on birds which (as summarised by Southwood *et al. Am. Nat.* **108**, 791; 1974) shows 82 species that inhabit tropical forests to have an average clutch size of 2.3, 260 species from tropical savannas to have an average of 2.7, 21 species from tropical arid areas to have 3.9—an overall average clutch size of 2.7 for 363 tropical species; in contrast, 88 species from middle Europe have clutch sizes averaging 5.6. In a related but more detailed study, Cody (*Evolution* **20**, 174; 1966) took more than 200 species of birds in the families Tyrannidae, Icteridae, Anatidae, Thraupidae-plus-Parulidae and Troglodytidae, and graphed the linear regression of clutch size against latitude for each family. The regression lines all have a roughly similar slope, corresponding to the mean clutch size increasing from around two to around five or six as one goes from the equator to 50° north or south latitude. A similar regression analysis of litter size as a function of latitude for North American mammals gives more varied results (Lord *Am Midl. Nat* **64**, 488; 1960). This work is most easily summarised by christening the slope of the regression line to be s; s then measures the increase in mean clutch size per 1° increase in latitude (Cody's results correspond to s around 0.06, with a range from 0.03 to 0.09). Lord finds statistically significant patterns of increase in litter size with latitude for 21 species of rabbits ($s=0.25$), 16 species of tree squirrels ($s=0.05$), 18 species of meadow voles ($s=0.13$), 7 species of chipmunks ($s=0.05$), 14 species of deer mice ($s=0.16$) and 12 species of shrew ($s=0.12$). Ground squirrels, pocket gophers and rats show increases that are not statistically significant, while foxes, cats, and mustelids show no apparent correlation between litter size and latitude. Tinkle, Wilbur and Tilley (*Evolution* **25**, 55; 1970) have compiled data for lizards, which show 28 tropical species having an average clutch size of 5.5 while 57 temperate species have 6.1; although in the expected direction, this difference is not statistically significant.

The broad evolutionary arguments that underline these studies of animal reproduction apply equally to plants, and it is interesting to ask whether given groups of plants manifest systematic trends in 'clutch size' as a function of latitude. Levin and Turner have recently undertaken such a study, arguing that "the number of ovules per flower (or per head in the Compositae) may be referred to as clutch size in plants, in that the development of a seed cluster from these ovules represents a discrete reproductive episode and energy commitment in time and space". (Appropriately enough, their paper is in a book commemorating David Lack: *Evolutionary Ecology*, (eds. Perrin and Stonehouse) Blackwell, 1977). One obvious problem here lies in deciding how to define 'clutch size' for plants. Levin and Turner's choice has the incidental advantage that the number of ovules per flower is relatively constant for a given species, often indeed being used by systematists as a diagnostic character. However, the net reproductive strategy for a plant also involves the total number of flowers and thence seeds, along with many other factors, which complicates any comparison with animals. Levin and Turner acknowledge this caveat, but feel their definition of plant clutch size makes for an analogy that is worth pursuing.

Levin and Turner explore the clutch size relationship within the tribe Heliantheae, which is a New World tribe of the widespread family Compositae. Their study encompasses 1,007 species from the material at the herbarium at the University of Texas at Austin. The clutch size among these species spans a wide range, from 1 in the genera *Clibadium*, *Lagascea* and *Icthyothere* to as much as 500 in other genera.

The plants are classified according to their geography (tropics, temperate, alpine) and growth form (annual herb, perennial herb, woody shrub). The average clutch size in each category is as tabulated, with the sample size in parentheses. There are consistent patterns for the herbaceous plants, and, as expected, clutch size increases with latitude. The alpine shrubs are discrepant with the general pattern; Levin and Turner offer no explanation, but it is conceivably because this growth form is under severe stress at alpine latitudes.

Growth form	Region			Form mean
	Tropics	Temperate	Alpine	
Annual herb	39(163)	62(106)	110 (1)	49
Perennial herb	61(251)	99(161)	104(34)	78
Woody	50(249)	69 (33)	45(11)	52
Region mean	52	83	90	63

Mean clutch size as a function of geographical region and growth form, for plant species in the family Compositae. The sample sizes are given in parentheses.

As each ovule may develop into a seed after being fertilised, it is also interesting to look at the weight for single seeds and the total weight of seeds per head. Levin and Turner show that the expected negative correlation between clutch size and seed weight does exist, but that it is rather fuzzy. More significant is the total head weight, obtained by multiplying the mean clutch size by the mean seed weight. This quantity, which measures the amount of energy invested per head, averages out at 560 mg for shrubs, 350 mg for perennial herbs, and 90 mg for annual herbs. Grouping the species according to geography rather than growth form, Levin and Turner find an average head weight of 300 mg for tropical species compared with 400 mg for temperate ones. This latter result is statistically significant, and accords with our preconceptions.

As emphasised above, clutch size is only part of the overall reproductive picture, which for plants must also include seed weight, total number of seeds, dispersal mechanisms and patterns, and so on. The interplay between reproductive strategies and the shapes and sizes of seeds is discussed by Harper, Lovell and Moore (*Ann. Rev. Ecol. Syst.* **1**, 327; 1970) in a masterly review that defies any glib summary. Levin and Turner survey estimates of the fraction of a plant's annual energy budget that is allocated to reproduction, and suggest for the Compositae the figure is roughly 25%

Robert M. May is Class of 1877 Professor of Zoology at Princeton University.

0028-0836/78/0276—0671$01.00

for annual herbs, 15% for perennial herbs, and probably less than 10% for woody composites. They conclude "these general patterns suggest that, small clutch size not withstanding, annual species of the Heliantheae will have, on average, larger reproductive efforts than perennial herbs. Small clutch size in shrubs will be associated with relatively small reproductive risks in time."

In short, Levin and Turner's study demonstrates 'clutch size' differences that are related to geography and growth form. The authors argue that "there is no reason to assume the patterns observed in the Heliantheae are unique to that tribe or the Compositae as a whole", and I echo their hope that their analysis will spark similar analyses of other plant groups. ☐

Synchrotron radiation at York

from G. V. Marr and I. H. Munro

SEVEN hundred delegates, over two thirds of whom were from outside the UK assembled for the fourth general conference of the European Physical Society.* In this, its tenth year of existence, the EPS took for its theme 'Trends in Physics' and 'Synchrotron Radiation' was one of the eight parallel symposia which formed the basis for a revealing insight into the varied interests of the EPS.

Synchrotron radiation and its applications was introduced and reviewed by S. P. Kapitza (Institute for Physical Problems, Academy of Science, Moscow). This general introduction to synchrotron radiation research was followed by papers on general properties and instrumentation, atoms and molecules, photoemission from solid surfaces using synchrotron and ultraviolet sources, X-ray scattering, X-ray imaging and structural studies.

For the duration of the conference, a large exhibition had been assembled by the Daresbury Laboratory of the UK Science Research Council to describe the nature, generation and exploitation of synchrotron radiation. In addition to providing information concerning the new synchrotron radiation source under construction at Daresbury contributions of material were provided from a number of European laboratories at which facilities are available for synchrotron radiation research. Representatives were present from the laboratories at Bonn and Braunschweig (West Germany), Daresbury (UK), Frascati (Italy), Hamburg (West Germany) and Orsay (France). In addition, the conference was also attended by a group of scientists from laboratories in Moscow, Novosibirsk and Yerevan in the USSR. This group visited the UK under the auspices of the USSR Commission on Synchrotron Radiation with whom in 1977 the UK Science Research Council drew up an agreement for the exchange of information and the holding of joint seminars on synchrotron radiation research.

Reviews and reports were presented at the conference on the following topics. the use of X-ray synchrotron radiation for structural resarch in biology; recent advances in the dynamics of photoselected excited states of molecules and ions; photoemission from solids with synchrotron radiation; elastic scattering and structural applications; synchrotron radiation and X-ray crystallography; X-ray imaging, lithography, microscopy and topography; EXAFS and its use in the study of glass; atomic physics. During the meeting the contributed papers and poster contributions led to discussions of problems associated with the development of new synchrotron radiation sources and of X-ray monochromators; on the soft X-ray and VUV spectroscopy of atoms and molecules, on surface and solid state studies, on the dynamics of protein molecules, on phase transitions in biological systems, the study of clay gels, recrystallisation and grain growth, and the structural studies of powdered materials. Techniques were discussed giving rapid recording of data from these very intense X-ray sources which could be used to yield structure refinement with rapidly changing sample environment.

An unusual feature—for a physics conference—was the evident importance of synchrotron radiation research in biology and in biochemistry This was clearly demonstrated in the use of high resolution X-ray absorption spectroscopy (EXAFS) to elucidate the structure of, for example, polynuclear copper compounds which do not crystallise and of other complex metal containing proteins. Results were given on time resolved X-ray diffraction studies in the millisecond domain for muscle and on high resolution X-ray diffraction data on protein crystals, for example, tyrosyl-tRNA synthetase single crystals. Synchrotron radiation sources are intensely modulated over a wide frequency range enabling the mobility of protein molecules to be observed Using the technique of time resolved fluorescence polarisation spectroscopy in the ultraviolet region a number of proteins were shown to have widely differing degrees of rotational freedom of a single amino acid residue (trytophan). The measured amplitudes and states of these motions suggested that elementary steps of functionally significant conformational changes take place in the subnanosecond time range.

The meeting revealed to the physics community at large that synchrotron radiation sources have a major contribution to make in an astonishingly wide variety of techniques and fields of scientific endeavour. Contributions indicated that developments such as undulators and the free electron laser will become increasingly important during the next decade Indeed it is likely that future synchrotron radiation sources will be considerably different from the present generation where the radiated electromagnetic waves are the result of simple centripetal acceleration of high energy electrons confined to move on a circular orbit by a large iron core dipole magnet. The introduction of periodic magnetic structures within a straight section between conventional dipole magnets in a storage ring can result in very different forms of the emitted soft X-ray spectrum. When the vertical magnetic field alternates in direction up and down along the length of the beam orbit traversed by the electron, the oscillating electron emits a sharply peaked electromagnetic radiation spectrum This peak occurs at a wavelength related to the product of the periodicity of the field with the square of the rest mass energy of the electron and has a width which depends inversely on the number of periods in the undulator. Increases in photon flux of up to one hundred times over that of the normal synchrotron radiation spectrum are predicted for undulator peaks in the soft X-ray region. Results reported at the conference provided details of the spectral features, angular distributions of undulating radiation and polarisation which are in basic agreement with theory, demonstrating that with further development these devices can play a significant part in the next generation of synchrotron sources.

The Synchrotron Radiation Committee of the European Science Foundation, held a two-day workshop during the EPS Conference on the specification and design of a proposed new European Synchrotron Radiation Source. This will form part of a feasibility study to be considered by the European Science Foundation late in 1979 and undulators will represent a significant part of this proposal. ☐

review article

Ogston and the development of prochirality theory

Ronald Bentley

Department of Biological Sciences, University of Pittsburgh, Pittsburgh, Pennsylvania 15260

Ogston's explanation for differentiation of identical groups in symmetrical compounds led to the important stereochemical concept of prochirality, which in turn, has made significant contributions to the understanding of enzyme reaction mechanisms.

IN 1948, Ogston postulated[1], contrary to opinions then prevailing[2], that identical groups in symmetrical compounds such as citrate and aminomalonate could be distinguished, one from another, in enzymatic reactions. He suggested a "three-point attachment" of a symmetrical substrate, $Ca'a''bc$ (the identical a groups are distinguished by different symbols only to facilitate discussion), to three binding sites, A', A'', B (which bind, respectively, a groups and the b group) on an enzyme surface. The arrangement shown for 1 (Fig. 1) is the only way in which binding can be accomplished (assuming further that binding of substrate from below the enzyme surface is not possible). It can be seen, preferably with the help of molecular models, that a' cannot be bound at site A'', with a'' at site A', since to do so requires that c bind at B. If $Ca'a''bc$ had been prepared in a stereo-specific manner so that only one of the a groups (for example, a') contained an isotopic label (●), and if only one of the A sites (for example, A'') was active in some catalytic process, a distinction could be made between the two a groups. As a result of these considerations, Ogston concluded "Asymmetrical occurrence of isotope in a product cannot be taken as conclusive evidence against its arising from a symmetrical precursor."

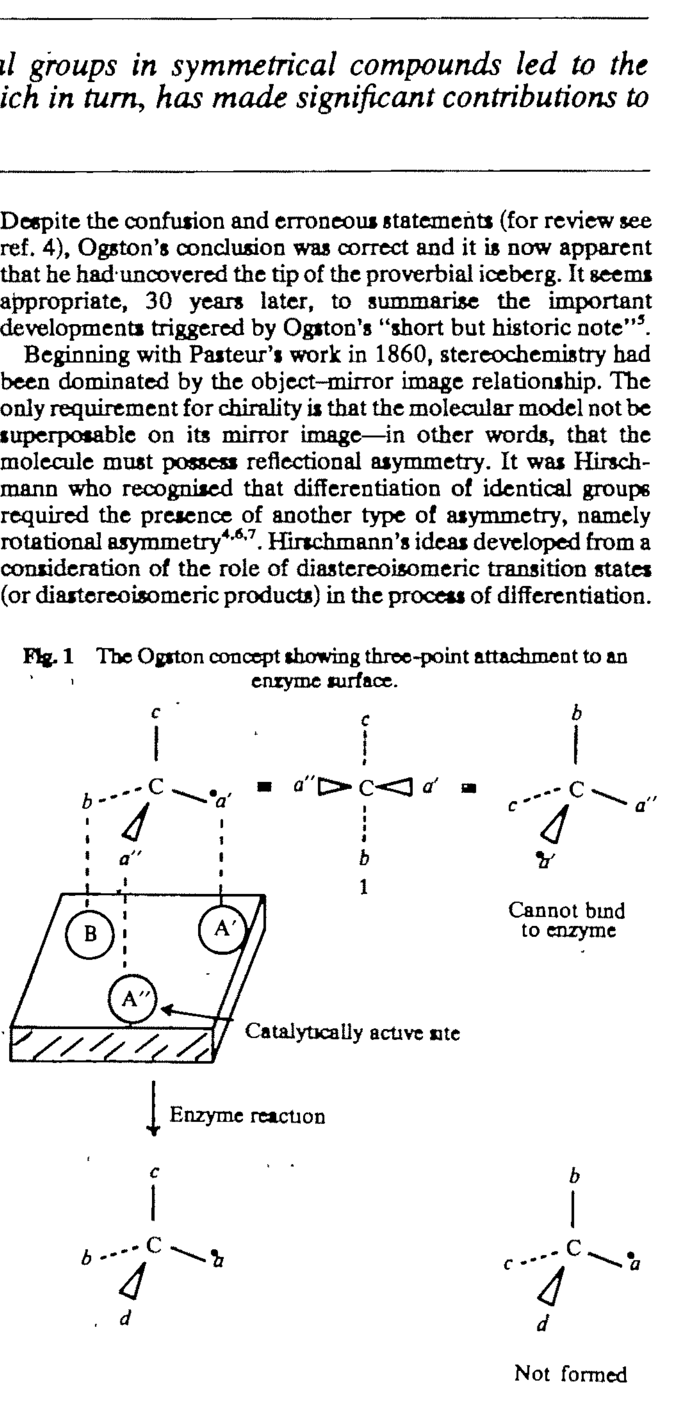
Ogston's letter stimulated lively discussion among biochemists who found it hard to accept that a symmetrical compound could behave in a non-symmetrical fashion. The difficulty people had in understanding this notion was vividly recalled by Vennesland[3]:

> "In a mood of desperation, I sat down with Ogston's paper and took some stick and ball models to assist my thinking. Ogston's paper didn't help, though I read it several times attentively. I thought he was implying a substrate might stay stuck to the enzyme, and that did not help one bit. While I was staring bleakly at the models, they suddenly told me the answer, but not in words, just in a picture. What happened in that moment of sudden insight seemed to be that I was suddenly graced with the ability to see the asymmetric carbon atom as van't Hoff had originally seen it. The feeling I experienced was a curious combination of exhilirating, sweet relief (because there was no contradiction between the two sets of experiments) and total dismay· 'Oh you idiot, why haven't you realised that before'. There were quite a few of us who had experiences similar to mine after the appearance of Ogston's paper. Even though I felt I had grasped the point quite well I found that when I tried to transmit my comprehensions to others it was like the tower of Babel. I distinctly remember hearing myself say 'Of course I know it is symmetrical, but it isn't symmetrical'."

Despite the confusion and erroneous statements (for review see ref. 4), Ogston's conclusion was correct and it is now apparent that he had uncovered the tip of the proverbial iceberg. It seems appropriate, 30 years later, to summarise the important developments triggered by Ogston's "short but historic note"[5].

Beginning with Pasteur's work in 1860, stereochemistry had been dominated by the object–mirror image relationship. The only requirement for chirality is that the molecular model not be superposable on its mirror image—in other words, that the molecule must possess reflectional asymmetry. It was Hirschmann who recognised that differentiation of identical groups required the presence of another type of asymmetry, namely rotational asymmetry[4,6,7]. Hirschmann's ideas developed from a consideration of the role of diastereoisomeric transition states (or diastereoisomeric products) in the process of differentiation.

Fig. 1 The Ogston concept showing three-point attachment to an enzyme surface.



0028-0836/78/0276—0673$01 00

This role had been first recognised by Wilcox[8], and can be explained as follows. Suppose a reagent reacts with $Ca'a''bc$ in a process involving one a group. Two possible transition states (or final products) will exist, one X' for reaction at a', the other X'' for reaction at a''. If the relationship between X' and X'' is enantiomeric, the process produces equal amounts of each since enantiomers have equal stabilities and are formed at the same rate. Hence, in such conditions a' would not be distinguished from a''. If, on the other hand, X' and X'' are diastereoisomers, not in object–mirror image relationship, they are produced in unequal amounts since diastereoisomers have unequal stabilities or are formed at different rates. In these conditions, differentiation of the a groups could occur.

The recognition of the diastereoisomerism as the dominant factor in differentiation, either in the actual formation of a transition state or product, or even in the approach of a reagent, was a crucial step forward. The final proportions of products could depend ultimately either on the probability of successful collisions of reagent with a' or a'' (kinetic control) or on the relative stabilities or solubilities of products (thermodynamic control). Since enzymes contain many centres of chirality the diastereoisomer ratios in a transition state may become very high with almost complete formation of only one of the two possibilities.

Rotational asymmetry

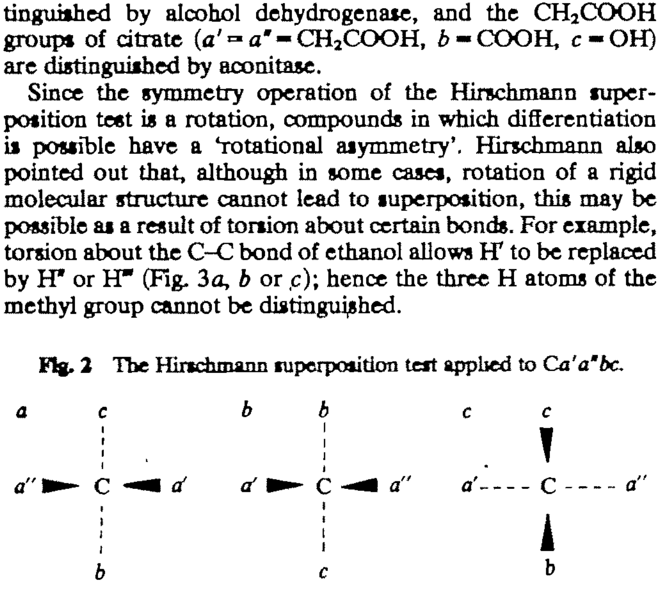
After emphasising the role of the diastereoisomeric intermediates, Hirschmann[6] provided a test to identify those structures in which differentiation of identical groups was possible (at least in principle). The role of diastereoisomeric intermediates required that "the basis for the differentiation of identical groups be sought in some structural characteristic of the substrate". The following "superposition test" was then proposed:

> "A three-dimensional representation of a molecule containing two (or more) identical groups or atoms a designated as a' and a'' is moved so that the position of a'' will coincide with the original position of a'. If this can be done in such a way that the second arrangement is indistinguishable from the first, the groups a' and a'' cannot be differentiated from each other in any reaction. However, if such superposition is impossible, the groups a' and a'' can react with an asymmetric reagent at different rates".

To illustrate the Hirschmann test, I shall consider the two a groups of $Ca'a''bc$. Attempts to rotate the model (Fig. 2a) so as to position a'' on a' lead to the arrangements (Fig. 2b and c). Neither of these rotated arrangements, however, can be superposed completely on the original (Fig. 2a). Hence, a' and a'' in this structure are potentially distinguishable. Many such differentiations have been described in enzymatic reactions (for reviews, see refs 3, 4, 9–14); to quote only two examples, the protons of ethanol ($a' = a'' = H$, $b = CH_3$, $c = OH$) are distinguished by alcohol dehydrogenase, and the CH_2COOH groups of citrate ($a' = a'' = CH_2COOH$, $b = COOH$, $c = OH$) are distinguished by aconitase.

Since the symmetry operation of the Hirschmann superposition test is a rotation, compounds in which differentiation is possible have a 'rotational asymmetry'. Hirschmann also pointed out that, although in some cases, rotation of a rigid molecular structure cannot lead to superposition, this may be possible as a result of torsion about certain bonds. For example, torsion about the C–C bond of ethanol allows H' to be replaced by H" or H‴ (Fig. 3a, b or c); hence the three H atoms of the methyl group cannot be distinguished.

Fig. 2 The Hirschmann superposition test applied to $Ca'a''bc$.



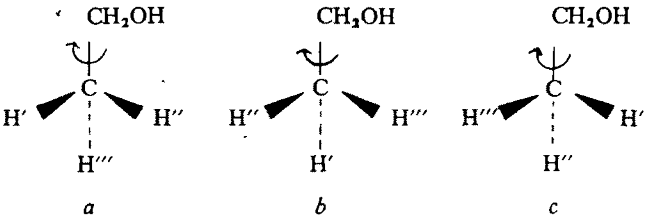


Fig. 3 Equivalence of hydrogen atoms in methyl group.

Provided that a compound has rotational asymmetry, the minimal operation which permits differentiation to occur is that of an approach of a reagent to a molecule which leads to diastereoisomeric situations for approach to a' and a''. Clearly, a "three point combination ... between the symmetrical substrate and the enzyme" is not a mandatory requirement for differentiation; Ogston has noted that his "three-point attachment" hypothesis was not meant to be taken as a literal description of the forces acting between the molecules[15]. Furthermore, identical groups can be differentiated by purely chemical reactions carried out in homogeneous solutions (for example, ref. 16). However, the three point attachment theory caught the imagination of biochemists and to this day is still quoted by some individuals as a requirement for differentiation of identical groups.

The concept of prochirality

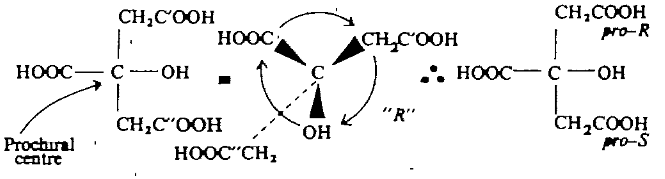
Following Hirschmann's recognition of the nature of rotational asymmetry, it became desirable to have a nomenclature system for each of the two distinguishable groups in $Caabc$. Although Hirschmann[7] had provided one solution, a more convenient system was devised by Hanson[17]. If one of the a groups of $Caabc$ is replaced by an achiral group, d, the product is the chiral compound, $Cabcd$. Since the substitution leads to chirality, Hanson coined the term "prochiral" for the structure $Caabc$. Thus, the central carbon atom of citrate is described as a prochiral centre. Furthermore, Hanson devised a prochirality nomenclature which relates directly to the Cahn–Ingold–Prelog system for specification of chirality. If one of the two identical ligands is considered to be preferred to the other by the sequence rule (without change of priority with respect to other ligands) and if the resultant priority order is R, then the (preferred) ligand is *pro-R* and the other *pro-S*. Prochirality assignment can be illustrated for citrate using the sequence priority and model shown in Fig. 4. However, for a complete description, the original paper or standard works should be consulted[9,10,17]. Although the definition, concepts, and terminology for prochirality proposed by Hanson[17] and elaborated on by Hirschmann and Hanson[18] have come into general use in biochemistry, a somewhat different approach has been advanced by Prelog and Helmchen[19]. Hirschmann and Hanson have argued persuasively for the adoption of their proposals, but clearly an international agreement would be desirable[20].

Structural relationships

An important development has been a detailed examination of the structural relationships between groups and the molecular 'environments' within which they are located. The C-1 hydrogens of ethanol, or the two CH_2COOH groups of citrate are divided by a mirror plane. The environments of these groups at their respective prochiral centres can; therefore, be described as enantiomeric. Other environments may be described in the language of isomerism. The protons at C-3 of L-serine, for example, are not bisected by a mirror plane as is the case for the two protons just considered in ethanol. The proton environments in this case are described as diastereoisomeric. The environmental relationships of the proton at C-2 and either of the protons at C-3 of L-serine would be akin to that between constitutional isomers rather than that between stereoisomers.

Isomers are now divided into three broad groups, constitutional isomers, enantiomers, and diastereoisomers (for reviews, see refs 21 and 22) by asking three questions regarding superposability. The three tests involve (1) comparison by symmetry operations of the first kind—rotation, torsion[18], and for polymers, translation; (2) comparison of bonding (connectivity) graphs (for material on graph theory and studies of isomerism see ref. 22); and (3) comparison by symmetry operations of the second kind involving reflection operations.

Figure 5 represents this series of binary tests in which the question marks signify "Superposition? yes or no", the arrows from the sides of the diamonds, yes (acceptance), and from the bottom, no (rejection). The materially identical compounds are thus compared for superposition by symmetry operations of the first kind, Sy_I (rotation, torsion); by comparison of their bonding graphs vertex by vertex, BG; and by symmetry operations of the second kind, Sy_{II} (operations involving reflection).



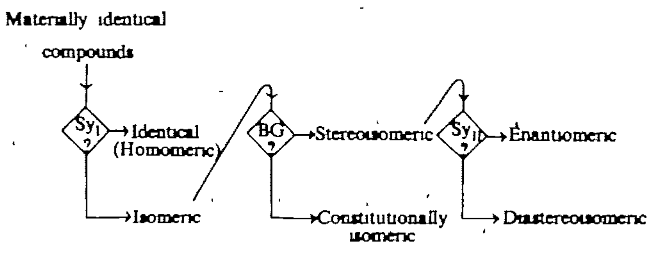
'Modified' priority sequence $OH > COOH > CH_2C'OOH > CH_2C''OOH$

Fig. 4 Prochirality nomenclature for citrate.

Hirschmann and Hanson have used a related scheme ("topic analysis") to describe environmental relationships[18,22] of materially identical groups within a molecule. Groups in identical superposable environments (for example, the three positions of H in CH_3—) are termed homotopic, those in nonsuperposable environments are heterotopic. Heterotopic (but not constitutionally heterotopic) groups are either enantiotopic or diastereotopic; these terms were first used by Mislow and Raban[23]. Enantiotopic groups are those which can be interchanged only by the formal symmetry operation S_n, that is by rotation and reflection; they reside in enantiomeric environments. Enantiotopic groups are commonly encountered in biological systems (examples are the C-1 protons of ethanol and the CH_2COOH groups of citrate). The two products formed by separate substitution of enantiotopic groups, a' and a'', by an achiral group are enantiomers. Hence a chiral reagent is required for differentiation.

Diastereotopic groups (for example, the methylene protons of citrate) are those which have the same constitution, reside in diastereoisomeric environments, and cannot be interchanged by any of the symmetry operations (rotation, reflection, rotation-reflection). There is no mirror plane between them, and if each is substituted separately by an achiral group the two products formed are diastereoisomers (this substitution test with an achiral group readily permits the distinction between enantiotopic and diastereotopic groups). In principle, diastereotopic groups can be differentiated without the intervention of any chiral agent or influence[7,24]. A diagram for topic analysis can be constructed which relates directly to that given earlier for isomer analysis; the same symbols (Sy_I, BG, Sy_{II}) are used in the topic comparisons, the operations now being applied to materially identical groups within the molecule. It should be noted that alternative classifications are being developed; Mislow has outlined a more radical classification based on an isometry on the model of the molecule[25]. As groups may be compared not only within a particular molecular structure (the topic relationships) but also in partial structures, in isolation from any actual molecule[22,25], a further extension of the binary classification system has been proposed. Comparisons of groups in isolation are termed morphic relationships; a sequence of binary congruence tests, which parallels those for isomer and topic classifications, may be easily constructed.

Fig. 5 Comparison of whole molecules—relationships between isomers.



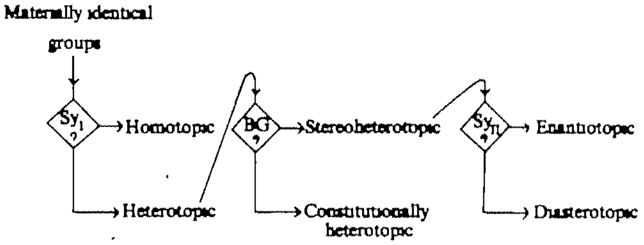


Fig. 6 Comparison of partial structures in intact molecules (or different molecules).

Retrospect and prospect

Could the concept of prochirality have been formulated before Ogston's sudden insight in 1948? Probably not. Those working in biochemistry in the period 1930–1950 tended to have either a chemical or physiological background, and in neither case were they accustomed to think in terms of the symmetry properties of molecules. As Vennesland[3] noted "Actually, anyone considering models, as Ogston obviously did, could easily grasp that compound 1 (that is, citrate with ^{14}C in one primary COOH, ^{13}C in the other) has a mirror image on which it is not superimposable. The reason this had not been grasped was that the wrong answer seemed so totally and obviously right, that no one had felt it was necessary to consult models."

It has now become commonplace to determine actual configurations of labelled compounds which have rotational asymmetry. Reviews and books should be consulted for specific examples[9–14]. One particularly interesting development has been the exploration of chirality in methyl groups containing all three isotopes of hydrogen (for review, see refs 5 and 27).

Although Ogston was primarily concerned to demolish a fallacy in the interpretation of tracer studies of intermediary metabolism, the impact of his thinking has been particularly notable in the consideration of enzyme reaction mechanisms. At a relatively unsophisticated level, the observed stereochemical course of an enzymatic reaction may allow the elimination of a proposed reaction mechanism (for examples see refs 11, 12, 14, 22 and 28). Of considerably greater interest and importance are attempts to develop more comprehensive theories, particularly by comparison of the stereochemistry of analogous enzyme reactions, and by viewing reaction stereochemistry in the context of natural selection. Hanson and Rose have suggested three important principles resulting from the natural selection for catalytic efficiency in enzymes: (1) the use of a minimal number of acidic and basic catalytic groups at the active site; (2) the maximal separation of catalytic groups and/or replacing groups; (3) the use of a minimal motion by the substrate[11,12,14,22,28]. Further research will be needed to test and refine these challenging ideas. However, the debt to Ogston is clear.

I thank Dr B. Vennesland for permission to use the quotations from her article, Drs M. L. Bentley and I. M. Campbell for helpful discussions and Drs K. R. Hanson and H. Hirschmann for suggesting the nomenclature used in the binary diagrams.

A. G. OGSTON COMMENTS—How did I come to make my original discovery? My undergraduate training was in pure chemistry, with a strong preference for physical chemistry, and my first research was on the conductivities of dilute electrolyte solutions in Sir Harold Hartley's laboratory in Balliol. It was my interest in electrochemistry that soon led me (opportunist that I am) into the biochemical field: first with Sir Rudolph Peters, then with E. R. Holiday and J. M. Gulland, to work on the constitutions and electrochemical properties of some biological compounds; then to work (still as a physical chemist) on immune proteins, under E. R. Holiday and J. R. Marrack, at the London Hospital; finally back to Oxford for a second degree course in Physiology and to appointment at my old College (Balliol) as Tutor, mainly teaching Physiology and Biochemistry to medical students.

Some time in 1948, when spending a spare hour looking through journals (mainly with a view to advising my pupils what to read), I came across a paper[1] which seemed to show that aminomalonic acid could not be an intermediate in the conversion of serine to glycine. I read it with interest and, initially, with consent. Suddenly, something happened. One moment I thought: 'That's neat.'; the next: 'But it's wrong.'; the next: 'Citrate!' It may have taken five seconds, perhaps less. A day or two later I sent off my letter to *Nature*[2].

Why did I leave it (almost[3,4]) at that? Until I received, a few days after publication of my note, an excited letter from Sir Hans Krebs (then at Sheffield), I had little notion of the size of iceberg beneath that tip, regarding my idea as no more than an amusing piece of stereochemical logic and its consequences for asymmetric synthesis as merely an obvious corollary. And I was, by then, deeply involved with other lines of research which, if they have proved to be less sensational, have been satisfying in requiring far greater intellectual effort. 'Three-point attachment' was a gift, out of the blue, for which I have never felt able to claim much credit.

Yet I had, I suppose, unwittingly prepared myself for the three-dimensional visualisation that it required. As an undergraduate student I had enjoyed (and had been excellently taught) the intricacies of stereochemistry. During the war, on daily walks between my digs and place of work, I had amused myself by building, in my head, possible models (all quite wrong[5]) of protein structure. And I was, of course, well aware of the problem, at that time, of the place of citrate in the Krebs tricarboxylic acid cycle.

Is there a chronometer hidden deep in the Sun?

R. H. Dicke
Joseph Henry Laboratories, Physics Department, Princeton University, Princeton, New Jersey 08540

No support is found for the conventional view of the sunspot cycle, that there exists a large random walk in the phase of the cycle. Instead, both sunspots and the [D/H] solar/terrestrial weather indicator seem to be paced by an accurate clock inside the Sun.

IT has long been believed that "the sunspot disturbances, like the eruptions of a geyser, are inherently only roughly periodic"[1]. Observations show a large variation in the ~11 yr half-cycle period, "the observed intervals ranging all the way from 7.3 to 17.1 yr"[1]. Kiepenheuer[2] has described the sunspot cycle as follows: "It was previously believed that the sunspot cycle resulted from the superposition of different periodic cycles.... Since then it has become clear that the rise and fall in the number of spots is due to a number of practically independent individual processes. Thus the idea of a true periodic phenomenon was dropped in favour of the so-called 'eruption hypothesis'. On this hypothesis, each cycle represents an independent eruption of the Sun which takes about 11 yr to die down". This conception of an irregular sunspot cycle, implying a random walk in the phase of the cycle, seems to agree with the Babcock theory and with subsequent modifications of the theory. According to the Babcock theory the poloidal magnetic field remnant of one half-cycle (~11 yr) provides the seed field

0028-0836/78/0276—0676$01 00

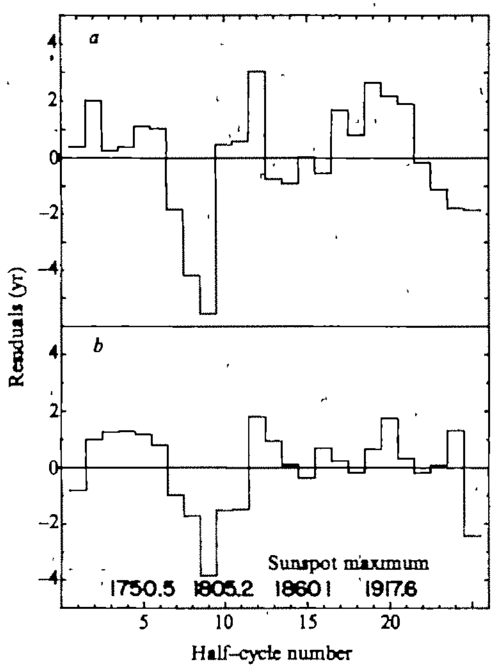

Fig. 1 *a*, Residuals (phase errors) calculated as $\delta y = y - y_0 - p(n-1)$, where y_0 and p are obtained from a least square fit of $y_0 + p(n-1)$ to y, the years of sunspot maxima. *b*, δy from equation (3).

for the generation of the toroidal magnetic field of the next half-cycle by differential winding. If, due to some vagary of the turbulent motion in the outer convection zone of the Sun, a cycle eruption should be late this lateness would be passed on to all subsequent sunspot cycles. Thus, according to the Babcock theory the sunspot cycle should undergo a random walk in phase relative to a high-precision clock.

Is a random walk in phase observed? Starting with the sunspot maximum of 1761.5 there occurred a remarkable series of three very short half-cycle periods, with an average length of 8.9 yr, after which sunspot maximum occurred ~5.6 yr too early. But this was followed by a 17.1-yr half-cycle that completely corrected the phase error. It is as though the Sun 'remembered' the correct phase for 27 yr and then suddenly reset the sunspot cycle (see Fig. 1*a*).

Statistics of the sunspot cycle

If the sunspot cycle were to be timed by some high-*Q* internal oscillator, how would we account for the remarkably large fluctuation in the intervals between sunspot maxima? One possible explanation is that the transport of magnetic field from the deep interior to the surface requires a long time and that this time interval is subject to irregularities induced by turbulence in the convective layer. In this case it might be expected that the transport interval would be lesser the greater the amount of magnetic flux floating to the surface. The phase error in the year of sunspot maximum should then correlate with the sunspot number (with a negative correlation coefficient).

To test this hypothesis the expression

$$y_0 + p(n - n_0) + r(R - \bar{R}), \text{ with } \quad n_0 = 1 \tag{1}$$

is fitted by least squares to y_n (ref. 3), the years of sunspot maxima, starting with 1705.5 ($n = 1$). Here $n = 1, \ldots, 25$, R is the sunspot number of the sunspot maximum and $\bar{R}$ is the average of the 25 values of R (ref. 3). The results are:

$$\begin{aligned} y_0 &= 1{,}704.30 \pm 0.59; \quad p = 11.136 \pm 0.042 \\ r &= -0.0397 \pm 0.0081, \end{aligned} \tag{2}$$

with an unbiased estimate of the error in y of $\sigma_y = 1.45$ yr. The validity of the least-square fit and the error estimates depends on the normality of the distribution of the residuals

$$\delta y = y - y_0 - p(n - n_0) - r(R - \bar{R}) \tag{3}$$

and their independence: δy is shown in Fig. 1*b*. The distribution is found to be approximately normal in form and the autocorrelation function shows only one (2σ) significant peak. The sunspot number estimates for the first few half-cycles may be substantially less reliable than the latter values. Omitting the first four half-cycles gives essentially the same results (equation (2)).

The coefficient r in equation (1) appears to be significant at the 4σ level. Hence we define a corrected year of the sunspot maximum by

$$\bar{y} = y - r(R - \bar{R}) \tag{4}$$

This is the best estimate of the time kept by an internal clock in the Sun, if there is such a clock.

Several statistical tests can be applied to the residuals δy (equation (3)) to help decide whether or not the fluctuations in y represent the random walk in phase required by the 'eruption hypothesis'. The first test is the number of times δy changes sign. The data (Fig. 1*b*) show 10 sign changes. A Monte Carlo calculation based on a gaussian distributed random walk in phase yields 6.1 ± 2.3 crossings, but uncorrelated gaussian fluctuations yield 12.7 ± 2.5 crossings. The independent hypothesis is slightly favoured.

The second test compares two measures of the fluctuation, the mean square residual δy_n (from equation (3)) and the mean square value of $(\delta y_n - \delta y_{n-1})$. With all 25 of the sets of sunspot data, δy_n yields the ratio 0.87 for the above two measures. With the 3σ fluctuation at $n = 9$ omitted (that is, set equal to zero) the ratio is 0.65. Assuming independent, normally distributed fluctuations in y_n, the ratio of the expectation values of the two above mean squares is $(N^2 - 1)/2(N^2 + 2N + 3)$, which for $N = 25$ is 0.46. Assuming a random walk in $\bar{y}$, namely that the error in $\bar{y}_n$ is $\sum_{m=1}^{n} W_m$ with W_m normally distributed and independent and with a uniform variance, the ratio of the expectation values of the two mean squares is $(N+2)(N^2-1)/3(5N^2+6N-3)$, which for $N = 25$ is 1.72. Again the independent fluctuation hypothesis is favoured.

Table 1 Analysis of sunspot data

n_1	n_2	y_0	p	σ
1	25	1704.30±0.55±(2.9)*	11.136±0.039±(0.32)*	1 415 (1.479)
1	13	1704.72±0.90±(2.4)	11.041±0.127±(0.49)	1.710 (1.600)
14	25	1705.52±1.66±(6.6)	11.079±0.088±(0.46)	1 055 (1.456)
5	25	1703.61±0.79±(3.4)	11.176±0.052±(0.38)	1.443 (1 572)
5	15	1703.47±1.57±(3.5)	11.178±0 165±(0.56)	1.728 (1 692)
15	25	1705.95±2.03±(7 7)	11 058±0.105±(0.51)	1 103 (1.526)

* Errors in parentheses assume random walk in phase.

The third test is more powerful. It depends on the fact that a random walk in phase implies a large expected statistical inaccuracy in the values of y_0 and p obtained from the least-square fit

$$y_0 + p(n - n_0) \rightarrow \bar{y} \tag{5}$$

The sunspot data can be analysed as a whole and also in pieces. Substantial inconsistencies would be expected in the results if a random walk in phase occurred. The results are given in Table 1. The more unreliable data are dropped in the last three rows of Table 1.

In all columns of Table 1 the first error (without parentheses) assumes independent fluctuations and the second (with parentheses) assumes a random walk. The standard deviation of the error steps W (last column, parentheses) is chosen to give the same expected r.m.s. value for $(\delta y_{n+1} - \delta y_n)$ as is obtained from the data residuals, equation (3). For independent fluctuations, σ

(last column, without parentheses) is the unbiased estimate of the standard deviation of the error in y, that is,

$$\sigma^2 = N\,\overline{\delta y^2}/(N-2) \tag{6}$$

For independent fluctuations the expected variances of the errors in p and y_0 are respectively

$$\sigma_p^2 = \sigma^2/N\overline{(n-\bar{n})^2} = 12\sigma^2/N(N^2-1) \tag{7}$$

$$\sigma_{y_0}^2 = \sigma_p^2\overline{(n-n_0)^2} = 2\sigma^2(2N-1)/N(N+1) \tag{8}$$

(assuming $n_0 = 1$).

For random walk fluctuations the corresponding expectation values are

$$\sigma_p^2 = 1.2(N^2+1)\sigma^2/N(N^2-1) \tag{9}$$

and

$$\sigma_{y_0}^2 = [(N+1)(2N+1)/6N - \overline{(n-n_0)} + 6(N^2+1)\overline{(n-n_0)}^2/5N(N^2-1)]\sigma^2 \tag{10}$$

$$\sigma_{y_0}^2 = 2\sigma^2(N^3+4N^2+11N-1)/15N(N+1)$$

(assuming $n_0 = 1$).

Table 1 shows that the agreement among the values of y_0 and p is very good, better than would be expected if there were a random walk in phase. But it should be emphasised that all the determinations of y_0 and p in Table 1 are not independent. Also, in line 3, σ_{y_0} is the expected error due to the data (14, 25). But the random-walk phase error at the termination of (1, 13) is the starting error for (14, 25).

A fourth test of the random-walk hypothesis is provided by the unbiased estimate of σ^2, given by equation (6). For a data string broken into m equal pieces the average of the m values of σ^2 should closely approximate σ^2 for the unbroken string, assuming independent fluctuations. With a random walk, the expected mean variance is a factor $(N+2m)/m(N+2)$ smaller. The r.m.s. value of σ from lines 2 and 3 of Table 1 is 1.421 yr, to be compared with 1.415 yr. From the 5th and 6th lines 1.450 yr is obtained, to be compared with 1.443. With random walk errors, 1.044 yr and 1.066 yr would be expected.

All four tests tend to support the independent fluctuation hypothesis, but this support for the 'solar clock' hypothesis is not decisive as the data sample is small and the results could represent a statistical fluke.

Pre-Maunder-minimum sunspot cycle

As a result of Eddy's work[4] it now seems to be well established that very few sunspots were observed from 1645 until 1700. An interesting question concerns the phase and frequency of the pre-minimum sunspot cycle. Was there an internal clock running while the sunspot cycle was substantially turned off?

The telescopic observations during the early seventeenth century were too few to answer this question conclusively. Eddy has found evidence for three sunspot maxima between 1610 and 1645. Taking the sunspot numbers estimated by Eddy at face value, and assuming that $p = 11.136$, gives $y_0 = 1702.2$, with the correction in equation (4). If it is assumed that R was underestimated by a factor of 2, $y_0 = 1703.7$ is obtained. The agreement of these values with y_0 on the first line of Table 1 may mean that a solar clock was running while the surface indications of the cycle were substantially switched off, but the data are too few to provide strong support for this conclusion.

A very long, reliable data base is preferable for an independent analysis of the pre-Maunder-minimum sunspot cycle. The naked-eye sunspot observations of the past 2,000 yr provide one possibility for such an analysis[5]. Unfortunately these large sunspot groups do not always occur at the time of the sunspot maximum and the resulting scatter in epoch seems to be so large as to make these data worthless. Another approach is to use the historical accounts of auroras which are known to correlate with the sunspot cycle. Again there seems to be a large phase uncertainty. There is also an additional uncertainty, that of identification. "Auroras" in ancient Far Eastern accounts are described as "dark vapours", "white vapours", "greyish clouds", and so on.

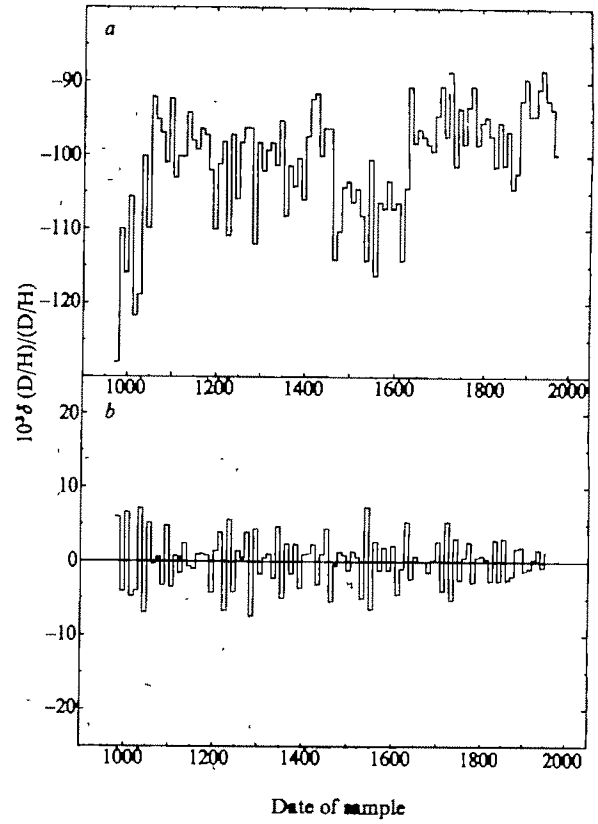

Fig. 2 *a*, Epstein–Yapp[7] [D/H] bristle cone pine data, D. *b*, Epstein–Yapp[7] [D/H] data filtered by subtracting a moving mean $\bar{D}_n = (D_{n-1}+2D_n+D_{n+1})/4$ to give $\delta D_n = D_n - \bar{D}_n$.

The long-debated hypothetical relationship between sunspots and weather might provide the necessary data. This has been a controversial matter: some atmospheric scientists say that the miniscule change in the solar spectrum asociated with the sunspot cycle should not have a substantial effect on the weather, others find evidence for a 22-yr cycle in the weather, and some astrophysicists say that a significant variation in the solar luminosity with the sunspot cycle could not occur. In discussing the 22-yr period in the drought record for the High Plains, Roberts[6] remarked in 1973 that "it will be extremely interesting to see what happens in this region in the period 1974 to 1978". Perhaps this anticipation of the drought of 1976–77 should have been taken seriously. Such a prediction could reasonably have been based on the statistics of previous droughts. The drought years of the nineteenth and twentieth centuries in the High Plains seem to be rather well-established and are: $y = 1823$, 1843, 1868, 1890, 1913, 1934 and 1954 (ref. 6). A least square fit of the form of equation (5) gives

$$\begin{aligned} y_0 &= 1889.3 \pm 0.6 \text{ y} \\ p &= 22.14 \pm 0.28 \text{ y} \\ \sigma_y &= 1.474 \text{ y.} \end{aligned} \tag{11}$$

The expected epoch of the 1975–76 drought is $y = 1977.9 \pm 1.7$. The value of p in equation (11) is in good agreement with twice the values of p in Table 1. If we assume that these periods are the same and adopt the more accurate value $p = 2 \times 11.136$ yr as the cycle period (Table 1, line 1), we obtain $y_0 = 1889.3 \pm 0.5$ and $\sigma_y = 1.375$. The drought epoch closest to 1705 is 1711.1, at the time of the sunspot minimum.

The δ[D/H] indicator

The data from which conclusions can be drawn concerning the phase and frequency stability of the pre-Maunder sunspot cycle are given in Fig. 3*a* of ref. 7. This shows the sequential variations in the deuterium/hydrogen ([D/H]) ratio of a set of 10-yr samples of cellulose nitrate obtained from two bristle cone pines that cover 1,000 yr of time without gaps. A 60-yr interval of the 1,000-yr span overlaps data from the two trees and gives consistent results[8]. For conciseness I shall use D to designate the δ[D/H] indicator, the fractional variation in the [D/H] ratio relative to [D/H] of a standard mean ocean water. Expressed in parts per thousand, this indicator is $D = 10^3\,\delta[D/H]/[D/H]$.

Yapp and Epstein[9] have noted that the [D/H] ratio found in precipitated water varies with both atmospheric temperature and mean surface oceanic temperature, and they have demonstrated that such a variation shows up in the [D/H] ratio found in the cellulose of plants that incorporate the precipitated water during their growth. The variation of D with atmospheric temperature, expressed as a mean slope is $\langle dD/dT\rangle \approx 5.4\ \mathrm{deg}^{-1}$ (see Fig. 10 of ref. 9). Epstein and Yapp[7] have demonstrated a connection between their indicator and the weather. The missing element is a convincing argument that this indicator is related to the solar cycle.

Figure 2*a* is Fig. 3*a* of ref. 7 replotted. The approximately 20-yr period is clearly visible. The power spectrum of D shows a strong peak with a 22 yr period (Fig. 4 of ref. 7). This analysis is repeated here at a higher resolution and after filtering D by subtracting a moving mean $\bar{D}$. δD is shown in Fig. 2*b*. Figure 3 shows the power spectrum of δD. The principal peak occurs at an interpolated frequency of $0.04472\ \mathrm{yr}^{-1}$ and the corresponding half-period is 11.181 yr. The agreement with p in the first line of Table 1 is excellent. This close agreement and the narrowness of the peak in Fig. 3 provide substantial support for the argument that there is a causal relationship between the sunspot cycle and the [D/H] indicator, and therefore with the weather. The spectral peak has the same width at half maximum as that of a sinusoidal oscillation observed for 1,000 yr. The existence of a purely terrestrial meteorological resonance of such high Q seems very unlikely. For the resonance frequency to accidentally agree with the sunspot cycle frequency with a 1σ accuracy of 0.5% seems equally unlikely.

Because of aliasing by the 10-yr sampling period the above interpretation of the frequency of the spectral peak is not unique. However, filtering by the 10-yr average substantially eliminates all but one of the alternative frequencies ($0.05528\ \mathrm{yr}^{-1}$) which does not seem to be the correct interpretation.

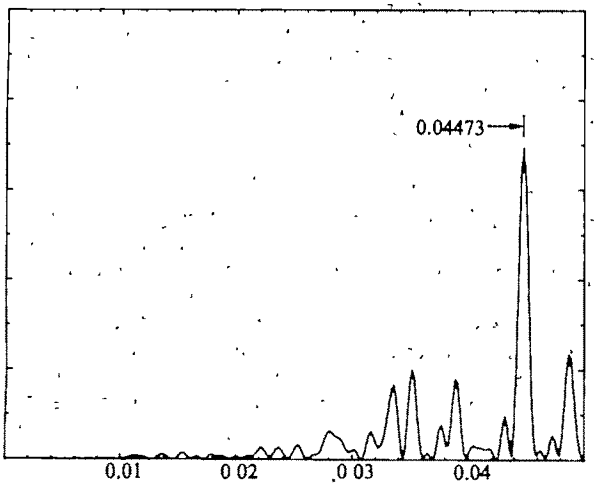

Fig. 3 The power spectrum of δD of Fig. 2. the main peak occurs at the solar cycle frequency (given by the top line of Table 1) to the statistical accuracy of the latter.

Additional support for the assumption that the Epstein–Yapp data provide information about the solar cycle is found in the apparent "finger-print" of the Maunder minimum in the data. These data (Fig. 2*a*) show a pronounced step upward in D after 1625, shortly before the start of the Maunder minimum. The cause of the step is unknown but cannot be due to the change in sample source (change in trees); conceivably it might be related to the Maunder minimum (S. Epstein, personal communication). At 1645 there occurs the start of a 50-yr interval (during the Maunder minimum) with very little variation in D, the only interval of that type in the 1,000-yr span. This quiet interval ends in 1695, just before the return of normal sunspot activity.

We shall tentatively assume a causal relationship between the solar cycle and the weather and treat the Epstein–Yapp data as a solar-cycle indicator. It should be emphasised that this does not imply that the sunspots or other surface manifestations of solar activity are directly responsible for the variation in [D/H]. And the phase of the [D/H] variation need not correspond with the phase of the spot eruption. As noted above the prominent spectral peak found in Fig. 3 is characteristic of a sinusoidal oscillation. The small, narrow secondary peaks of various heights are characteristic of a contamination of the signal by gaussian noise. If random-walk fluctuations in phase should occur the spectral character of the signal would be expected to be significantly different from the peak in Fig. 3. A complex multiple peak resonance with several peaks rising out of a broad low base is normally expected. This is illustrated in Fig. 4.

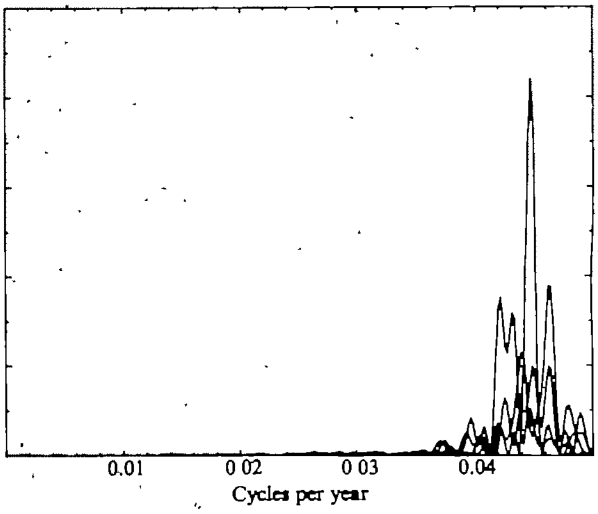

Fig. 4 The power spectra of 'dummy data', computed assuming a constant amplitude oscillation of frequency $0.04473\ \mathrm{yr}^{-1}$ and a random walk in phase. The variance of the random-walk steps $(1.402)^2/10\ \mathrm{yr}$ is equivalent to the random-walk variance $(1.479)^2$ in Table 1. Four randomly chosen examples are superimposed.

We can now examine the Epstein–Yapp data for frequency and phase stability. From equations (7)–(10) the difference between the errors expected under the eruption hypothesis and the solar clock hypothesis are more extreme the longer the data span, the error ratio being approximately proportional to the length of the span. To examine the frequency stability the frequency $\nu = \omega/2\pi$ and the coefficients c_0, c_1 and c_2 are adjusted by least squares in the fit

$$c_0 + c_1 \cos \omega(t - t_0) + c_2 \sin \omega(t - t_0) \rightarrow \delta D \qquad (12)$$

(assuming independent fluctuations) where $t_0 = 1705$. This gives $\nu = 0.044722 \pm 0.000082\ \mathrm{yr}^{-1}$ for the full data set ($n_1 = 1$, $n_2 = 98$) and a corresponding half-period of 11.180 ± 0.021 yr. (Compare with Table 1, first line.) For the first half of the data ($n_1 = 1$, $n_2 = 49$) we obtain $\nu = 0.04500 \pm 0.00019\ \mathrm{yr}^{-1}$ and for the second half $\nu = 0.04429 \pm 0.00023\ \mathrm{yr}^{-1}$. For the intervals (1, 25), (25, 49), (50, 74) and (74, 98) the frequencies are 0.04443 ± 0.00062, 0.04585 ± 0.00040, 0.04455 ± 0.00053 and $0.04415 \pm 0.00070\ \mathrm{yr}^{-1}$ respectively.

Table 2 Analysis of [D/H] data

n_1	n_2	c_1	c_2	σ_D	δ
1	98	1.11 ± 0.39	-2.47 ± 0.38	2.687	$-66° \pm 8°$
1	49	1.20 ± 0.62	-3.02 ± 0.60	3.011	$-68° \pm 11°$
50	98	1.00 ± 0.48	-1.91 ± 0.47	2.344	$-62° \pm 13°$
24	73	1.01 ± 0.53	-2.84 ± 0.55	2.683	$-70° \pm 10°$
1	33	1.85 ± 0.85	-3.06 ± 0.79	3.308	$-59° \pm 13°$
34	66	0.27 ± 0.59	-3.18 ± 0.64	2.476	$-85° \pm 11°$
66	98	1.52 ± 0.53	-1.46 ± 0.49	2.059	$-44° \pm 14°$
1	25	1.99 ± 1.01	-2.77 ± 0.96	3.412	$-54° \pm 16°$
25	49	0.87 ± 0.80	-3.31 ± 0.83	3.425	$-75° \pm 13°$
50	74	0.93 ± 0.69	-2.61 ± 0.73	2.774	$-70° \pm 15°$
74	98	1.40 ± 0.66	-1.32 ± 0.61	1.926	$-43° \pm 18°$

Adopted frequency, $\nu = 0.044722$ y^{-1}.

The agreement of the various values of ν with each other is much better than would be expected with a random walk in phase. Despite the slightly high frequency for the (25, 49) interval, the frequency determinations are internally consistent assuming independent fluctuations. To test for phase stability we adopt $\nu = 0.044722$ yr^{-1} and obtain the results shown in Table 2. In Table 2 the last column is the phase lag (in degrees) of the oscillation (relative to the time zero 1705). (A phase angle of $\delta = -66°$ corresponds to a maximum in δD at 1701.) The amount of stability of phase shown in Table 2 is consistent with uncorrelated fluctuations and is greater than that expected under the random-walk hypothesis.

The Epstein–Yapp data are consistent with the hypothesis that the solar cycle persisted through the Maunder minimum. Additional support for this conclusion is found by Mitchell and Stockton in the tree-ring data[10]. It is found that the power spectra of indices derived from the variations in the widths of successive tree rings exhibit strong but broad 22-yr peaks which seem to be due to the solar cycle[11].

Conclusions

From this it may be concluded that: (1) the sunspot cycle shows no statistical indication of a random walk in phase; (2) it appears to exhibit large fluctuations in phase relative to some internal oscillator in the Sun; (3) the large magnitude of some of the phase errors (as great as 5.6 yr) suggests that there may be a long delay in the transport of magnetic field to the surface of the Sun from the interior; (4) there is a good correlation of this delay interval with the sunspot number and presumably with the amount of magnetic flux; (5) there are several indications that the solar cycle persists through the Maunder minimum. The signal strength and the precision of the 22.36 ± 0.04-yr period seen in the Epstein–Yapp [D/H] data, the narrowness of the spectral peak and the tight agreement with the 22.27 ± 0.08-yr magnetic sunspot period strongly support the hypothetical connection between weather and the solar cycle.

A Glacial Mediterranean

Jörn Thiede

Department of Geology, University of Oslo, PO Box 1047, Blindern, Oslo 3, Norway

Glacial Mediterranean palaeo-oceanography has been reconstructed from planktonic foraminifers once living in this small ocean. Inferred sea surface temperatures ranged from 13 °C in the Alboran Sea to 18 °C in the Levantine Sea during the winter and from 19 to 26 °C respectively during the summer. An influx of cool, fresh surface water from the Aegean Sea disturbed this gradient in the eastern Mediterranean.

THE Mediterranean is a small elongate ocean basin separating dry, arid and hot North Africa from humid to semiarid, temperate to subtropical Europe, and is therefore a sensitive climatic boundary at present. As a marine basin it is subdivided by shallow sills into a series of deep troughs (Fig. 1), and exchanges its water masses with the Atlantic Ocean through the Strait of Gibraltar, to a minor degree with the Black Sea through the Bosporus and with the Red Sea through the Suez Canal. During the Quaternary the pathways between the various basins of the Mediterranean, and the connection to the Atlantic, must frequently have been much narrower and more restricted than at present due to the eustatic lowering of the Glacial sea levels at the same time as the Black Sea became a fresh water or saline lake[1]. The mode of water exchange through the Strait of Gibraltar is largely climatically controlled[2]: North-east Atlantic surface waters which are relatively cool and of normal oceanic salinity, flow into the Mediterranean where evaporation exceeds precipitation and fresh water input from the various rivers. The excess inflow is partly balanced by outflowing Mediterranean subsurface waters which are dense due to their high salinity and relatively warm. They spill over the sill at Gibraltar (330 m), sink to a water depth interval[3] of ~500–1,500 m and can be traced as a separate intermediate water mass over wide regions of the Atlantic Ocean. Any change of this balance which might have occurred during the climatic pulsations of the late Quaternary, must have had important implications for the vertical water mass structure of the entire North Atlantic Ocean. There is an intense dispute about the possibility of a reversed current regime in the Strait of Gibraltar during Glacial episodes[4,5].

Mediterranean planktonic foraminifers

Here I use planktonic foraminiferal assemblages to reconstruct the Glacial palaeo-oceanography of the Mediterranean. Samples have been dated by various methods (litho- and biostratigraphy, oxygen isotope ratios, radiocarbon dating) and will be discussed elsewhere together with a detailed account of the foraminiferal data. The most important recent advance in the stratigraphy of late Quaternary Mediterranean pelagic sediments, which enabled the correlation of these sediments to the contemporaneous record in other oceans[6], is the recognition of the coincidence of the elevated oxygen isotope ratios marking the last Glacial maximum with the occurrence of the coolest planktonic foraminiferal faunas[7–9]. Glacial core levels have been sampled and planktonic foraminiferal taphocoenoses have been counted at all locations (Fig. 2*a* and *b*) except the position off Israel where published data have been used[10]. Faunal counts

0028-0836/78/0276—0680$01.00

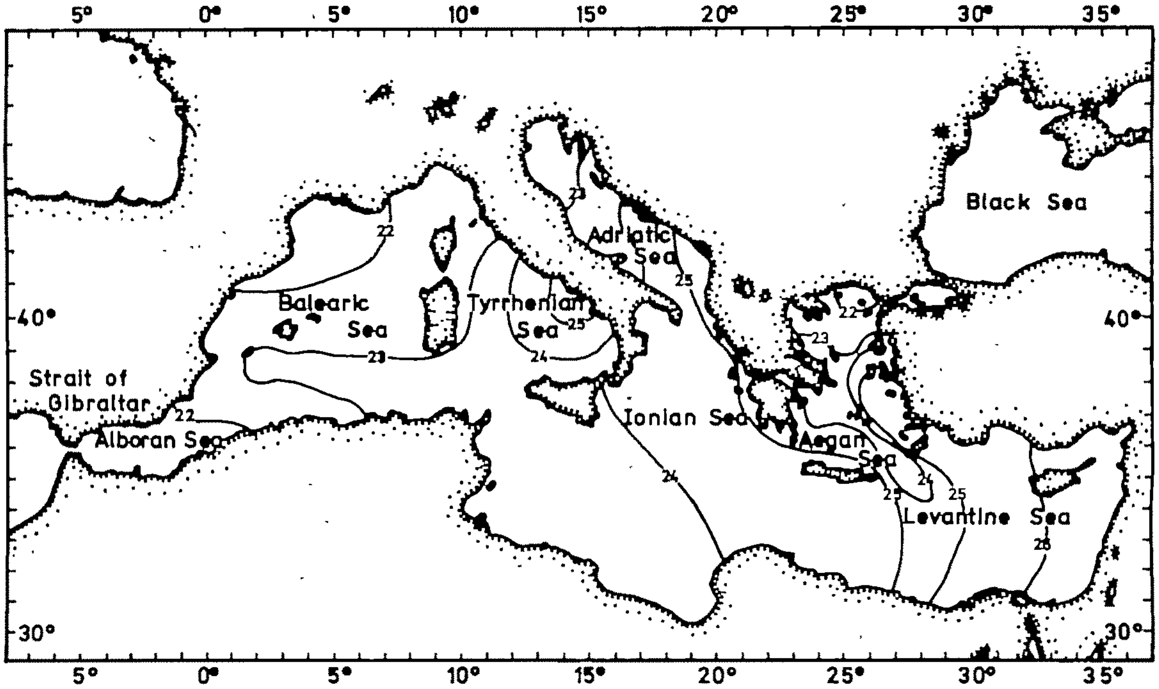

Fig. 1 Modern summer (August) sea surface temperatures in the Mediterranean after Bruns[40] and names of major basins as referred to in the text.

and palaeo-oceanographic estimates of 33 locations provide the data base for this reconstruction of the Glacial Mediterranean.

Planktonic foraminifers and other planktonic fossils have been used successfully in many parts of the world ocean[11] for palaeo-oceanographic reconstructions, but these methods have encountered difficulties when applied to regions close to the continents[12] and in marginal basins. The late Quaternary foraminiferal faunas from the East and West Mediterranean have frequently been described since the Swedish Deep Sea Expedition assembled the first substantial series of sediment cores from this region[13,14]. However, most of these studies[15] have looked at the late Quaternary fluctuations as a series of events affecting the depositional regime at a particular core location. In this study, emphasis is placed on drawing a regional, quasi-synoptic picture of the palaeo-oceanography of the entire Mediterranean Sea during the last Glacial by collecting as many samples as possible from cores where I could confidently identify this stratigraphic interval, and by using Glacial planktonic foraminiferal faunas to define the distribution of important surface water masses during the 18,000 yr BP time slice.

Atlantic surface waters transport planktonic foraminifers into the Mediterranean[16], where rich faunas dwell in the surface water masses above all the central troughs. Planktonic foraminifers, which inhabit the modern oceans from polar to tropical latitudes[17], are confined to water masses with a relatively narrow range of salinities. They cannot therefore survive or establish autochthonous faunas in marginal seas such as the North Sea or Baltic Sea[18,19] where the seawater is considerably less saline than in the open ocean, or in the Persian Gulf, where high salinities prevent the establishment of autochthonous faunas (although living planktonic foraminifers drift into this marginal basin from the Indian Ocean)[20,21]. It is therefore important that planktonic foraminifers inhabited the Mediterranean throughout the late Quaternary[22,23] despite evidence from the surrounding land masses suggesting major climatic fluctuations in this region[24,25]. The common presence of these fossils in the Glacial and Interglacial Mediterranean sediments, despite the periodically restricted pathways between the North-east Atlantic and the Alboran Sea, and between the west and east basins is remarkable because it implies that it was the Mediterranean sea surface temperature regime that responded to these climatic fluctuations rather than the salinities, although detailed investigations of the oxygen isotope ratios of planktonic foraminifers also suggest important variations of sea surface salinities[26]. The western basins are now populated by tropical, subtropical and temperate faunas while tropical faunas prevail in the East Mediterranean. A typical warm water representative of these faunas is *Globigerinoides ruber* which is a frequent component of Tyrrhenian Sea, Adriatic Sea and East Mediterranean surface sediments[27,28]. During the last Glacial this and other tropical species were restricted almost entirely to the Ionian and Levantine Seas[10,13,14,22].

Although the Balearic Sea is situated just south of a region of major alpine glaciation during the last ice age, and although we know that the Bay of Biscay was filled with polar water masses during this period[12,29], it was surprising that the typical planktonic foraminiferal marker species of polar water masses, the left-coiling phenotype of *Globoquadrina pachyderma*, never became abundant in the Mediterranean except in a small area of the Tyrrhenian basin. In the Glacial North-east Atlantic, water masses with this species have been traced as part of the eastern boundary current system along the Iberian continental margin, but they do not seem to have protruded southwards beyond the south-west tip of the Iberian peninsula. Cool to temperate species inhabited the Glacial West Mediterranean with species such as *Globigerina bulloides*, *G. quinqueloba*, *G. pachyderma* (right) and *Globorotalia inflata* being typical faunal components. Note that some of these species have also occurred in considerable abundance in the northern parts of the Levantine and Ionian Seas as well as in the Adriatic[30].

Glacial sea-surface temperatures in the Mediterranean

Although Mediterranean faunas posed a considerable problem in early attempts at synoptic palaeo-oceanographic reconstructions, my studies apparently revealed many similarities to equivalent Atlantic faunas. I have therefore attempted to explain the composition of the Mediterranean faunas statistically in terms of North Atlantic assemblages and to apply transfer functions[31] which had been developed to describe quantitatively the North-east Atlantic late Quaternary palaeo-oceanography[12], to Glacial Mediterranean planktonic foraminiferal

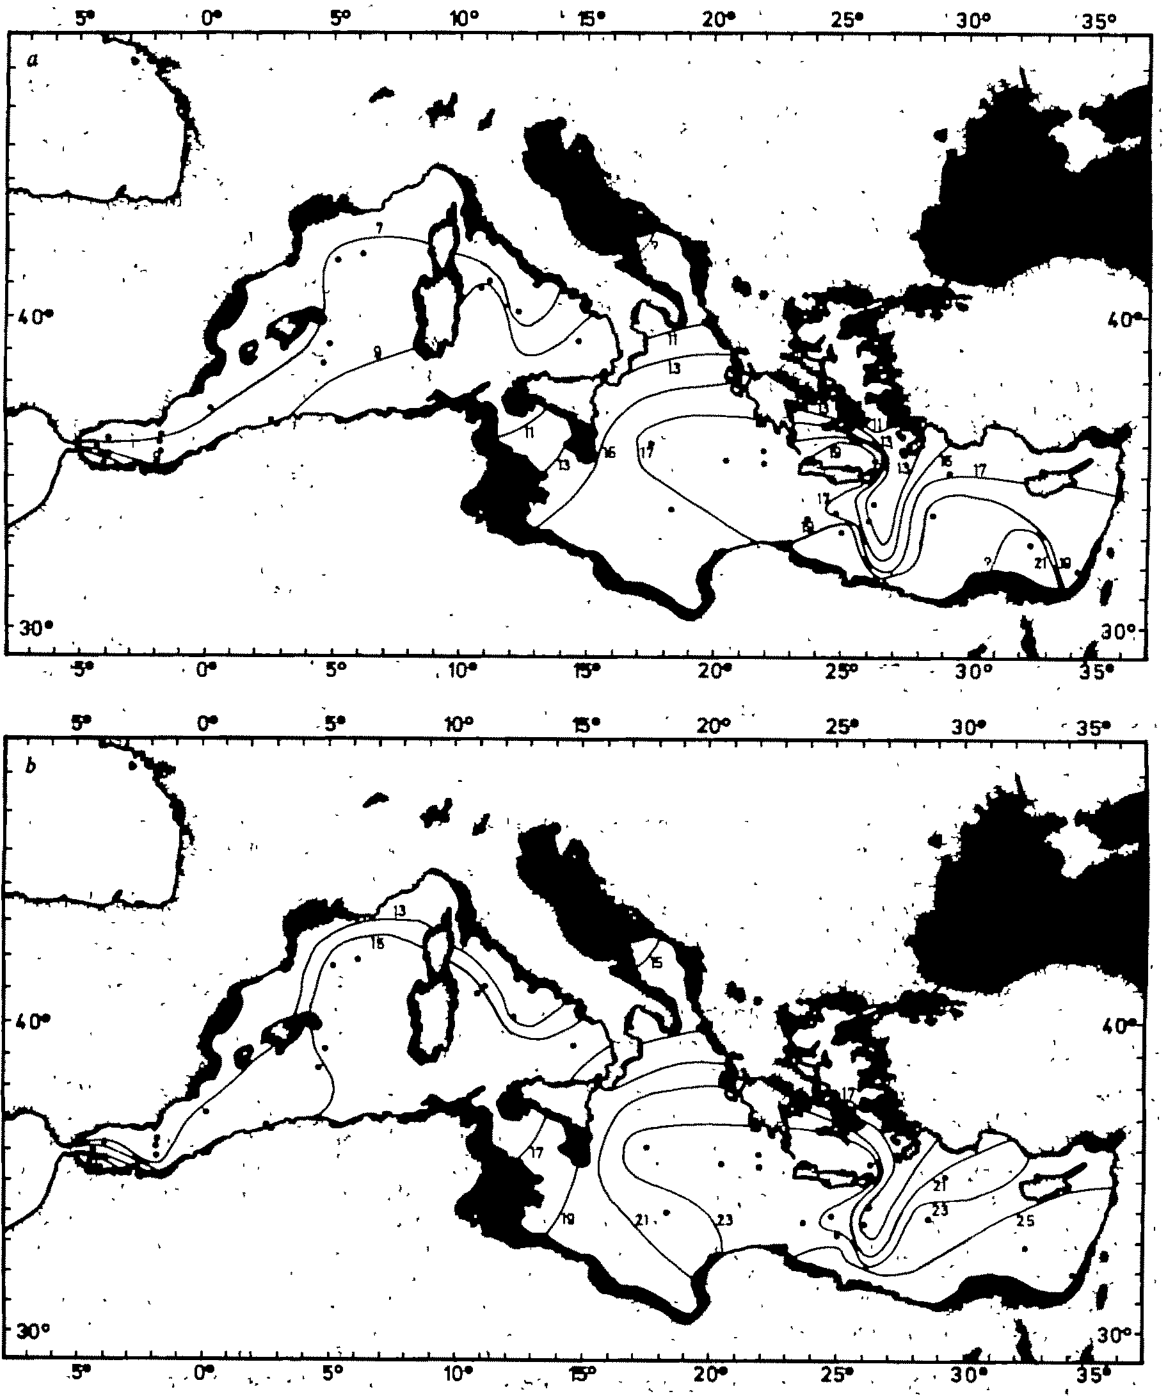

Fig. 2 Sea-surface temperatures in the Mediterranean during the peak of the last Glacial ~18,000 yr ago. *a*, During the Glacial winter (February). *b*, During the Glacial summer (August). Dots mark the positions from where Glacial core levels have been obtained. The blackened areas mark schematically changes of the Mediterranean coast lines due to the lowered Glacial sea levels.

shell assemblages. For this the data base which had been developed for the North Atlatic[32], has had to be modified by selecting the data from the North-east Atlantic and by adding a considerable number of sample points from the Bay of Biscay and from the Ibero–Moroccan continental margins[12]. These modifications were intended to recognise and allow for the fact that it is the surface waters of the North-east Atlantic eastern boundary current sustem that are diverted into the Mediterranean. Downcore studies suggest there is good reason to believe that the Glacial mode of water exchange between the Mediterranean and the North-east Atlantic resembled the modern current regime in the Strait of Gibraltar[5] when the >300 m deep strait was probably only half as deep than at present[33]. The Mediterranean can also be considered as a small ocean basin with plankton assemblages slightly different from those of the open pelagic environment, because they are affected by the hydrography of epicontinental water masses which are never very far away in this small ocean.

Otherwise the evaluation of the micropalaeontological data has followed established procedures[31] which allowed me to estimate quantitative values for past oceanographic variables. They combine Q-mode factor analysis with regression and classification analysis. The Q-mode factor analysis with the program CABFAC[34] produces two matrices. The varimax factor matrix defines the importance of North-east Atlantic planktonic foraminiferal assemblages – factors at each sample location[12], a matrix of factor scores indicates the contribution of each category = planktonic foraminiferal species to each factor. The relationship among assemblages and hydrographic variables has been established by multiple regression analysis, in this case North-east Atlantic summer (August) and winter (February) sea-surface temperatures. The resulting transfer functions have recently been used to reconstruct the Glacial North-east Atlantic[12]. In this study classification analysis has been applied to project Glacial Mediterranean downcore samples into the model derived from the modern North-east Atlantic. This step allows the factor loadings to be estimated on the basis of the predefined matrix of factor scores in each of the Mediterranean samples. Finally, these estimated factor loadings have been fed into the equations obtained by regression analysis, to calculate values of summer and winter sea-surface temperatures in the Glacial Mediterranean.

The degree to which planktonic foraminiferal faunas in each sample are explained by the Q-mode factor model, is expressed as communality both in factor and classification analysis. Thus, the calculated communalities of the Glacial Mediterranean faunas can tell how successfully they are explained by the North-east Atlantic surface assemblages. Several stations have been found where the faunas have not been explained satisfactorily by the model applied, as indicated by low communalities (cut off point in general at 0.7). These stations are located mainly in the marginal basins along the northern shores of the Mediterranean, for example in the Adriatic Sea. I conclude, therefore, that these faunas do not have an analogue in the modern North-east Atlantic. Other samples with low communalities have been observed in regions where frequent turbidites (for example, in the abyssal plains) suggest the contribution of displaced sediment components. Samples with low communalities have therefore been eliminated from further analysis.

This attempt to reconstruct the palaeo-oceanography of the Glacial Mediterranean reveals several other deficiences. Although sea-surface temperatures have been compared here with Atlantic data, other hydrographic variables might have been more appropriate. Distortions of the oxygen isotope ratios of planktonic foraminiferal shell material suggest important changes of sea surface salinities[26]. The eastern Mediterranean is today characterised by seasonal differences of temperature which are higher than those in the North-east Atlantic, because the influence of the continental climate over the adjacent land masses has an important impact on the temperature regime. The model applied here might therefore be incapable of generating sufficiently high seasonalities for the Glacial Eastern Mediterranean.

However, there are enough cores whose faunas are explained very well by the above described model (Fig. 2). The factor loadings which have been estimated in the classification analysis-step, reveal a simple regional distribution pattern of planktonic foraminiferal assemblages in the Glacial Mediterranean. Two relatively cool assemblages are concentrated in the north-west basins, an intermediate one occurs as a belt across the central part while the tropical assemblage is confined to its south-west region. Polar assemblages are virtually missing from the entire basin.

The results of attempts to contour the temperature estimates for the Glacial winter (February) and summer (August) are given in Fig. 2*a* and *b*. The temperature range spanned from 7 °C in the north-west basin to >20 °C in the south-east basin during the Glacial winter. While the temperature increased eastwards in a fairly regular fashion in the Balearic basin, the pool of warm surface waters in the Ionian and Levantine basins reveals a considerable structure because of the disruptive intrusion of a cool surface water mass from the Aegean Sea. During the summer the entire Mediterranean apparently warmed up considerably, but the basic pattern of surface-water temperatures was still preserved. The steepest temperature gradients are found close to the connection between the East and West Mediterranean basins[35], but the incursion of the cool surface water from the Aegean basin is also visible during the Glacial summer. Comparison between the modern (Fig. 1) and Glacial (Fig. 2*b*) sea-surface temperature shows how and where the most drastic temperature changes from the Glacial to the modern situation have occurred. The similarity of the pattern, although not of the absolute temperature values south of the Aegean Sea, is particularly noteworthy. The temperatures in the Glacial Alboran Sea compare well to those of the adjacent North-east Atlantic. The Bay of Biscay[12] was probably a few degrees colder than the North-west Mediterranean during Glacial times. Although we know that ice-rafted debris can be traced in the Glacial levels of cores along the north-west African continental margin as far as South Morocco[36], coarse ice-rafted terrigenous detritus has not been found in the corresponding samples from the Western Mediterranean. The higher sea-surface temperatures in the Glacial Balearic basin are also supported by the virtual absence of the polar planktonic foraminifer *G. pachyderma*.

A source for the water mass protruding from the Aegean into the Levantine basin deserves further attention. Previously it had been assumed that the fresh water influx was due to high discharge rates of the Nile river[9], but the pattern which has now been established by means of foraminiferal studies, strongly suggests a northern source[37,38]. It is commonly believed that the land areas north of the Glacial Mediterranean were much drier than at present[24,39]. If this is so, the source for this important influx of cool and probably comparatively fresh water[26] into the Aegean Sea has to be sought in the hinterland of the Glacial Black Sea which as a lake was overflowing into the Mediterranean[37,38].

The regulatory region of the *trp* operon of *Serratia marcescens*

Giuseppe F. Miozzari & Charles Yanofsky

Department of Biological Sciences, Stanford University, Stanford, California 94305

The nucleotide sequence of the regulatory region of the trp *operon of* Serratia marcescens *is presented. It contains a transcription termination control site in the transcribed leader region preceding the first structural gene of the operon as well as a regulated promoter/operator transcription initiation region. The structural organisation of the leader region differs substantially from that of* Escherichia coli.

In *Escherichia coli*, transcription of the *trp* operon is regulated at a promoter/operator[1–4], and also at an attenuator[5,6]. The attenuator is a site within the transcribed leader region of the operon at which transcription is either terminated or allowed to proceed into the structural genes. Termination at this site seems to occur in response to the availability of charged $\mathrm{tRNA}^{\mathrm{Trp}}$ for protein synthesis[7,8]. RNA transcribed from the *trp* leader region contains a functional ribosome binding site[9–11], and may code for a short leader peptide with two adjacent tryptophan residues[12].

Comparison of the nucleotide sequences of the *trp* promoter/operator/leader region in *E. coli* and the related enterobacteria *Salmonella typhimurium* and *Shigella dysenteriae* have been useful in identifying the functionally important sequences within these regions[12–14]. The enterobacterium *Serratia marcescens* is more distantly related to *E. coli* and the sequence of its *trp* regulatory region would provide an interesting comparison. Although little is known of the structural organisation of the *trp* genes in *S. marcescens*, mutant and physiological studies indicate that many of these genes are arranged in an operon whose expression is coordinately regulated in response to changes in tryptophan concentration[15–17]. We have cloned a portion of the *S. marcescens trp* operon on plasmids and present here the nucleotide sequence of the regulatory region.

Cloning and restriction of *trp* operon

Chromosomal DNA of *S. marcescens* wild-type strain SM6 was cleaved with restriction endonuclease *Sal*I and the fragments inserted into the *Sal*I site of pBR322 (ref. 18). Plasmids carrying a functional *S. marcescens trpE* gene were isolated from the ligation reaction by selecting Trp^+ transformants of an *E. coli* recipient strain in which most of *trpE* is deleted (see legend to Fig. 1). Each of several Trp^+ transformants examined carried plasmids containing one or two inserts into the *Sal*I site of pBR322. One typical representative, pGM14, was chosen for further characterisation. It carries a single 3,000-base pair insert; a restriction map of this fragment is shown in the top portion of Fig. 1. Although pGM14 confers prototrophy to *trpE*$^-$ recipient strains, it does not complement lesions in any of the other *trp* structural genes, indicating that *trpE* is the only intact *S. marcescens trp* gene on pGM14.

S. marcescens trpE was located within the 3,000-base pair *Sal*I fragment by constructing derivatives of pGM14 carrying portions of the insert. One such plasmid, pGM63, carries only the right-hand half of the 3,000-base pair insert, from the *Sal*I site to the first *Eco*RI site (Fig. 1), but retains a functional *trpE*. This 1,500-base pair fragment could code for a protein of approximately 60,000 molecular weight, the estimated size[21–23] of *S. marcescens* anthranilate synthetase component I, the *trpE* product. This suggests that the *Eco*RI and *Sal*I sites delimiting the 1,500-base pair fragment must be very close to the ends of *trpE*. This was confirmed by DNA sequence analysis and comparison of the nucleotide sequences with the known N-terminal amino acid sequences of the *S. marcescens trpE* and *trpG* proteins[23]. The DNA sequence at the *Eco*RI end of the fragment correlates precisely with the amino acid sequence at the beginning of the *trpE* protein, with the *Eco*RI site preceding the AUG start codon by 20 base pairs. There are two back-to-back potential AUG translation start codons at the beginning of *trpE* (Fig. 2). Using the first, the N-terminal amino acid sequences of the *trpE* proteins of *S. marcescens*, *E. coli* and *Sal. typhimurium* align perfectly[23]. The *Sal*I end of the fragment is located about 30 base pairs beyond the start of *trpG*, the structural gene for anthranilate synthetase component II, which must therefore follow *trpE* in the *trp* operon of *S. marcescens*[16,26] (C.Y., G.F.M., G. Bennet and M. van Cleemput, in preparation). Thus, the 1,500-base pair *Eco*RI–*Sal*I fragment carries *trpE* intact. However, the 20 base pairs preceding the start of *trpE* are insufficient to function as a promoter and we must therefore assume that in plasmid pGM63 *trpE* is expressed from a plasmid promoter. Most of the regulatory region of the *S. marcescens trp* operon is therefore absent from plasmid pGM63, but is contained in the parent plasmid pGM14. A detailed restriction map of the DNA region immediately preceding the *Eco*RI site is shown in the bottom portion of Fig. 1.

DNA sequence of the promoter/operator/leader region

A DNA segment of approximately 380 base pairs around the *Eco*RI site at the beginning of *trpE* was sequenced using several overlapping restriction fragments (bottom portion of Fig. 1). Large portions of the DNA sequence of the entire $Eco\mathrm{RI}_{260}$ fragment and of the initial part of *trpE* (Fig. 2) are highly conserved between *S. marcescens*, *E. coli* and *Sal. typhimurium*[3,12,13]. This suggests that the overall organisation of the regulatory region of the *trp* operon is similar in the three organisms. In particular, a DNA segment centred around base pair −10 of the *S. marcescens trp* operon is almost perfectly conserved. In *E. coli* and *Sal. typhimurium* this region is essential for *trp* promoter and operator function[3,4,13,14]. Indeed, *E. coli* Trp repressor will protect the *Hpa*I site at positions −9 to −14 and the *Tac*I site (−20 to −23) but not the *Hin*cII site (−32 to −37) or the *Hae*III site (+15 to +18) of *S. marcescens* from cleavage by the respective restriction enzymes (data not shown). As in the case of *E. coli* and *Sal. typhimurium*, the *S. marcescens trp* operon contains a leader region which separates the promoter/operator region from the start of the first structural gene, *trpE*. In *E. coli* and *Sal. typhimurium* this region is transcribed[27] and contains the *trp* attenuator[6,12].

In vitro transcription of the initial portion of the *S. marcescens trp* operon

When DNA fragments containing the *trp* promoter/operator/leader region of *E. coli* or *Sal. typhimurium* are transcribed with purified RNA polymerase *in vitro*, a major RNA transcript is produced as a result of transcription termination at the *trp* attenuator[28]. To determine whether a similar termination site is

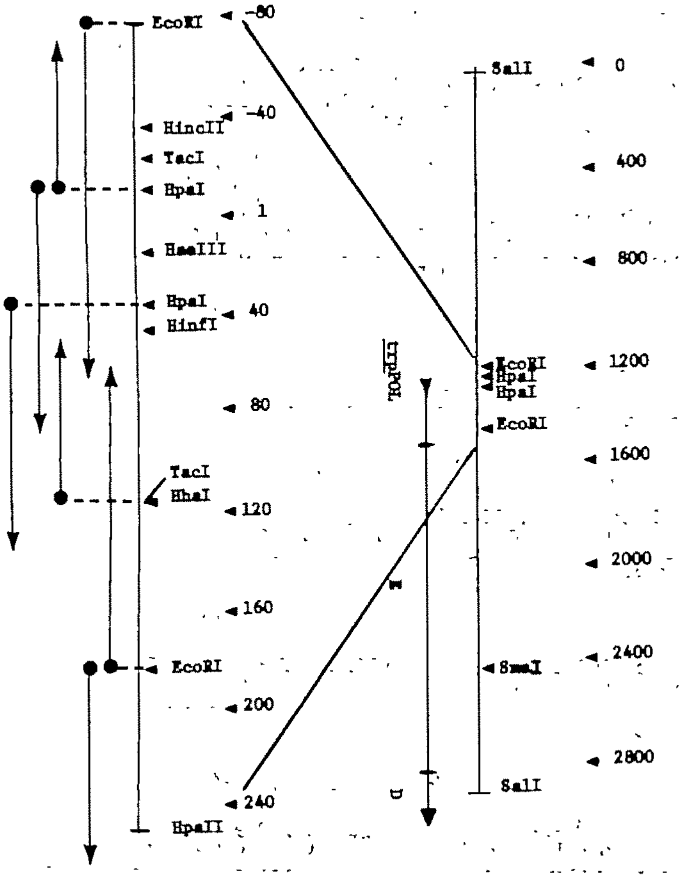

Fig. 1 Restriction map of a cloned fragment containing the initial portion of the *S. marcescens trp* operon. Chromosomal DNA of *S. marcescens* was prepared by the method of Miura and Sato[19]. 10 μg of chromosomal DNA and 5 μg of pBR322 DNA were digested with restriction endonuclease *Sal*I, phenol extracted, ethanol precipitated and resuspended in 250 μl of ligation buffer (60 mM Tris–HCl *p*H 7.6, 10 mM $MgCl_2$, 10 mM dithiothreitol, 1 mM ATP). The mixture was incubated in the presence of T4 DNA ligase for 2 h at 13 °C. Ligation was stopped by ethanol precipitation and the pellet resuspended in 100 μl TE-buffer (10 mM Tris–HCl *p*H 7.9, 0.1 mM EDTA). 20 μl were used to transform *E. coli* strain JA221 (C600 r^-m^+ Δ*trpE5 leu recA*) to prototrophy. About 20 ampicillin-resistant, tetracycline-sensitive Trp^+ transformants were obtained. As Trp^+ transformants were readily obtained using several restriction enzymes and two plasmid vehicles we believe that the cloned *S. marcescens* fragments contain unchanged chromosomal sequences. The transformation frequency (10 transformants per μg DNA) was comparable to that reported for *E. coli* DNA[20]. The restriction map of the insert carried by plasmid pGM14, a typical representative of the plasmids isolated from the Trp^+ transformants, is shown in the top portion of the figure. The arrow indicates the site of initiation and the direction of *trp* mRNA transcription. The bottom portion of the figure shows a detailed restriction map of the promoter/operator/leader region of the *S. marcescens trp* operon. Numbering starts at the presumed site of transcription initiation (position +1). The arrow indicates the direction and length of sequencing runs.

present in the leader region of the *S. marcescens trp* operon we isolated and transcribed various DNA fragments spanning the presumptive *trp* promoter/operator region. The transcripts obtained with the *Eco*RI_{260} and the *Hpa*II_{400} fragments are shown in Fig. 3. The *Eco*RI fragment ends at position +185 in the leader region whereas the *Hpa*II fragment extends to position +252 in the initial part of *trpE* (Fig. 1). Both fragments yield an approximately 175-nucleotide RNA transcript as the major product of *in vitro* transcription, together with a larger transcript of ~185 nucleotides for the *Eco*RI fragment and ~250 nucleotides for the *Hpa*II fragment. As the 175-nucleotide transcript is also observed when larger DNA fragments or plasmid pGM14 are used as DNA templates for *in vitro* transcription (results not shown), we conclude that the *S. marcescens trp* leader region contains a transcription termination site approximately 175 base pairs downstream from the transcription initiation site. Indeed, the DNA region between base pairs +150 and +180 shows close homology to the termination regions in the *E. coli* and *Sal. typhimurium trp* leader regions (Fig. 2)[12,28]. The larger transcripts observed with both the *Eco*RI_{260} and the *Hpa*II_{400} fragments (Fig. 3) presumably arise by readthrough beyond the transcription termination site to the end of the DNA fragments. Quantitative measurements indicate that there is about 30% readthrough at the *S. marcescens trp* leader termination site *in vitro*. In *E. coli* and *Sal. typhimurium* readthrough at the *trp* attenuator *in vitro* has been estimated at 5% and 30%, respectively[28]. In experiments in which we have examined the function of the *S. marcescens trp* attenuator in *E. coli*, tryptophan starvation relieved transcription termination and the increase in operon expression apparently exceeded that typical of the *E. coli trp* operon. Hutchinson and Belser[16] had previously noted that the regulatory response of *S. marcescens* to exogeneous tryptophan was five times more sensitive than that of *E. coli*.

Features of the promoter/operator region

Both DNA·RNA hybridisation data[29] and protein primary structure comparisons[23,30,31] indicate considerable evolutionary divergence in the *trp* operon of *S. marcescens* relative to those of *E. coli* and *Sal. typhimurium*. Conserved regions in such distantly related organisms may indicate functional importance. In particular, one might expect key sequences involved in recognition and binding of RNA polymerase and/or regulatory proteins to be conserved.

The promoter/operator regions of the *trp* operons of *E. coli* and *S. typhimurium* share a recognition sequence for *Hpa*I (GTT↓AAC) (Fig. 2). The integrity of this 6-base pair sequence seems to be essential for both operator and promoter function, as a single base pair alteration within this region severely affects both functions[14] (G. Zurawski, D. Elseviers and C.Y., unpublished). Of 19 base pairs in the symmetrical regions surrounding this *Hpa*I site, 18 are conserved between *E. coli*, *Sal. typhimurium* and *S. marcescens* (Fig. 2). *E. coli* Trp repressor recognises this DNA segment in all three organisms. In *S. marcescens* it protects two restriction sites—the *Hpa*I site between −9 and −14 and the *Tac*I site between −20 and −23—from cleavage by the respective enzyme. The only difference between *S. marcescens* and *E. coli* in this region, a CG instead of a TA base pair at position −16, does not seem to affect repressor–operator recognition significantly, although it does reduce symmetry. Interestingly, an *E. coli* mutant with a different base pair change at the same position (TA → GC) is O° (ref. 4), and Trp repressor does not protect its *Hpa*I site against cleavage by *Hpa*I (K. D. Brown and C. Y., unpublished results). The lack of sequence conservation from base pair −21 to −31 (Fig. 2) is consistent with the view that this DNA segment is not involved in repressor recognition[4]. The rightward endpoint of the region required for operator function in *E. coli* has been mapped to between positions −5 and +1 (ref. 4). The pattern of sequence conservation in this region (Fig. 2) suggests that residues to the right of position −3 may not be required for operator function. Taken together, these findings indicate that the *trp* operator of all three organisms is contained within the highly conserved DNA segment between residues −3 and −21.

RNA polymerase–promoter recognition and formation of a functional initiation complex are thought to involve sequence specific contacts with a DNA sequence around position −35 and with the 20-base pair DNA segment which immediately precedes the transcription initiation site[13,32]. The pattern of sequence conservation between *E. coli*, *Sal. typhimurium* and *S. marcescens* is consistent with this notion. In addition to the highly conserved sequence between positions −3 and −21 the three organisms have an identical 6-base pair sequence between positions −32 and −37 (Fig. 2). This sequence, GTTGAC,

Fig. 2 Nucleotide sequence of the regulatory region of the *S. marcescens trp* operon. The sequenced segment comprises the promoter/operator/leader region and the initial portion of *trpE*. This subdivision is indicated by the arrows. Numbering starts at the presumed site of transcription initiation (residue +1). Clusters of base pairs that have been conserved between *E. coli*, *Sal. typhimurium* and *S. marcescens* are indicated by black bars. With two exceptions (Gln instead of His at residue no. 6 and Asp instead of Asn at residue no. 19) the underlined portion of the predicted amino acid sequence of *trpE* is identical to the previously published amino acid sequence at the N-terminus of *S. marcescens* anthranilate synthetase component I (ref. 23). The two differences are indicated by an asterisk. The DNA sequence predicts a recognition site for restriction endonuclease *Hae*III (GGCC) between positions 149 and 152. We find no cleavage by *Hae*III at this site. As the *Hae*III recognition sequence partially overlaps an *Eco*RII recognition sequence (CCTGG) between positions 146 and 150, we assume that methylation of the complementary C residue at position 149 prevents recognition by *Hae*III. DNA sequence analysis was carried out by the method of Maxam and Gilbert[24]. Details of this and related procedures such as restriction site mapping, isolation of DNA fragments, phosphatase treatment, polynucleotide kinase reactions and agarose and polyacrylamide gel electrophoresis are given elsewhere[3,25].

recognised by *Hin*dII and *Hin*cII, occurs at the same relative position in several unrelated promoters[33]. The *S. marcescens trp* promoter is efficiently recognised by *E. coli* RNA polymerase both *in vivo* and *in vitro*. This suggests that the RNA polymerase of both organisms has similar requirements for its interaction with promoters. Initiation of transcription of the *S. marcescens trp* operon is likely to occur at the position previously determined for *E. coli*[27], particularly as 28 of 30 base pairs surrounding the potential initiation site (−21 to +9) are conserved. The importance of the highly conserved DNA segment between positions 1 and 8 following the transcription initiation site (Fig. 2) is unclear, as a deletion which replaces the DNA sequence beyond position +1 by a foreign sequence has no effect on either promoter or operator function in *E. coli*[3].

Leader region

A 200-base pair leader region separates the site of transcription initiation of the *S. marcescens trp* operon from the start of the first structural gene *trpE*. There are many functional and structural similarities between this DNA segment and the leader regions of the *E. coli* and *Sal. typhimurium trp* operons[12] and the *E. coli phe* operon[34]. They contain an attenuator region which terminates transcription in a run of TA base pairs preceded by a GC-rich segment. Although the residues at which transcription terminates have only been determined experimentally for the *E. coli* leader transcript[35,36], extensive sequence conservation in the region that contains the termination site in *E. coli* (Fig. 2; residues 140–180) suggests that in *S. marcescens* transcription termination must occur within the run of TA base pairs between residues 169 and 175. This is consistent with the estimated length of 175 nucleotides for the terminated *S. marcescens trp* leader transcript synthesised *in vitro*.

Like the other *trp* leader transcripts, that from *S. marcescens* could generate considerable secondary structure. The structure depicted in Fig. 4 is remarkably similar to those proposed for the *trp* and *phe* leader transcripts of *E. coli* and the *trp* leader transcript of *Sal. typhimurium*[28,34]. It has alternative stem and loop structures involving a GC-rich segment (residues 150–156) able to pair with two different regions of leader RNA. Base pairing with residues 162–168 generates the smaller stem and loop structure immediately preceding the 3′-OH end of the leader transcript. This structure has a calculated free energy of formation of $\Delta G \cong -17\ \mathrm{kcal\ mol^{-1}}$ (refs 37, 38). Studies of termination relief mutants suggest that the integrity of the analogous structure in the *E. coli trp* leader transcript may be essential for efficient transcription termination[39]. Residues 136–156 can also pair with residues 99–120 to form the alternative larger stem and loop structure, with a free energy of $\Delta G \cong -22\ \mathrm{kcal\ mol^{-1}}$. With the exception of the sequences corresponding to the unpaired loop regions (residues 121–135 and 157–161), the entire DNA segment responsible for the formation of the alternative stem and loop structures (residues 100–170) is highly conserved between *S.marcescens*, *E. coli* and *Sal. typhimurium* (Fig. 2).

The *trp* and *phe* leader regions examined have in phase translation start and stop codons and may thus code for a short leader peptide. In *E. coli*, and AUG-centred ribosome binding site early in the *trp* leader region[9] can function efficiently in initiation of translation both *in vivo* and *in vitro*[10,11]. Two tandem tryptophan codons are found in the sequence coding for the putative *trp* leader peptides of *E. coli* and *Sal. typhimurium*[12], whereas seven phenylanine residues are clustered in the C-terminal portion of the predicted *phe* leader peptide of *E. coli*[34]. Two potential AUG translation start codons are present in the early part of *S. marcescens trp* leader RNA (Fig. 4). Both are in phase with the tandem tryptophan codons (residues 80–85) and a UAA translation stop codon (residues 110–112). The number of amino acid residues predicted for the *S. marcescens trp* leader peptide is either 19 or 28, depending on which initiation site is used (Fig. 5). Although in the other *trp* and the *phe* leader transcripts the translation stop codon immediately precedes the region involved in the formation of the alternative stem and loop structures, in *S. marcescens* the UAA stop codon is five amino acid codons beyond this point, within the region of assumed secondary structure (Fig. 4). A highly conserved sequence surrounds the tandem tryptophan codons at residues 80–85 (Fig. 5). The only nucleotide differences between *S. marcescens* and either *E. coli* or *Sal. typhimurium* in this region, U instead of C at position 88 and C in place of U at position 91, do not affect the predicted amino acid sequence. This conserved sequence is in the same position relative to the large stem and loop structure in all three *trp* operons. Although we believe that the extent of translation of the two tryptophan codons is an integral feature of the mechanism governing regulation of transcription termination[40], we cannot explain the extensive nucleotide and amino acid sequence conservation of the region surrounding the tryptophan codons.

Comparison of the initial portion of the *S. marcescens trp* leader region with the analogous regions in both *E. coli* and *Sal. typhimurium* reveals that the *S. marcescens trp* leader region contains a DNA insert of 27 base pairs between residues 9 and 10 of the *E. coli* and *Sal. typhimurium* sequences (Fig. 4). The 7 base pairs preceding this DNA segment (AGTTCAC; residues 2–8) are repeated with one difference at the end of the insert (AGTTAAC; residues 31–37). This extra DNA codes for the first of the two potential translation start codons (residues 26–28) for the *S. marcescens trp* leader peptide. The position of this AUG codon relative to the transcription initiation site is similar to that of the initiator codons for the *E. coli* and *Sal. typhimurium* leader peptides. The second potential start codon for the *S. marcescens trp* leader peptide is between residues 53 and 55 (Fig. 5). The region preceding and including this AUG codon has been moderately conserved (Fig. 2). The region preceding either potential start site for the *S. marcescens trp* leader peptide shows no obvious homology to known ribosome binding sites or to the 3′ end of 16S rRNA[41].

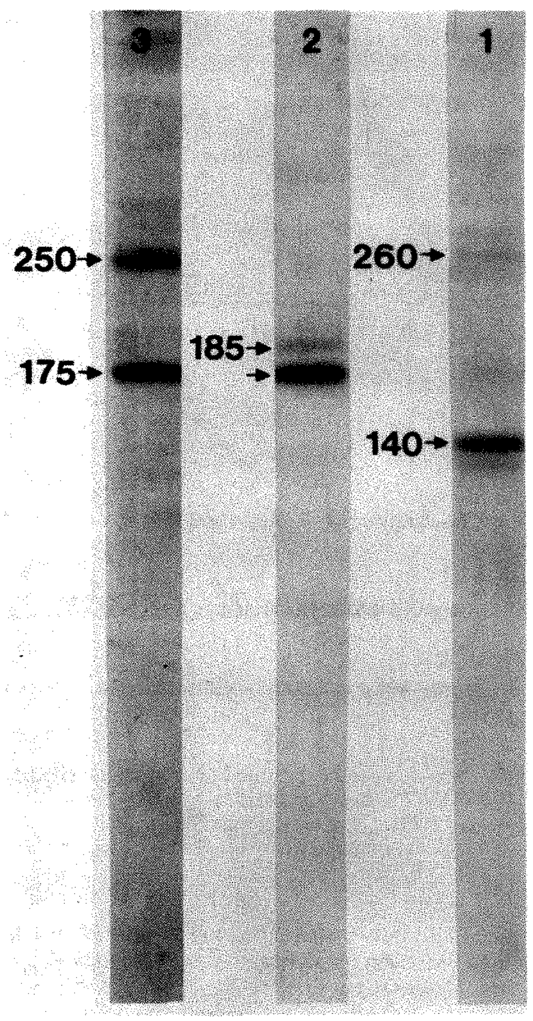

Fig. 3 *In vitro* transcription of DNA fragments containing *S. marcescens trpPOL*. RNA was transcribed from the following DNA fragments: (3) *S. marcescens Hpa*II$_{400}$, (1) *S. marcescens Eco*RI$_{260}$, (1) *E. coli Hpa*II$_{570}$. All fragments contain the regulatory region of the respective *trp* operons. The arrowed numbers indicate the length in nucleotides of the various transcripts. The size of the *S. marcescens* transcripts (slots 3 and 2) was calculated from the known lengths of the transcripts obtained with the *E. coli Hpa*II$_{570}$ fragment[28]. The 175-base RNA bands arise by transcription termination at the *S. marcescens trp* attenuator; the 185- and 250-base RNA bands are the result of transcription beyond the transcription termination site to the end of the respective fragments. The composition of the *in vitro* transcription mixture as well as the separation of the transcription products on polyacrylamide gels has been described[28].

We do not know whether either or both of the potential start sites is used in *S. marcescens*. Lee and C.Y.[28] have proposed a model for the regulation of transcription termination that is based on translation of the leader transcript and a shift between alternative RNA base pairing configurations in this transcript. Recent evidence suggests that base pairing between residues in the large loop of the alternative stem and loop structures and proximal segments of RNA may also be involved in attenuation. Thus, a stable hydrogen-bonded structure involving the large

Fig. 4 Proposed secondary structure of the terminated *S. marcescens trp* leader transcript. The left hand portion of the diagram shows the position of the 27-base pair 'insert' compared to the sequence of the initial portion of the *E. coli* and *Sal. typhimurium trp* leader transcripts. The locations of the two possible translation start codons, the tandem tryptophan codons and the translation stop codon, are indicated. The regions of sequence homology between the insert and the large loop of the alternative secondary structures are indicated by underlining.

Loop of the alternative stem and loop structures and the region containing the seven phenylalanine codons can be drawn for the *phe* operon transcript of *E. coli*[34]. A similar, though weaker, complementarity between the region containing the two tryptophan codons and some of the residues of the large stem and loop exists in the *E. coli* and *Sal. tyhimurium trp* leader transcripts[40]. In *S. marcescens*, the complementarity (between residues 89–95 and 102–108) is restricted to the RNA region distal to the two tryptophan codons. However, a unique feature of the *S. marcescens trp* leader RNA is the strong complementarity between the region of the transcript which forms the large loop and the RNA sequence corresponding to the DNA insert (Fig. 4). Of 17 nucleotides between positions 16 and 32, 14, including the first AUG codon, are complementary to residues 139–123 of the *S. marcescens trp* leader transcript. The calculated free energy of formation of this structure is about -10 kcal mol^{-1}.

Although many aspects of the functional and structural organisation are similar in all *trp* leader regions examined so far, three obvious differences exist between the *trp* leader region of *S. marcescens* and the analogous regions of *E. coli* and *Sal. typhimurium*: (1) an extra segment of DNA, 27 base pairs long, inserted into the early portion of the *S. marcescens trp* leader region; (2) potential base-pairing between nucleotides within this insert and residues in the large loop of the alternative stem and loop structures; (3) the potential of *S. marcescens trp* leader RNA to code for a 19- or 28-residue leader peptide, with a stop codon within the region assumed to be involved in the formation of an alternative stem and loop structure. Despite these differences, the *S. marcescens trp* leader region terminates transcription both *in vitro* and *in vivo*, like the analogous regions in *E. coli* and *Sal. typhimurium*, and the extent of termination *in vivo* is a function of the availability of tryptophan. Our results suggest that regulation of transcription termination at the *trp* attenuator of *S. marcescens* may allow a greater range of expression than is attainable at the *E. coli trp* attenuator. The structural differences between the leader regions of *E. coli*, *Sal. typhimurium* and *S. marcescens* may therefore have developed to allow quantitatively different regulatory responses.

Fig. 5 Predicted amino acid sequences of *trp* leader peptides. The predicted amino acid sequence of the putative *S. marcescens trp* leader peptide (second line) is compared with the predicted sequence of the analogous peptides of *E. coli* and *Sal. typhimurium*. The three peptides share an identical sequence of six amino acids surrounding the tandem tryptophan codons (indicated by a box). The *S. marcescens trp* leader peptide extends five amino acid residues beyond the end of the other peptides at its C-terminus. Depending on which of the two potential translation initiation sites is used, it may start at the same position as the *E. coli* and *Sal. typhimurium* peptides, or it may have nine additional amino acid residues at its N-terminus (indicated in parentheses).

We thank Virginia Horn and Miriam Bonner for technical assistance, and Gerard Zurawski and Eric Selker for their help. This work was supported by grants from the USPHS (GM 09738), the NSF (PCM 77-24333) and the American Heart Association. G.M. was a postdoctoral fellow supported by the Swiss NSF. C.Y. is a Career Investigator of the American Heart Association. These studies were performed in accordance with the NIH guidelines on recombinant DNA research. *E. coli* strain JA221 was obtained from J. Carbon.

The regulatory region of the biotin operon in *Escherichia coli*

Anthony Otsuka & John Abelson

Department of Chemistry, University of California, San Diego, La Jolla, California 92093

It is proposed that the biotin anabolic operon in Escherichia coli *is transcribed divergently from two partially overlapping face-to-face promoters. A mutation that increases transcription* in vivo *creates an additional promoter* in vitro. *The putative operator contains an imperfect palindromic sequence that partially overlaps the promoters. The regulatory and genetic implications of these findings are discussed.*

THE synthesis of biotin in *E. coli* requires the products of the *bio* gene cluster[1,2], which is located at approximately 17 min on the genetic linkage map[3]. Transcription of the *bio* gene cluster is divergent[4,5]. Transcription is initiated between the *bioA* and *bioB* genes and proceeds to the left into *bioA* and, from the opposite DNA strand, to the right into *bioB*, *F*, *C*, and *D*[4,5]. Transcription in both directions is co-repressed by biotin[4,6,7]. Genetic studies by Ketner and Campbell[8,9] have shown that the *bioA* and *bioB* promoters are not independent, as several single mutations which increase *bioA* transcription decrease *bioB* transcription. The operators are not independent; a single mutation results in constitutive RNA synthesis in both directions[9]. In this report, we propose that the *bioA* and *bioB* promoters are situated face-to-face and partially overlap. The operator contains a, hyphenated palindromic sequence that partially overlaps the promoters. This model is similar to one of the three models proposed by Ketner and Campbell[9].

We have evidence that one of the mutations[9] that increases leftward transcription, *bioP*98, may create a second leftward promoter. In addition, we report the nucleotide sequence of the *bio* regulatory region.

Identification and isolation of the *bio* regulatory region

Among the *bio* regulatory mutants isolated by Ketner and Campbell[9] were promoter down mutants that were unable to transcribe in either direction (Table I). The promoter down mutation, *bioP*132, was recovered by transduction with λ*bio*1 and the resultant phage, λ*bio*132, was found to contain a DNA insertion element[9], presumably within the *bio* regulatory region. (To simplify identification of bacteriophage λ*bio*1 derivatives, a shorthand description will be given to each transducing phage. This numbering[9] does not infer isolation of an independent transducing phage with endpoints of the *bio* substitution different from λ*bio*1. The phages described in this article are as follows: λ*bio*132 is λ*bio*1*bioP*98*bioP*132 and λ*bio*234 is λ*bio*1*bioP*98*bioO*34. The DNA insertion, which seems to be IS*1* from restriction site data, serves as a convenient physical marker for detecting restriction fragments that contain the *bio* regulatory region. Various restriction digests[10] of λ*bio*1 and λ*bio*132 DNA were compared by gel electrophoresis[11,12]. The *Hin*dII sites in the *bio* substitutions of these phages are shown in Fig. 1. Further analysis resulted in the partial restriction map in Fig. 2.

It was necessary to locate the *bio* control region by another method as it is possible that the IS element could inactivate transcription by a mechanism unrelated to its insertion. Proof that fragments containing the site of the DNA insertion also contain the *bio* regulatory region came from the comparison of *in vitro* transcription of wild type (λ*bio*1) and mutant (λ*bio*234) DNA fragments. Transcription of the *Hin*dII fragment from λ*bio*1 that was postulated to contain the control region (from the position of IS*1* in an analogous fragment from λ*bio*132) gave a major transcript of 170 nucleotides. This transcript terminated at the *Hin*dII site and hybridised to the l-strand of *bio* transducing phage DNA, identifying it as a leftward (*bioA*) transcript.

On the other hand, a DNA fragment from λ*bio*234, which contains the promoter up mutation, *bioP*98, and the operator constitutive mutation, *bioO*34, gave two major transcripts, one of 170 nucleotides and another of 150 nucleotides, both hybridising to the *l*-strand of *bio* transducing phage DNA. The longer transcript was initiated at the wild-type start site and the shorter transcript was initiated 24 nucleotides down from the wild-type

Table 1 Three classes of *bio* regulatory mutants

	Presence of *galT* and *E*	Phenotype Low biotin	Phenotype High biotin	Properties
Parent (*bio*Δ61)	+	Gal$^-$	Gal$^-$	Gal$^-$ at low biotin due to insufficient transcription.
	−	Gal^S	Gal^R	
I Promoter A up mutants P98 (spontaneous) P2, P10, P43 (2AP)	+	→Gal$^+$	Gal$^-$	*bioA* mRNA increased 4- to 6-fold, *bioB* mRNA decreased to one-third wild type.
	−	Gal^S	ND	
II Promoter A down mutants P130, P131, P132 (2AP)	+	Gal$^-$	Gal$^-$	No transcription in either direction, IS element in regulatory region.
	−	→Gal^R	Gal^R	
III Operator constitutive mutants O34, O38, O49, O99 (spontaneous)	+	Gal$^+$	→Gal$^+$	Constitutive in both directions, same amount of *bioA* mRNA as *bioP*98, *bioB* mRNA increased twofold.
	−	Gal^S	Gal^S	

The data in this table are summarised from ref. 9. The *bio* operons are under negative control with biotin as the co-repressor. Low levels of biotin (1.6 nM) permit synthesis of biotin, while high levels of biotin (41 nM) repress synthesis. Both a positive and negative selection technique were used to isolate control mutants. The parent strain contains a deletion (*bio*Δ61) which fuses *bioA* to *galE* and places the galactose operon under the control of the *bio* regulatory system. A portion of both *bioA* and *galE* are deleted in this strain. If *galK* is expressed, for example at low biotin concentrations, in the presence of galactose (glycerol is the carbon source) the accumulation of galactose-*1*-phosphate prevents growth. This is a negative selection for galactose utilisation. If, on the other hand, *galE* (and *galT*) is supplied by a transducing phage integrated at a distant site, galactose is metabolised and can serve as the sole carbon source. This is a positive selection for galactose utilisation. By using these two selections, Ketner and Campbell[9] isolated the three classes of regulatory mutants listed. In each case, an arrow designates the ancestry of each of the mutant types. Thus the second and third classes of mutants all contain the *bioP*98 mutation. Abbreviations are as follows: Gal$^-$, unable to utilise galactose; Gal$^+$, able to utilise galactose; Gal^S, sensitive to galactose; Gal^R, resistant to galactose; 2AP, induced with 2-aminopurine; ND, no data.

start site. These results correlate *in vitro* and *in vivo* transcriptional changes. If the shorter transcript were due to *bioP*98 rather than *bioO*34, it would explain the total fourfold increase in leftward transcription in strains containing *bioP*98 which does not change further on the formation of the double mutant, *bioP*98, *bioO*34. The *bioP*98 mutation may increase transcription by creating a second leftward promoter, *bioP*98, whilst maintaining the wild-type *bioA* promoter. A precedent for overlapping promoters has been established in the galactose operon of *E. coli*[13].

Early transcription experiments were carried out in the presence of heparin to produce selective transcription[14]. In these conditions, very little *bioB* transcription occurs. Later experiments were carried out in the absence of heparin, and transcription was initiated by the addition of magnesium chloride[15]. Selective transcription was maintained by using higher salt concentrations (see legend to Fig. 2). In this case, rightward transcription is increased to about one-half the level of leftward transcription.

Although we do not have direct genetic evidence for the positions of the *bioA* and *bioB* promoters, we have investigated the transcription of the *Hin*fI fragment and the *Hae*II fragment that contain the control region (Fig. 2). These two fragments together encompass a region 340 nucleotides to the left and 500 nucleotides to the right of the *bioP*98 promoter. In magnesium start conditions, two major transcripts could be found in each case; one leftward and one rightward. Transcripts from different fragments were shown to have the same start sites. Individual transcripts from the *Hin*fI fragment were hybridised to the separated strands of the *Hha*I fragment containing the control region and the unhybridised portions of the RNA removed with RNase[16]. Fingerprints[17] of the RNase-protected transcripts were essentially identical to those from transcripts from the *Hha*I fragment itself. Thus there are apparently only two major promoters in the 650-base pair *Hin*fI fragment.

Organisation of the regulatory elements

Both DNA strands of the *bio* control region have been sequenced. The sequence between the *Fnu*EI and *Hph*I sites is presented in Fig. 3. There are several prominent features of the control sequences. First, there is a large imperfect palindrome near the *in vitro* mRNA start sites. The promoters are situated face-to-face and partially overlap. Both promoters overlap the palindrome, but the *bioB* promoter does so to a much greater extent. The promoter sites are A-T rich (46/65 base pairs) and are flanked by relatively G-C rich sequences (16/25 and 9/19 base pairs). The first AUG codons of the two mRNAs are 86 nucleotides apart on the DNA sequence. It is not yet known whether these represent the initiation sites for the synthesis of the *bioA* and *bioB* gene products.

Positions of the promoters

There are three possible positions for the two *bio* promoters: (1) overlapping; (2) face-to-face and non-overlapping; (3) back-to-back and non-overlapping[9]. The first model can be divided into a spectrum of models that range from overlapping face-to-face to overlapping back-to-back promoters. The proposed promoters are found to conform to the first model with face-to-face

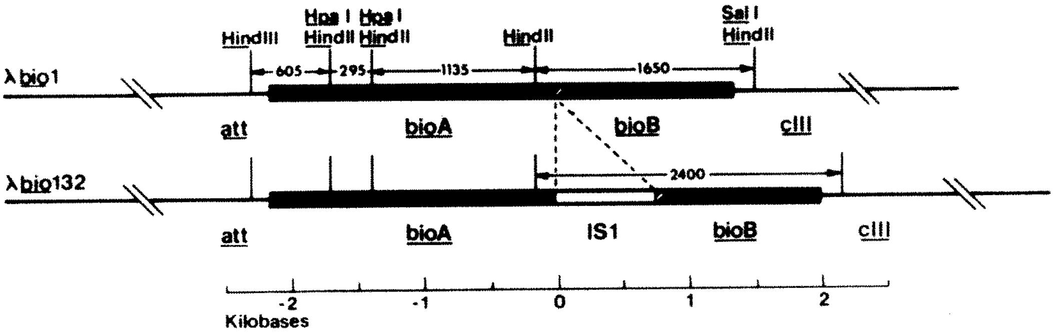

Fig. 1 The position of IS*1* (open line) within the *bio* substitution (thick line) in the λ*bio*132 genome locates the *bio* regulatory region (shaded line). The *Hin*dII and *Hin*dIII sites within and adjacent to the *bio* substitution are shown. The endpoints of the *bio* substitution in λ*bio*1 and λ*bio*132 are within 480 base pairs of the *Hin*dIII site and 530 base pairs of the *Sal*I site. The IS*1* elements in λ*bio*132 and in λ*dgalT*:S188 (ref. 20) are in the same orientation relative to the λ genome. The orientation of IS*1* is then '+' with respect to the *E. coli* genome[50]. Fragment sizes are in base pairs. The centre of the large 'palindrome' in the regulatory region is the zero point of the scale.

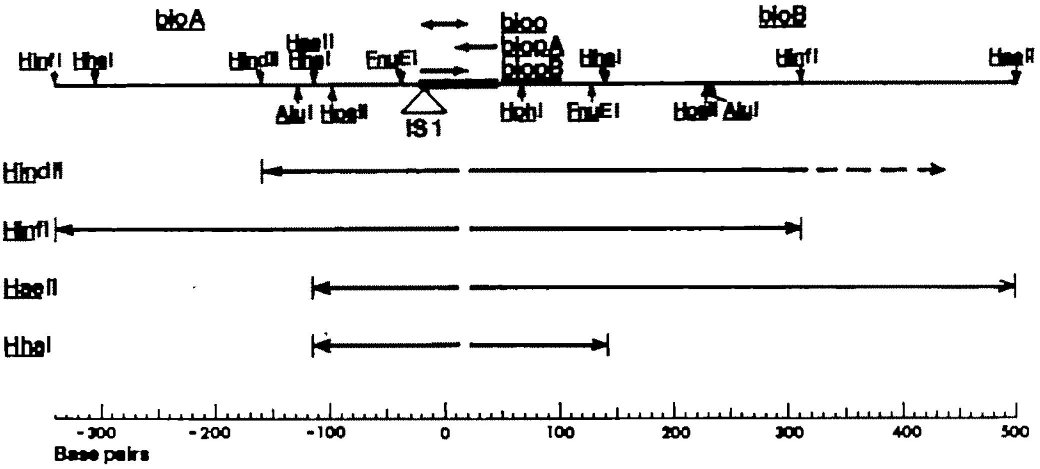

Fig. 2 The first restriction sites flanking the *bio* regulatory region are shown for several sequence-specific endonucleases. The thick line represents the region containing the *bioA* and *bioB* promoters. The positions of the promoters (*bioPA* and *bioPB*) and the operator (*bioO*) are shown by arrows above the linear map (see Fig. 3). The approximate position of the IS*1* insertion in *bioP*132 is shown. The lower portion of the figure shows the transcripts, (arrows), obtained from each of the wild-type restriction fragments listed at the left Only two initiation sites were observed in the entire 840 nucleotide region that is presented. The rightward transcript from the 1,650-base pair *Hin*dII fragment, represented as a broken line, terminates prematurely at several sites. Transcription experiments were carried out in a final volume of 20 μl with approximately 0.05–0.2 μg of a purified DNA fragment (about 10 nM) in 40 mM Tris-HCl at *p*H 8.0, 100 mM KCl and 10 mM 2-mercaptoethanol. RNA polymerase holoenzyme, 8.6 μg (840 nM or an RNA polymerase-to-DNA ratio of 84:1), was added to the reaction mix and incubated at 37 °C for 5 min. The reaction mixture was then transferred to a tube containing a single [α-^{32}P] ribonucleoside triphosphate at a final concentration of 10 μM for pyrimidine nucleoside triphosphates and 25 μM for purine nucleoside triophosphates, as well as the remaining required ribonucleoside triphosphates at final concentrations of 200 μM. The mixture was then incubated for 5 min at 37 °C and the reaction started by adding $MgCl_2$ to a final concentration of 10 mM. After 20 min of RNA synthesis, the reaction was worked up as described previously[14].

partially overlapping promoters. The *in vitro bioA* and *bioB* mRNA start sites are 10 nucleotides apart on the DNA and the messengers do not overlap. This observation rules out the second model, of two distant face-to-face promoters with overlapping transcripts, which was not ruled out genetically. The third model of two independent and distant back-to-back promoters has been proposed by Das Gupta *et al.*[18] on the basis of electronmicrographic evidence, but it is not supported by the promoter interactions found in the genetic studies[9]. However, the genetic argument requires that the promoters are functionally independent, which is not substantiated in the singular case of the interactive distant back-to-back promoters of the arabinose operons of *E. coli*[19]. Das Gupta and his collaborators believe that the mRNA start sites are about 174 nucleotides apart[18] but we have not found transcripts separated by this distance in our studies. We must assert, however, that only the position of the *bioP*98 promoter can be uniquely and unambiguously determined by mutation. The *bioA* and *bioB* promoters are positioned solely by the fact that *in vitro* transcription starts at two positions within an 840-base pair region that contains portions of the *bioA* and *bioB* genes.

The proposed orientation of the promoters is consistent with the genetic data. The *bioP*98 mutation, which increases total leftward transcription fourfold, decreases rightward transcription to one-third of the wild-type level[9]. Because the promoters overlap, mutations in one promoter may affect the other promoters. It is also possible that operator mutants affect promotion, and promoter mutants may affect repression, as the putative operator partially overlaps the promoters. The binding of RNA polymerase to the *bioA* or *bioP*98 promoters could even sterically prevent binding of RNA polymerase to the *bioB* promoter.

A second genetic observation that is explained by the proposed model has been noted by Ketner and Campbell[9]. The insertion sequence element found in the *bio* regulatory region could inactivate rightward transcription by insertion into the *bioB* promoter and could block transcription from the *bioA* promoter by termination within the IS*1* element. IS*1* is known to give polar mutations when inserted in either direction[20]. In this regard, we have mapped the insertion site to a region near or in the *bioB* promoter and to the left of the *bioA in vitro* mRNA start site (Fig. 2).

Finally, the proposed promoter orientation may explain an observation of Das Gupta *et al.*[18]. They observed transcriptional intermediates using the electron microscope in which one DNA strand had been displaced by an RNA strand synthesised in either direction, but not in both directions. For those intermediates observed, the binding of a second RNA polymerase molecule is precluded because the second promoter is in the form of an RNA–DNA hybrid.

Location of the operator

The selection of operator mutants that are simultaneously constitutive for transcription in both directions suggests that the promoters for both operons must share at least one common operator site[9]. However, studies of the repression of the *bio* operons with biotin analogues suggest the possibility of two independent operators[21]. Preliminary sequence analysis of the double mutant, *bioP*98, *bioO*34, shows two sequence changes. One of these is at position −3 (Fig. 3) and the other is at position +15. They are both located within the imperfect palindrome. We conclude that the imperfect palindrome is at least one component of the operator, but as we have sequenced neither mutation alone we cannot assign each mutation an identity. Because the *bio* repressor has not been isolated, it is not possible to locate the operator by binding studies; however, it is possible to select plasmids containing the *bio* operator by their ability to titrate repressor (A. O. and J. A., unpublished). The *bio* repressor(s), like the *gal*, *trp*, *lac* and λ phage repressors (reviewed in ref. 22), may effect repression by isosterically preventing RNA polymerase binding rather than by allosteric interaction.

Promoter sequences

It is difficult to define the exact molecular interactions between RNA polymerase and a given promoter. The physical limits of promoters have been approximately defined by mutations and binding or protection studies[13,23–43,49]. However, most sequenced promoters have two common interaction sites. These are the Pribnow box[25] and the recognition site[27], both defined by homologies found in sequenced promoters, as well as, to a certain extent, by mutations or protection studies (reviewed in refs 23,24). The Pribnow box is of the form 5'TATRRTR3' (R, a purine nucleotide) and is centred at approximately 10 nucleotides proximal to the RNA initiation site. The A in the second position and the T in the sixth position from the 5' end of the Pribnow box are the most highly conserved bases[13]. In the *bioA* and *bioB* promoters four out of seven bases match the Pribnow paradigm (Fig. 4). There is an A residue in the second position and a T residue in the sixth position of the Pribnow box in each promoter. In the case of the *bioP98* promoter, four out of seven bases agree with the Pribnow sequence. The tentative C to A substitution in the *bioP98* promoter allows agreement with the second nucleotide of the formal Pribnow sequence. Because both the sequenced operator and promoter mutations occur within the *bioP98* promoter, the importance of the substitution at position −3 awaits sequencing of the *bioP98* mutation alone.

The second common feature of most promoters is a recognition site which encompasses about 12 nucleotides centred at approximately position 32 upstream of the RNA initiation site. There are two general types of recognition sites. However, there are some promoters that do not fit into either class very well, for example the *lacI* promoter[42], and others that are between classes, for example the *araB* promoter[43]. Nevertheless, it is convenient to divide the promoters into groups with recognition sequences most closely resembling the sequences TGTTGACAATTT, referred to here as type I promoters[23–35], and those resembling the sequence NNNNNACACTTT (N is any nucleotide), referred to here as type II promoters[13,23,36–41]. The former type is quite often found in bacteriophage promoters[25–33] and the latter in the catabolite activator protein (CAP) regulated sugar utilisation operons[13,23,36–40] in *E. coli*. The *bioA* promoter contains a recognition site that agrees with 9 of the 12 bases in the type I recognition site. However, there are only 5 bases between the *bioA* recognition site and the Pribnow box, in contrast to a distance of 12 to 14 bases for most promoters. Perhaps this distance can be reconciled by the possibility that two different subunits of RNA polymerase act at the two sites. Alternatively, the true recognition site may reside further from the Pribnow box and contain less homology to known recognition sites. The recognition site of the *bioB* promoter matches the type I sequence in five positions. This is not an unusually poor fit as several type I promoters agree with the type I sequence at only six positions[27,33]. The *bioP98* promoter fits at seven positions in the type I recognition sequence. The average match for the type I promoters evaluated here[25–35] is 8 out of 12 positions.

It is difficult to explain the relationship of the *in vivo* transcriptional levels to the primary sequence of the promoters. The *bioA* promoter produces one-twentieth of the molar amount of mRNA, when fully de-repressed in a Bio$^-$ strain, compared to the fully induced *galE* promoter[9]. The *bioA* and *bioB* promoters transcribe at approximately equal efficiencies *in vivo*[4]. The *bioP98* promoter is three times more efficient *in vivo* than the wild-type *bioA* promoter[9]. However, there is no obvious correlation between these promoter sequences and the resulting transcriptional levels. The *bioA* and *bioB* promoter sequences are quite different, yet they produce RNA equally well. It is not clear what features cause these promoters to be twenty times less efficient than the *galE* promoter. Lastly, because the *bioP98* and

Fig. 3 The overlapping face-to-face *bioA* and *bioB* promoters are positioned on the DNA sequence by the 5' ends of the *in vitro* mRNAs as well as homology to other promoters[23–43]. The *bioP98* promoter, created by mutation, is positioned by the 5' end of the mRNA as well as the tentatively assigned base substitutions at positions −3 and +15 found in the double mutant, *bioP98*, *bioO34*. The promoters are defined to be DNA sequences starting from and extending 35 to 40 nucleotides upstream from the initiation site for transcription. This definition is based on studies of DNA regions essential to promoter activity[23]. The *bioB* promoter and the *bioP98* promoter overlap the putative operator to a greater extent than the *bioA* promoter (lines above and below the DNA sequence delineate the imperfect palindrome). Transcription may be repressed sterically either by binding of repressor to the operator or by steric competition of RNA polymerase molecules for one of the several overlapping promoters. Neither the presumptive sequence change in the *bioO34* mutation, which abolishes repression *in vivo*, nor the presumptive *bioP98* sequence change, which increases total leftward transcription fourfold, affects sequences in the recognition sites (open lines) or Pribnow box structures[23] (shaded lines) of the *bioA* or *bioB* promoters. Both strands of the DNA have been sequenced from positions −21 to 53 by the method of Maxam and Gilbert[51]. RNA sequence data from the *bio* transcripts will be presented elsewhere. Sequences that are complementary to the 3' end of 16S rRNA[52] are underlined and the first AUG sequences in each RNA are enclosed in boxes.

Fig. 4 The *bio* promoters are compared to the tryptophan[35] and lactose[36] operon promoters of *E. coli*. All promoters are aligned by their Pribnow boxes. The wild-type *bio* promoters are dissimilar in sequence, though the *bioP98* and *bioB* promoters share extensive homology due to the imperfect palindrome. All the *bio* promoters are more closely related to the tryptophan operon or bacteriophage promoters than to the lactose operon promoter. Sequences that are similar to the recognition site of the *trpE* promoter are enclosed in boxes. In the *bioA* promoter, these 'recognition' sequences are unusually close to the Pribnow box. The base substitutions in the *bioP98* promoter are underlined. The mRNA starts (arrows) were determined by an indirect method[53]. RNA samples were divided into two aliquots and one aliquot was treated with bacterial alkaline phosphatase to remove the triphosphate at the 5′ end. Comparison of RNase Tl fingerprints of the two samples immediately identified the 5′-oligonucleotide. We cannot yet rule out initiations of leftward transcription at positions 8, 9 or 10 or of rightward transcription at position 20. It is unusual that the rightward transcript is initiated with uridine-5′-triphosphate.

bioB promoters overlap the 'palindrome,' they share considerable homology. However, these promoters are not equally utilised *in vivo*.

Operator sequences

The putative *bio* operator, like the *lac*[44], *trp*[35], *gal*[40] and phage λ (ref. 30) operators, is an imperfect palindromic sequence and suggests a symmetrical repressor interaction. The imperfect palindrome is larger than any other sequenced operator and bears no sequence resemblance to any of the other operators. The palindrome could be increased by deletion of the A-T base pair at position 8 or an insertion of an A-T base pair between positions −8 and −9.

Comparison with other control regions

Recently, considerable progress has been made in determining the DNA sequences of several regulatory regions[23–43]. Comparative studies of the overall organisation of control regions as well as the individual regulatory elements have become possible. The *bio* system incorporates some of the general features of the unidirectional operons. Like *gal*, *lac*, *trp* and λp_L, the 'palindromic' operator overlaps the promoters. In the *bio* system we find an unusual transcriptional pattern; two transcriptional units are coordinately regulated from a single control region and both code for enzymatic activities rather than there being a single operon for a regulatory factor and another for enzymatic activities. Other examples of divergent transcription are the *argECBH* cluster[45], the $\lambda p_R - p_{rm}$ system[46] and the *araCBAD* locus[47].

In both $\lambda p_R - p_{rm}$ and *ara*, the rationale for divergent transcription is to permit the modulation of autoregulation. In the $\lambda p_R - p_{rm}$ region, three operators overlap both back-to-back and overlapping promoters[46]. A low level of repressor both stimulates leftward transcription from p_{rm} to produce more repressor protein and decreases rightward transcription from p_R (ref. 14). As repressor accumulates, all the operator sites become occupied and transcription from p_{rm} is shut off. In *ara*, the *araC* gene product acts both as a repressor of its own synthesis and an activator of the arabinose catabolic operon in the presence of arabinose[47,48]. Again, the two operons are interactive, transcription of *araC* is not independent of transcription of *araBAD*[19]. Thus, in these operons, divergent transcription permits fine tuning of the primary metabolic operon and the operon coding for the autoregulated control protein. This is not the case for the *bio* cluster as none of the *bio* genes are required for the expression of remaining *bio* genes[9].

In summary, the *bio* regulatory region has been located by two independent methods. It is proposed that the *bioA* and *bioB* promoters are located face-to-face and partially overlap. Direct evidence that the promoters are in the proposed positions must come from sequence studies of individual promoter mutations or from the 5′ end sequences of the *in vivo* mRNAs because all *in vitro* binding or transcription assays are potentially subject to artefacts. It nevertheless seems unlikely that the same small DNA region that contains the site where insertion of IS*1* inactivates *in vivo* transcription of both *bioA* and *bioB*, and that possibly contains the *bioP98* and *bioO34* mutations, should coincidently contain the sites for the initiation of *in vitro* transcription. The proposed operator site contains or is entirely composed of an imperfect palindromic sequence. A new promoter may be created by the *bioP98* mutation.

Detailed descriptions of the RNA and DNA sequence determinations from positions −180 to +150 will be presented elsewhere.

We thank Drs Herbert Boyer and Howard Goodman for cloning vehicles and techniques, Dr Sidney Hayes for separated λ*biot*124 DNA strands, Dr Donald Helinski and his laboratory for advice on plasmids, Dr Arthur Landy for helpful discussions, Dr Richard Roberts for help with the restriction endonucleases, Dr Winston Salser for help with DNA sequencing and Dr Michael Smith for *FnuE*I endonulease. Special thanks to Dr Allan Campbell who made this project possible. This research was funded by grant NP-181 from the American Cancer Society and grant PCM 74-21089 from the NSF.

Preferred frequency for interstellar communications

MANY scientists believe that intelligent life is common in our Galaxy[1–6] and that electromagnetic waves are the most practical means of communication[7,8]. Even equipment of a terrestrial standard can produce communication within a distance of 100 light yr. Several searches for interstellar signals have been proposed; however, difficulty arises in the selection of technical parameters such as frequency and coding. Among these, the selection of frequency is the most important. We propose here that the 4,829.659-MHz line frequency of the $1_{11} \rightarrow 1_{10}$ rotational transition of formaldehyde is a plausible frequency.

Simple calculations show that the number of possible frequency channels is so large that a search is not realistic, and we can assume that another party wishing to communicate would also consider this unpractical. Thus we need to predict the other party's decisions, and we can rely only on the common knowledge between the two parties. This also applies to the other party, so certain discrete frequency channels can be specified.

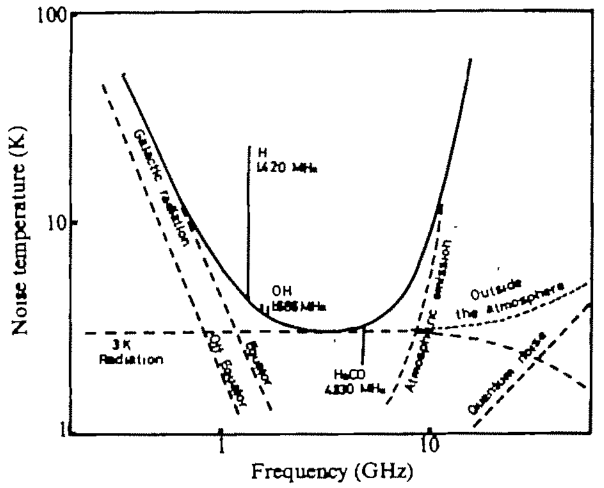

Fig. 1 The background noise temperature plotted against frequency. The solid line shows the total noise temperature on the surface of the Earth. Outside the atmosphere, the influence of atmosphere can be neglected in high frequencies and the total noise temperature is shown by the short-dashed line. The long-dashed lines show each component which sums up to form total noise emission. The absorption line at 4.83 GHz is the formaldehyde absorption band in the direction of dark clouds.

Cocconi and Morrison[7] suggested the use of neutral hydrogen line frequency of 1,420.406 MHz which was then the only known radio spectral line in the Galaxy. If transmitted at this frequency, the possibility that the signal could be detected by chance by some unknown party is higher than at other frequencies: it would help to establish 'implicit mutual agreement'.

0028–0836/78/0276—0694$01 00

The 4,829.659-MHz H_2CO line, because of the anti-maser effect, exhibits a very low excitation temperature[9]. Due to this anti-maser absorption, the background radiation temperature in the directions of dark clouds is below the 3 K background temperature. If a search is made at this frequency, we get a lower noise temperature than at any other frequency bands (the opposite is true for the hydrogen 21 cm line). Although the background noise temperature is lowered only by ~1 K, the depression itself could be interpreted as a significant marker.

A civilisation on a star which we see in front of a dark cloud must be aware of this advantage and would transmit signals at this frequency knowing that we know of the same advantage and could forecast their decision. One can specify the frequency of this absorption minimum within 5 kHz (300 m s^{-1} in Doppler shift) due to low temperature dark clouds. The absorption line is narrower than other lines, but above all, the frequency of the transmission signal can be set to the absorption minimum determined by observations and the search band is much narrower compared with other proposed bands. Properties of this frequency band as discussed above meet the requirements of the beacon signal necessary to establish the first contact. If intelligent civilisations are common throughout the Galaxy, they must have formed a community using communication and must be sending beacon signals.

There are many dark clouds, covering a substantial fraction of the sky and many stars that can be seen in front of such clouds. A characteristic of our method is that we can specify not only the frequency but also the directions to be searched.

Candidate stars in the direction of the nearest dark cloud, Coal Sack Nebula, are listed in Table 1. These are the stars of luminosity classes IV and V with the spectral types F, G, K and M in the Michigan Spectral Catalogue[10].

The controversial carbon solid–liquid–vapour triple point

THE controversy over the solid–liquid–vapour (S–L–V) triple point of carbon began in 1849 (ref. 1). Since then, investigators have developed widely differing points of view which are discussed here. Some believe the triple-point pressure is $\sim 10^5$ Pa (~1 atm), whereas others believe it is $\sim 10^7$ Pa (~100 atm). Over the past 40 yr, the 10^7 Pa view has dominated but the evidence is not entirely convincing. In the past few years, new evidence has been obtained that apparently ends the controversy at least from the standpoint of the proper order of magnitude of the pressure.

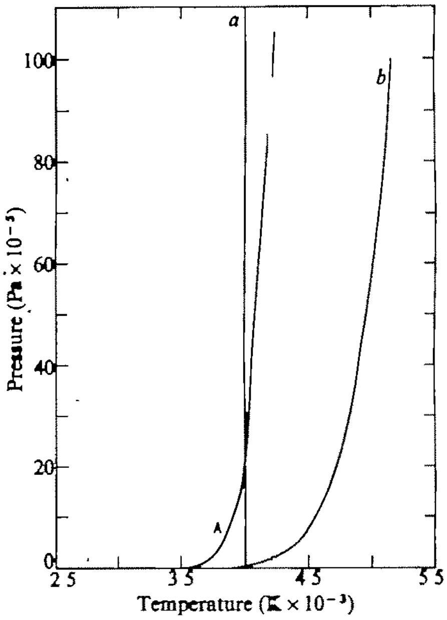

Fig. 1 Solid–liquid and solid–vapour boundaries for the low-pressure region of the carbon phase diagram. *a*, Bundy; *b*, JANAF.

In any single-component phase diagram, the S–L–V triple point is located at the intersection of the solid–liquid (S–L) and solid–vapour (S–V) boundaries. These boundaries for carbon are shown in Fig. 1. The S–L boundary was obtained by an extrapolation of Bundy's high-pressure data, and the JANAF data gives the S–V boundary[2,3]. Even though Bundy's extrapolated data could be in error by 100° or 200°, these boundaries (Fig. 1) indicate that the S–L–V triple-point pressure must be of the order of 10^5 Pa. However, the S–L–V triple point was believed to occur at $\sim 10^7$ Pa and 4,200 K, and it was considered that the JANAF calculations above ~3,000 K might be wrong. Thus, S–V boundaries, such as A in Fig. 1, were proposed, even though there was little experimental basis[4]. The question of which S–V boundary is correct can be answered by considering the results of several studies on the vapour pressure of carbon in the region of 4,000 K.

Covington, Liu and Lincoln[5] and Lundell and Dickey[6] have obtained vapour pressure data that confirmed the JANAF data in the region of 10^5–10^7 Pa. Also, Maurer *et al.*[7] obtained data at $\sim 10^4$ Pa that agreed with the JANAF curve. Data obtained several years ago indicated that graphite transforms to the more stable carbyne forms of carbon above ~2,600 K. Hence, the equilibrium S–V boundary must lie below the JANAF curve. All these data are shown in Fig. 2 in the region of the S–L–V triple point. I have recently reported[11] preliminary data on the rate of transformation of graphite into each of two of the carbyne forms[11]. These data also show that the lowest transformation temperature is ~2,600 K and supports the conclusion that the equilibrium vapour pressure of carbon must be less than the JANAF values above this temperature. These rate data show that the transformation graphite → carbyne is relatively slow up to 2,800 K (first-order rate constant of $\sim 10^{-5}$ s at 2,800 K). There is some evidence that the transformation rates increase with temperature as expected, but 2 or 3 s are required for 80–90% conversion in the region of 3,800 K. Therefore, the transformation did not have time to take place in the experiments of Covington, Liu and Lincoln because their measurement time was of the order of 1 ms or less. Hence, their data would be expected to fall on the JANAF curve because it represents the vapour pressure that graphite would have if it were the stable form above ~2,600 K. In the experiments of Lundell and Dickey, it is difficult to estimate the time required to heat and vaporise the carbon because the beam traversed through the sample at an appreciable rate. However, it seems

0028-0836/78/0276—0695$01 00

that the time available for transformation of the carbon was well below 1 s, especially at the higher power densities. Therefore, their data would be expected to fall on the JANAF curve. These five groups of data constitute a mutually consistent set that experimentally establishes the S–V curve in the region of 4,000 K and rules out the possibility of an S–V curve in Fig. 1A. With the S–V curve thus established, the only other way to get an S–L–V triple point at $\sim 10^7$ Pa would be for Bundy's data to be in error by $>1,000$ K, which is highly unlikely.

If the S–L–V triple-point pressure of carbon occurs at $\sim 10^5$ Pa, $\sim 10^5$ Pa, then it is reasonable to question the significance of the results obtained at $\sim 10^7$ Pa. The pressure reported range from 1.01 to 1.22×10^7 Pa, but most values approximate $1.01 - 1.03 \times 10^7$ Pa. Temperatures range from ~ 3,970 to 4,390 K with no tendency to cluster about a particular value. All these high-pressure results have at least two major shortcomings: (1) in all cases, it was assumed that the carbon vapour pressure equilibrated with the pressurising gas. This does not necessarily happen, and some means must be provided to show that this condition has been achieved. Therefore, the pressures are suspect as they are not really experimentally determined but essentially assumed values. (2) No spectroscopy was carried out on the radiation that arrived at the pyrometer. It must be confirmed that line or band emission is not causing spurious pyrometer readings and it must be shown that the radiating gas surrounding the specimen is not optically dense. In the laser heating experiments of Whittaker *et al.*, much spectroscopy was carried out on the solid and gas phases. It was found that the carbon gas emits only Swan radiation. If impurities are present, additional lines or bands appear in the spectrum; hence, it is important to ensure that the pyrometer uses a wavelength range that is free of this radiation. Also, the optical density of the gas was found to increase with pressure, and, at $\sim 10^6$ Pa, the effect of the optical density is no longer negligible. At 10^7 Pa, the optical density would be quite high. Hence, a pyrometer may not be able to 'see' the surface of the condensed phase at this pressure. In this case, the reported temperatures would have little meaning. Indeed, the effect of high optical density could account for the wide range of reported temperatures.

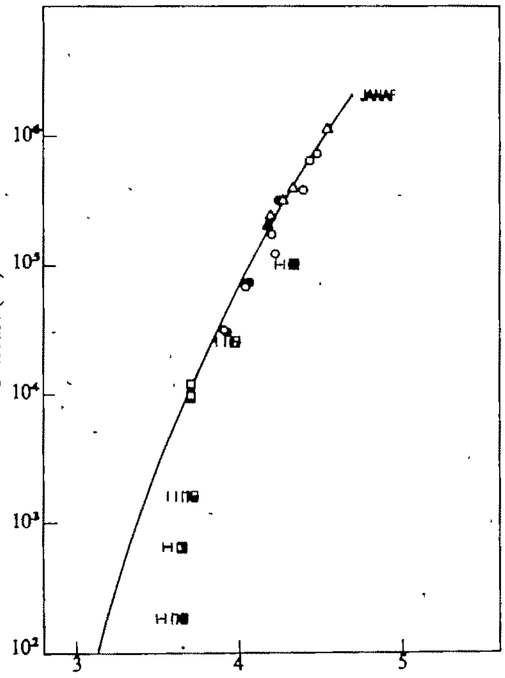

Fig. 2 Vapour-pressure data for carbon in the region of the S–L–V triple point. △, ref 6; ⊙, ref. 5; ⊡, ref. 7; |·| ( ), refs 8–10, with error bars and number of determinations shown.

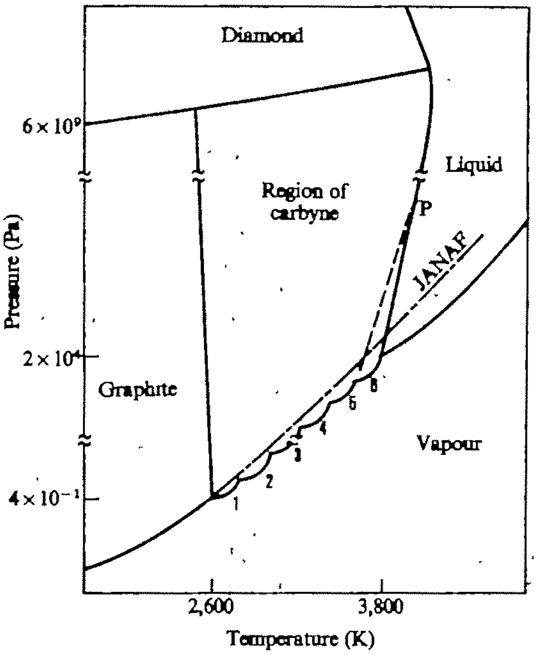

Fig. 3 Proposed carbon-phase diagram[10].

One possible reason that the high-pressure data clusters in a general region is that a solid–solid–liquid triple point could exist near 10^7 Pa at point P in the proposed phase diagram (Fig. 3)[10]. In this case, the solid phases would have to be carbyne forms of carbon. As the equipment used in the high-pressure work was not designed to study condensed-phase equilibria, the observed pressure and temperature would be some kind of average determined by the competition between the condensed-phase equilibrium and the liquid–vapour equilibrium attempting to coexist. This situation would result in a large scatter in reported temperatures and pressures because this competition would depend on the idiosyncrasies of each particular apparatus.

The uncertainties discussed here make it difficult to interpret the high-pressure results. However, the recent vapour-pressure data together with Bundy's high-pressure results, contribute to the conclusion that the S–L–V triple point of carbon occurs at a pressure of the order of 10^5 Pa, and that the reported results in the region of 10^7 Pa must refer to some other phenomenon.

A surface related component of iron metal in lunar samples?

SOLAR wind elements implanted into lunar soil grains come to rest within a few hundred angstroms, consequently high concentrations should build up in near surface locations. It has become common practice to 'identify' surface correlated species by investigating sieved soil fractions; the increased concentrations in fine grain sizes being attributed to the greater surface area. The approach used[1–4], infers a surface location for finely divided iron metal (Fe(0)) and associated hydrolysable carbon (C_{hyd}) in lunar samples. These studies, together with other evidence[5], imply solar wind induced reduction processes were involved in producing metal from ferrous iron (Fe(II)) in silicates. The experiments described here performed with a reagent ($CuCl_2/2KCl$), which should only attack exposed metal, have failed to recognise a genuine exposed surface component. We believe that some effect associated with solar wind sputtering is responsible for iron formation and we must therefore question the validity of the model on which the initial conclusions in favour of surface located metal were based.

To obtain a quantitative measure of surface located iron metal, a mild specific leaching agent was used. Although X-ray photoelectron spectroscopy (XPS)[6,7] may distinguish between Fe(II) and Fe(0) at depths <20 Å, this technique is not quantitative. Fe(0) is readily dissolved in a $CuCl_2/2KCl$ solution due to the replacement reaction[8,9]:

$$Fe^0 + Cu^{2+}(aq) \rightarrow Fe^{2+}(aq) + Cu^0$$

Two gram aliquots of tachylyte basaltic glass (Snake River, Idaho) together with 0–5 mg quantities of iron metal (high purity, British Chemical Standards) were treated with 25 ml of an aqueous solution of the reagent (13.33 g $CuCl_2 \cdot 2H_2O$, 11.66 g KCl in 250 ml doubly distilled water); filtered solutions were diluted so that iron was in the 0–1 p.p.m. range and analysed by atomic absorption to provide a calibration graph. A comparison with results obtained by acid treatment of iron turnings only, suggests that the copper reagent dissolves Fe(0) completely within the error limits of the measurement. The copper solution does not leach Fe(II) from the basaltic glass. Milligram aliquots of three suites of size differentiated glassy agglutinates separated from lunar soils 15601 and 12023 by sieving and density–magnetic methods[2,10] were treated with 2 ml quantities of reagent. After hand shaking intermittently during a two hour period or standing over night, the liquid was directly aspirated into the flame of the atomic absorption spectrometer. Figure 1 compares the measurements of the amount of Fe(0) taken into solution with the total abundance of metal (diameter <130 Å) determined by magnetic susceptibility[2,10]. With the exception of one sample of 15601 (150–250 µm fraction), the iron abundance in solution is small, close to the background or detection limits of the analytical method. There is no relationship with particle size; the single positive result could be attributed to dissolution of an iron meteorite fragment(s). The reagent is capable of dissolving Fe(0) associated with the samples since a variable quantity, up to 20% of the total, is found in solution after fresh $CuCl_2/2KCl$ solution is added and agitated by ultrasonic vibration for 15 min (only sample 12023 $M > 3.5$ is shown in Fig. 1). Even after ultrasonic treatment, the amount of Fe(0) taken into solution does not increase with decreasing particle size; if anything our limited data suggest the opposite.

We interpret the above results as follows: the vast majority of Fe(0), possibly >99% of the total, is located in sites inaccessible to the reagent and not on the very surface of the samples studied. It could be argued that metal was present in cavities, vesicles and pore spaces[11] which could not be penetrated by the liquid. The analysis of solutions obtained using ultrasonics, however, are not in keeping with such a hypothesis, as very fine fractions do not release the largest quantities of metal even after prolonged agitation. A microscopic examination of 12023 samples following ultrasonication shows that the agglutinates have been broken up; probably the iron was exposed to the reagent as a consequence. We would expect large agglutinates to be more fragile than small ones. For some reason, not yet clear, 15601 agglutinates were not disrupted by ultrasonic vibration.

Several mechanisms have been proposed for the production of lunar Fe(0) metal (for a review see refs 11 and 12). The hypotheses currently receiving the most attention involve reduction by some aspect of sputtering and by definition produce metal only at the very surface of grains. At face value, the results we have presented apparently preclude sputtering. They seem to favour a chemically based mechanism, whereby reduction is induced by meteorite impact heating, because water is formed from silicate oxygen and solar wind hydrogen atoms[13]. This latter mechanism might generate surface correlated metal which was inaccessible to the copper reagent. There is very strong evidence that a physical (sputtering) rather than a chemical reduction is involved: (1) both preferential sputtering of oxygen atoms[6] and preferential deposition of heavy elements, particularly iron[11], are possible in practice; preferential sputtering is theoretically predictable[12]: (2) XPS and Auger spectroscopy demonstrate major elements at particle surfaces are fractionated relative to their abundance measured for the interior[7,14]; and (3) silicon and oxygen at grain surfaces are depleted in light isotopes relative to these elements at greater depth[15]. Because of the apparent paradox, it is necessary to reconsider whether increased abundance of Fe(0) in fine fractions may only be interpreted as the presence of a surface related component.

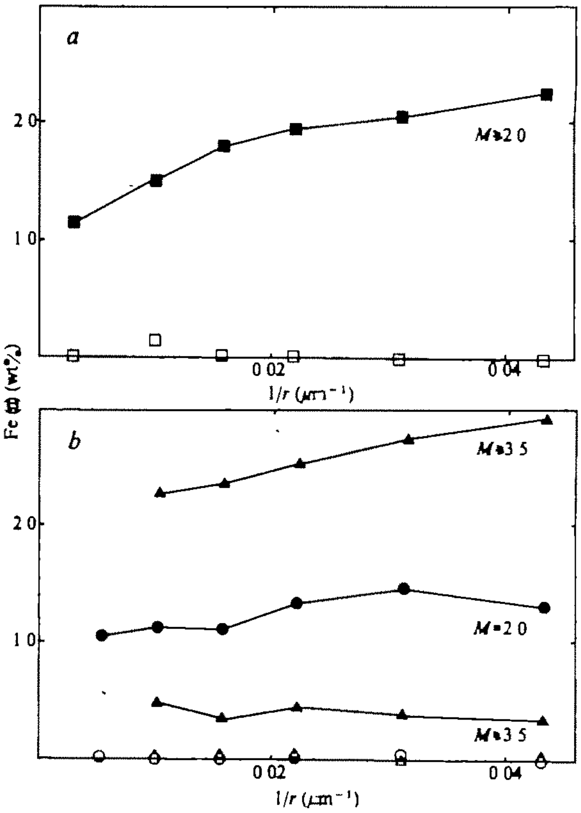

Fig. 1 Metal content of sieved fractions of glassy agglutinates from lunar soils: a, 15601; b, 12023. Closed symbols (■, ▲, ●) are for magnetic susceptibility measurements, open symbols (□, △, ○) are for $CuCl_2/KCl$ leach determinations and ▲ refers to material agitated by ultrasonic vibration whilst in the liquid reagent. The values $M = 2.0$ and $M \geq 3.5$ are the setting on the magnetic separator used to obtain the agglutinates from bulk soil; here they only identify the different fractions.

Figure 1 shows the data plotted as c against $1/r$ (where c = concentration and r = average radius of a size fraction). According to one model[16] a surface component is recognised from the slope of the line; the volume related component can be determined for particles of infinite radius from the intercept on the y axis. In this model the volume related component is assumed to be constant for all grain sizes. Such an assumption is invalid because lunar soils contain many, in fact sometimes a majority of, grains which are complex aggregates, either glassy agglutinates or microbreccias. The volume related component is due to the incorporation of a surface component into the interior of complex particles. There is no reason to suppose a volume component produced in this way would be constant for all grain sizes. On the contrary, it might be expected that fine agglutinates and breccias, which must be made up of constituent fragments with a smaller median grain size than their coarse counterparts, ought to have a larger volume related component due to the increased surface incorporated. A volume component which increases in fine fractions would be indistinguishable from a surface component on a plot of c against $1/r$. An alternative model[17] which considers $c \propto d^{-n}$ (where d is diameter) and recognises surface and volume related components from a plot of $\log c$ against $\log d$ is also incapable of distinguishing a surface from an increasing volume component.

We now contend that surface related components of Fe(0) and C_{hyd} are minimal; c against $1/r$ or $\log c$ against $\log d$ plots recognise increasing volume related components, which are a result either of a greater abundance of aggregated particles or a greater complexity within such grains in fine fractions. Some support for the latter interpretation has come from detailed analysis of progressively more magnetic agglutinates from lunar soil 12023 (ref. 10). We have pointed out[2,12,18] that genuine surface components of $Fe(0) < 130$ Å in size would be unlikely to survive in the terrestrial atmosphere and that only metal incorporated into agglutinates would be protected from oxidation. Agglutinate metal behaving as an apparent surface related component because of increases in volume concentration does not conflict with such arguments.

If model predicted surface components of Fe(0) and C_{hyd} are in fact volume components, what proportion of the apparent surface correlated solar wind hydrogen, rare gases, carbon and nitrogen can be accounted for by this effect? The answer to this question presumably will come from comparison of data from size fractions with measurements made by surface specific techniques such as ion microprobe[19,20] and nuclear reactions[21,22]. Calculations[23] and direct measurements[22] suggest maximum surface carbon concentrations are up to a factor of five less than estimates made on the basis of $1/r$ plots[24] and thus support arguments in favour of an increasing volume component.

We are not denying the existence of surface components, only questioning their magnitude; surface components must exist to be incorporated into complex grains to generate volume related components. We need better models to describe the accumulation of solar wind elements and solar wind derived species in lunar soil. Experiments using surface specific techniques to detect genuine surface components are highly desirable.

Organic ^{14}C activity in an abyssal marine sediment

ONE measure of transport rates and residence times of organic carbon within the various organic carbon pools in the ocean is to follow perturbations from the 1952–58 and 1961–62 atmospheric thermonuclear bomb tests on the natural ^{14}C activities of living, detrital and dissolved organic matter. We report here our measurement of the ^{14}C activity of the total sedimentary organic carbon (SOC) in an abyssal red clay, as no such data were available for this organic carbon pool. Ultimately, these sedimentary organic ^{14}C activities may be compared with the ^{14}C activity of the source organic material in the water column and estimates made of the magnitude of organic carbon consumption at the seawater–sediment interface. What was found, unexpectedly, was evidence for the penetration of recent organic carbon from the 4 cm mixed layer at the sediment–seawater interface down to at least 12 cm in the sedimentary column. This suggests a different and more rapid mechanism for the sedimentation of some fraction of the SOC other than direct association with clay minerals.

Photosynthetic fixation of bomb-derived $^{14}CO_2$ in the euphotic zone and its subsequent incorporation into bathypelagic marine fish and crustacea and into deep-sea particulate and dissolved organic matter has been previously studied in the north Central and North-east Pacific Ocean[1–4]. This work (Table 1) showed that the dissolved (plus colloidal) organic carbon (DOC) had 'apparent ages' of 740 yr BP at the surface to 2,570–3,470 yr BP at 2,000 m, and that the ^{14}C activity of the particulate organic carbon (POC) at 2,000 m was 10% less than its activity at the surface. These observations are indicative of slow recycling of DOC between the surface and deep waters and rapid sinking of POC (or some fraction of it) in the water column. Thus, high ^{14}C activities of SOC in the upper mixed layer and at the seawater–sediment interface would reflect this rapid sinking of POC to the sea floor coupled with its relatively slow biochemical oxidation to CO_2 by benthic populations.

The 0–30 cm sediment sections (Table 2) were sub-sampled from two box cores[5] (0.25 m² in area) taken on 10 July 1970 (core 33) at 6,040 m in the central North Pacific Gyre (30°0.9′ N, 156°12.5′ W) and on 8 June 1977 (core 638) at 5,780 m in the same area (28°34.4′ N, 155°30.3′ W). This region is part of an extensive abyssal plain situated beneath low-productivity surface waters. The sediment–seawater slurry (equivalent to a

*Ages calculated relative to the NBS oxalic acid standard activity using the Libby half-life (5,568 yr). Since pre-nuclear bomb surface seawater carbonates were 4% lower in activity ($\Delta^{14}C = -40$‰), all the ages given in this report are about 340 yr younger using this correction.

†Pacific Geosecs, Leg 1, Station 204 (H. Östlund, personal communication).

2-mm vertical section) was sucked-up from the undisturbed centre (25 cm × 26 cm area) of core 33 and sieved through a 65-μm mesh stainless-steel screen. The solid upper 3 cm of this core was then scraped into five arbitrary sections. The upper 3 cm of core 638 was sliced into 1-cm sections only as the surface of this core was slightly disturbed. The remainder of each core was sampled in 2-cm increments down to 30 cm leaving about 5 cm of sediment on the bottom. The samples were then frozen at −20 °C for subsequent analysis. All feasible precautions were taken to prevent contamination of the samples with ^{14}C or dead carbon. The analytical results and a summary of experimental procedures for each analysis are given in Table 2. The $\delta^{13}C$ values are included to show that they fall within the range of marine organic-$\delta^{13}C$ analyses (−18 to −22‰ for subtropical waters).

Sedimentation rates below the mixed layer for the clay mineral fraction of cores 33 and 638, determined by $^{230}Th/^{232}Th$ activities, were 1.0 and 1.2 mm 10^{-3} yr^{-1}, respectively (Fig. 1*a*). It is clear from this plot that the depth of the mixed layer is 8.0 ± 1 cm (core 33) and 4.0 cm ± 0.5 cm (core 638), assuming uniform mixing within the layers. The 4 cm mixed layer thickness for core 638 is corroborated by the total SOC analyses (Fig. 1*b*). If SOC is laid down at the same rate as the clay minerals, then no measurable ^{14}C activity would be expected much below the mixed layer, however, significant ^{14}C activity was found down to at least 11–13 cm in core 638 (Table 2, Fig. 2).

The ^{14}C activity in the surface slurry (0–0.2 cm) from core 33 was not significantly higher than the ^{14}C activity found at 0.2–0.4 cm, and just significantly greater than the ^{14}C activity in the 2.7–3.0-cm section (Table 2). This implies rapid mixing and/or rapid utilisation in the mixed layer of POC reaching the seawater–sediment interface. The presence of bomb-^{14}C in the mixed layers in cores 33 and 638 can be seen by calculating a hypothetical mean age of the SOC in the mixed layer[9] assuming the $\Delta^{14}C$ value of the source organic carbon before the bomb tests was 0‰ (see Table 1). This calculation is based on the thickness of the mixed layers, M (8.0 and 4.0 cm), the $^{230}Th/^{232}Th$ sedimentation rates, S (1.0 and 1.2 mm 10^{-3} yr^{-1}) and the decay constant for ^{14}C, λ (1.2449×10^{-4} yr^{-1}) where the mean age $= 1/\lambda \ln[1 + (\lambda/S)M]$. For core 33 this calculated mean age is 19,200 yr and for core 638 it is 13,200 yr (vertical dashed line, Fig. 2). When these calculated ages are compared with the experimentally determined ages (Table 2, Fig. 2), it is apparent that more bomb ^{14}C has entered the mixed layer in core 33 than in core 638. This increased input of bomb ^{14}C in the mixed layer of core 33 is also reflected by the 42% more $^{239+240}Pu$ that was found in the 0–3-cm section of core 33 than in the 0–3-cm section of core 638 (Table 2). The presence of $^{239+240}Pu$ activity in the mixed layer of both cores is evidence of the rapid sedimentation of high ^{14}C activity POC as the flux of $^{239+240}Pu$ is, in part, through association with sinking organic detritus[10].

The main feature of the organic ^{14}C activity in the sediments is the presence of measurable ^{14}C activity below the mixed layer in core 638 (Fig. 2). An 'apparent sedimentation rate' of recent SOC, calculated from the ^{14}C activities at 6, 8 and 12 cm is 1.15 cm 10^{-3} yr^{-1}, and 0.95 cm 10^{-3} yr^{-1} if calculated from the activities at 1.5, 6, 8, and 12 cm (Fig. 2). These rates are about 10 times those derived from $^{230}Th/^{232}Th$ ratios, but due to uncertainties in the ^{14}C activity determinations, the recent SOC rates could vary from 0.8 to 6 cm 10^{-3} yr^{-1}. Thus, the introduction of recent organic carbon below the mixed layer is

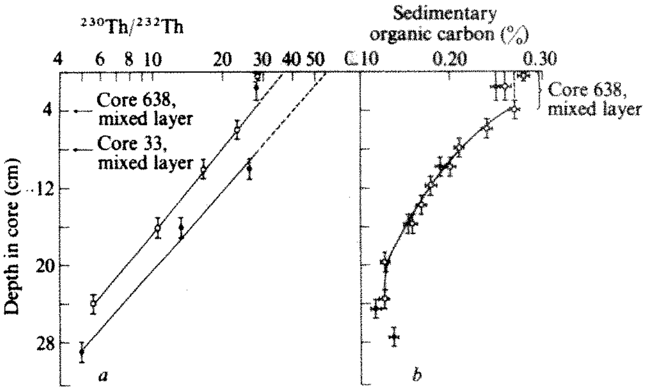

Fig. 1 *a*, $^{230}Th/^{232}Th$ ratios plotted as a function of core depth: ●, core 33; ○, core 638. Error bars denote one standard deviation. The lines are least squares fits and the depth of the mixed layers are indicated by arrows. The clay mineral sedimentation rates below the mixed layer are 1.0 mm 10^{-3} yr^{-1} for core 33 and 1.2 mm 10^{-3} yr^{-1} for core 638 where the half life of ^{230}Th is 7.52×10^4 yr. *b*, Total sedimentary organic carbon (SOC) expressed as per cent of dry weight and plotted as a function of core depth: ●, core 33; ○, core 638. Error bars denote one standard deviation. The dashed line from 0 to 4 cm is the mean of values at 0–1, 0–3 and 3–5 cm for core 638.

independent of the sedimentation rate of the clay minerals or SOC associated with them.

The mechanism or mechanisms responsible for this apparently anomalous injection of significant quantities (calculated to be 7–13% of the total SOC depending on whether the source carbon is pre-bomb, $\Delta^{14}C = 0‰$, or post-bomb, $\Delta^{14}C = +180‰$) of recent SOC into the sedimentary column below the mixed layer is not clear. One explanation is organic carbon transport by burrowing organisms such that the numbers and lengths of their excursions, and hence the organic carbon flux, decreases with depth. The long straight burrows, 10–30 cm in length, which have been observed in abyssal sediments[11] are due primarily to worms burrowing into the sediment. The worms pump in surface seawater, filter out organic matter and eventually retreat leaving organic tubules behind. This mechanism for organic carbon transport is questionable for two reasons: (1) the smooth distribution of thorium isotopes (Fig. 1*a*) do not reflect any large scale bioturbation, and (2) the number of burrows normally observed in deep sea sediments do not seem sufficiently dense[12,13] to maintain the necessary flux of recent organic carbon.

A second explanation for the injection of organic carbon into the sediments is diffusion of recent DOC into the sedimentary column from the mixed layer. This mechanism would require a negative gradient of DOC in the interstitial water and a high concentration of DOC to be continuously added to the mixed layer by relatively rapid biochemical processes (solubilisation of detrital POC, autolysis of organisms, and excretion of DOC by organisms). However, the opposite mechanism is indicated by an analysis of DOC in the interstitial water of a pelagic clay from the central equatorial Pacific[14] (10°40′ N, 147°40′ W) where the DOC concentration increased from 2.5 mg C l^{-1} at the surface to 4.8 mg C l^{-1} at 30 cm in this core. Because the amount of DOC in the interstitial waters of red clays is only 0.1–0.4% of the total SOC, unrealistically high diffusional fluxes of DOC would be required even with strong, negative DOC gradients. Thus, neither of the above mechanisms satisfactorily explains the presence of recent organic carbon 6–12 cm below the mixed layer in this pelagic red clay.

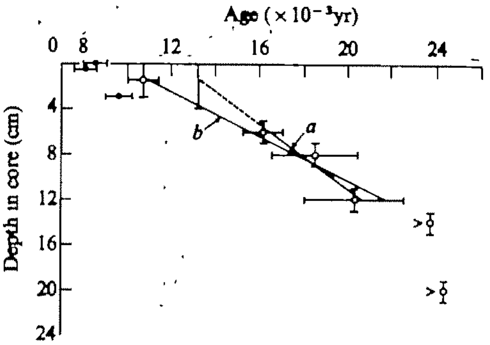

Fig. 2 The ^{14}C activity of the sedimentary organic carbon plotted as ages (yr BP) against core depth: ●, core 33; ○, core 638. Error bars denote one standard deviation (Table 2). The symbol (>) means that the ^{14}C-organic carbon activities at 13–15 and 19–21 cm were within 2σ of background and hence error bars were not applicable. The lines *a* and *b* are least squares fits for points at 1.5, 6, 8 and 12 cm; and at 6, 8 and 12 cm, respectively. The vertical dotted line from 0–4 cm represents the calculated age of the sedimentary organic carbon in the mixed layer for core 638 (see text).

There is some corroborative information on possible bioturbation below the mixed layer from $^{239+240}Pu$ analyses of two box cores collected on the 1977 cruise. These two cores were taken 1.6 and 6.4 km from core 638. The $^{239+240}Pu$ analyses (V.

Table 2 Measurements made on the sediments and sedimentary organic matter from box cores 33 and 638

The thawed sediment samples used for ^{14}C activity determinations were acidified to *p*H 3–4 with distilled 6 M HCl, and all samples were dried to constant weight at 80 °C. Thereafter, the dried sediment samples were burned at 800–900 °C for 2–3 h in a stream of prepurified oxygen. Conventional vacuum line techniques were used to obtain CO_2 of high purity necessary for gas-proportional counting. Each CO_2 sample was aged for 4 weeks before counting to ensure decay of any ^{222}Rn (3.8-d half life). The ^{14}C activity was measured using a 100 ml quartz gas counter filled to a pressure corresponding to 90 cm CO_2 at 25 °C. In these conditions, 95% of the activity of the NBS oxalic acid standard was 0.727±0.015 c.p.m. above a background of 0.815±0.012 c.p.m. A minimum of 10,000 counts was accumulated for each sample, normally over two separate counting periods. Two blanks were run; one using no sediment and the other using an oxidised portion of the original sample. No CO_2 was evolved by either procedure. The CO_2 recoveries were 70–90% based on the total SOC contents. The $\Delta^{14}C$ and $\delta^{13}C$ values and ages quoted in Table 2 have been calculated in the normal manner[6]. The $^{230}Th/^{232}Th$ (ref. 7) $^{239+240}Pu$ (ref. 8) methodologies were applied to the same non-acidified, dried sediment samples as used for the ^{14}C determinations, and the SOC contents were done using a Hewlett-Packard CHN Analyser. No differences were found in SOC between acidified and non-acidified sediment samples within the error of the method (±0.015% C), indicating that the carbonate content of the sediment was <0.03%. This was confirmed by infrared analysis of the CO_3^{2-}–CO_2 in non-acidified sub-samples.

Bowen, personal communication) showed penetration of $^{239+240}$Pu down to 12 and 14 cm in these cores. Previous measurements[15] by Bowen for two box cores taken in 1974 in the same general area showed penetration of $^{239+240}$Pu from the surface down to 5 and 8 cm in the sedimentary column.

We thank R. R. Hessler, G. D. Wilson and B. R. Burnett for providing the box cores on cruises Seventow-7 and Indopac-15 and for helpful discussions. We thank T. W. Linick and C. Hutto for assistance with ^{13}C determinations and the ^{14}C counting work, and R. J. Baldwin for analytical help. This work was supported by the US Department of Energy and the NSF.

Did emerging continents trigger metazoan evolution?

A DIVERSE fauna of trilobites, archaeocyathids, and other shelly invertebrates can be found in rocks of early Cambrian age, but in strata antedating the Cambrian such skeletonised remains are notably absent. This seemingly abrupt appearance of multicellular animals seemed illusory to Darwin[1], whose vision of evolution assumed the gradual transmutation of species over innumerable generations. His view of life necessitated a long Precambrian record of evolving Metazoa and he, therefore, attributed the apparent absence of Proterozoic fossils to the imperfection of the fossil record and the vagaries of sedimentary geology. Discoveries of the past two decades have shown the first metazoans to be less ancient than Darwin believed. It now seems that the Metazoa evolved only in the latest Precambrian (perhaps 750–650 Myr ago), and that 100–150 Myr of evolution was sufficient to delineate the various phyla in evidence at the base of the Cambrian. The question of whether emerging continents controlled the late appearance of multicellular animals on Earth is discussed here.

Hargraves' theory[2] of crustal evolution has inspired new hypotheses on metazoan origins. Hargraves believes that the primitive Earth had a thin, but continuous, sialic crust blanketed by a world ocean some 2.8 km in depth. As the Earth matured, mantle activity progressively built the sialic crust into continental masses. The thickness of these continents was controlled isostatically, the critical crustal depth being the 750 °C isotherm (the temperature at which granitic crust begins to melt). As long as the Earth's interior was hot and, consequently, the 750 °C isotherm was shallow, the continents could not become thick enough to rise above sea level. Only as the Earth cooled could continental blocks emerge from and dissect the world ocean. Hargraves sets wide limits on the timing of continental emergence. His geophysical model for terrestrial cooling predicts that continents should have appeared 1,400–900 Myr BP, while his estimate of sedimentary rock volumes through time suggests that the actual time of emergence was 900–600 Myr BP. Hargraves does, however, acknowledge that certain patterns of sedimentation are most consistent with the existence of emergent continents before 1,700 Myr BP.

Chamberlain and Marland[3] were the first to consider the biological implications of Hargraves' theory. If Hargraves is correct, they reasoned, then before the buildup of continents to within 200 m of sea level, the global sea would have been stratified. Nutrient recycling by upwelling would have been minimal, and consequently, organic productivity would have been low. Chamberlain and Marland link both increased algal productivity and metazoan evolution to the appearance of persistently emergent continents.

LaBarbera[4] has taken these arguments further and developed an explicitly hargravesian theory of metazoan origins. He argues that it was the emergence of continents in the late Precambrian that triggered the evolution of multicellular organisms. Before the end of the Proterozoic era, environments in which early invertebrate benthos could proliferate simply did not exist, except during a few transitory periods.

If we wish to accept the theories of metazoan evolution implied by Chamberlain and Marland and defined by LaBarbera, we must first examine the physical model on which they are based. Instead of judging the merits of the Hargraves' model in its entirety[5], I shall concentrate on the aspect that bears directly on the derivative biological arguments—the timing of the appearance of continental land masses. If sizeable continents with their associated implications for erosional runoff, shallow marine platform environments, and upwelling currents existed significantly before the end of the Precambrian, then it is difficult to attribute the evolution of Metazoa to their appearance. The appropriate data for the examination of this question are the preserved accumulations of Precambrian sedimentary rocks. From these strata, one can derive important information about the type, depth, and extent of depositional environments, as well as data relevant to the delineation of sediment source areas.

The Proterozoic sedimentary record of North America is relatively well known and illuminates the problem. The oldest Proterozoic sediments on this continent are those of the Huronian Supergroup exposed north of Lake Huron. This 2,300 Myr old sequence, which has an aggregate thickness of ~15,000 m near the southern limits of exposure, contains a variety of features suggestive of deposition on the margin of a large, emergent land mass: deposition on a pre-Huronian erosion surface, sedimentary structures indicative of fluvial deposition, other structures referable to tidal flat environments, clasts derived from a granitic source area to the north, and a set of characteristics (striated pavement and boulders, tillite, and dropstones) that record an episode of early Proterozoic glaciation[6–9]. Sediments of similar age and character are also known from other areas of North America: the Kaminak Basin, North-West Territories; the Chibougamau Basin, Quebec; and the Libby Creek Group of Wyoming[10].

Sedimentary rocks deposited between 2,200 and 1,800 Myr BP are common in North America, occurring in linear geosynclinal belts and as the remnants of broad platform sequences.

Goodwin[11] has shown that the geographical distribution of these deposits is consistent with the occurrence of two large, stable early Proterozoic cratons separated by a metastable cratonic area. Goodwin's continental areas are bordered on all sides (within the limits of existing outcrops) by miogeosynclinal sedimentary rocks. Within these facies, there is abundant physical evidence of shallow water sedimentation. For example, in the miogeosynclinal belt of the Coronation Geosyncline, North-West Territories one finds arkose and orthoquartzite (derived from a source located in the direction of Goodwin's hypothesised craton), oolites, mudcracks, and gypsum casts[12]. Similar features characterise the proximal facies of the CircumUngava Geosyncline in eastern Canada[13–15]. Contrary to the assertion by LaBarbera, stromatolites abound in early Proterozoic carbonate sequences. The abundance and variety of stromatolitic structures in Coronation[16] and Circum Ungava[17,18] shelf sediments, as well as in other coeval deposits (see Table 1), provide strong testimony to the wide distribution of shallow marine environments 2,000 Myr ago. These environments were not the transitory products of dynamic crustal features such as island arcs. They are thick sequences resting on stable Archean granites and gneisses. In short, it is difficult to account for the observed pattern of early Proterozoic sedimentation without postulating the existence of large emergent or periodically inundated continental masses.

The mid-Proterozoic history of North America strengthens the case for the early appearance of continents. Between 1,700 and 1,000 Myr BP, several grabens developed at various times and in various parts of the Canadian Shield[19–21]. These basins were filled with continental redbeds and basalts in a way similar to that characterising the Triassic–Jurassic rift basins of eastern North America. In the North-west Territories, one also finds evidence of a >1,500 Myr old blanket sandstone (the Thelon Formation and its equivalents)[19] that seems to be similar in nature to the Phanerozoic 'Nubian' Sandstones of Africa. Palaeocurrent analysis of this formation suggests sediment derivation from an actively eroding land area in the vicinity of Hudson Bay[11]. During this same period thick sequences of clastics and stomatolitic carbonates were accumulating on the eastern (Grenville)[22] and western (Belt/Purcell)[23] shelves of the shield. Again, a large, emergent craton seems to be fundamental to any explanation of mid-Proterozoic sedimentation patterns in North America.

The North American record is not unusual in its pattern of Proterozoic sedimentation. Indeed, data from other continents corroborate the picture of Precambrian continents inferred from North American rocks. Several episodes of epicontinental and continental sedimentation covered the Kaapvaal Craton of southern Africa during the early Proterozoic era[24]. In earliest Proterozoic times, auriferous fluvial and alluvial clastics of the Witwatersrand Supergroup accumulated in a continental basin whose area was at least 70,000 km^2 (ref. 25). Stromatolitic carbonates of the overlying Transvaal Supergroup (2,200 Myr) suggest a shallow marine platform of still greater dimensions. Eriksson and Truswell[26] have traced the Malmani Dolomite throughout an area of 210,000 km^2. (Not only is this formation widespread geographically, it is also up to 1,500 m thick.) The Transvaal sequence itself is overlain by an extensive blanket of redbeds belonging to the Waterberg Group (1,800 Myr BP)[27].

Similar patterns can be found in Australia where broad platforms and geosynclines characterise early[28–30], middle[30,31], and late Proterozoic[32,33] sedimentary sequences. Palaeogeographical maps of the USSR for the early Riphean (1,650–1,350 Myr) illustrate emergent Russian Platform and Siberian shield areas flanked by broad expanses of shallow marine platforms[34]. In South America, deltaic sediments are known from the earliest Proterozoic of Brazil[35], and 1,800–2,000 Myr old blanket sandstones are widely distributed across the Guyana Sheild[36].

From the geological evidence, it seems that the observable record of Proterozoic sedimentation does not support the thesis that continents first became emergent late in the Precambrian era. Sizeable cratonic areas have been a persistent feature of the Earth for at least the past 2,300 Myr (I do not argue here that continents emerged at this time or that they ever emerged as envisioned by Hargraves, I simply state that they were there 2,000 Myr ago). The contention that continental areas existed in the early Proterozoic does not carry with it the implication that Hargraves' graph of sediment volume against time is necessarily incorrect. The apparent increase in sediment volume indicated for the Phanerozoic could be a real phenomenon related to Phanerozoic plate movements. Geological evidence—including cross-bedded quartz arenites, stromatolites, tidal flat sequences, and shales whose geochemistry suggests prolonged subaerial weathering—indicates that emergent land masses and shallow marine environments also existed in the Archean, although the extent and longevity of such features are less well defined than they are for the Proterozoic (see refs 37–39). I cannot agree, therefore, that Metazoa arose in response to the initial appearance of land on the Earth. LaBarbera's hypothesis that the first primitive herbivores and deposit feeders evolved from a pelagic planuloid ancestor is plausible, as is his contention that the subsequent evolution of predation greatly increased the complexity of the food web and led, through increasingly specialised adaptations, to the diversification of multicellular animals. But these steps need not have been triggered by emerging continents. They could equally well have taken place in pre-existing shallow water environments.

The concept that it was the removal of some physical barrier that made metazoan evolution possible is not new. A decade ago, the Berkner–Marshall hypothesis[40] gained widespread popularity because it provided a simple set of non-biological controls over biological innovation[40]. But the physical constraints of oxygen and ozone, like those of habitat, seem to have been removed well before the first invertebrates populated the ocean floor[42].

Why then did the Metazoa evolve when they did? I believe the answers are fundamentally biological in nature, rather than physical. As hypothesised by other workers, the rapid evolution of multicellular animals at the end of the Precambrian may have resulted from a combination of biological factors including the origin of eukaryotic sexuality, the ecological consequence of cropping, and the acquisition of that most basic of metazoan characteristics, a biochemical mechanism for the functional differentiation of genetically identical cells[43–45].

Identification of ancient heat treatment in flint artefacts by ESR spectroscopy

IT is of archaeological importance to be able to determine whether or not a particular sample of flint has been subjected to heating, either intentionally or accidentally, during its utilisation by man. We report here on the use of ESR spectroscopy for the study of flint, and show that heated material can be readily identified by the appearance of a characteristic ESR signal which is absent from the unheated flint. This signal is considered to be stable over an indefinite period of time. We have also explored other implications of this technique in the examination of flint, including its possible use for dating purposes.

Worked flint is the most abundant source of evidence for human activity before the advent of pottery-making cultures, and any information which can be deduced from it regarding its technology and date of fabrication is of considerable archaeological interest. Excavations frequently produce flint which has been accidentally subjected to the action of heat in a fire, but it is now recognised that from at least the Solutrean (~17000 BC) some flint was intentionally heated to improve its working properties[1,2]. Using experimental fabrication technique[3,4] and examining artefact material[5] show that the technique of pressure retouching is facilitated in certain flint samples by controlled heat treatment of the material, and that this fact was known and exploited in antiquity. Samples thus treated can often be recognised by the greasy lustre of fractures produced after heating, but because the useful heat treatment temperature is in the region of 300 °C, well below that at which gross structural changes become apparent, it is important to have a reliable method for identifying flint which has been heated. Flint which has been heated above about 380 °C may be suitable for dating by the thermoluminescent dating method[6,7], and some dates have been obtained for archaeological samples although there are still considerable problems associated with the application of this technique to flint which are not yet resolved. Thermoluminescence (TL) has been used to determine prehistoric heat treatment of chert artefacts[8], and has proved successful for material heated within the past 10,000 yr. Caution must, however, be exercised with samples from earlier sites where the TL acquired since heating approaches the saturation value for the unheated geological material, and the method is necessarily destructive.

The technique of ESR spectroscopy has been used to assess radiation damage in geological materials[9] and has recently been applied to cave deposits and bone associated with early human activity[10], but it has not previously been used for artefacts. It is generally less sensitive than TL but can, in principle, lead to firmer identification of the radiation-induced centres.

Our results on unheated geological samples showed the presence of a very narrow readily saturated line ($g = 2.0017$, width ($\Delta H_{MS} = 1.0$ G), which we assign to trapped electrons (e_t^-). On heating to 400 °C for 15 min this signal was lost, and exposure to a 100 krad dose of ^{60}Co γ-rays at 300 K readily restored it. We conclude that qualitative study of this e_t^- signal could be a useful and complementary technique to TL in studies of flint artefacts, and we are attempting to establish quantitative links.

Most significantly, on heating, a new signal (C) ($g = 2.0035$, $\Delta H_{MS} = 3.5$ G) developed. This is characteristic of amorphous carbon[11,12]. Traces of organic matter are known to be present in flint[13], and we postulate that these pyrolyse on heating to give carbon. The paramagnetic defects responsible for the ESR signal are, as far as we know, infinitely stable at ambient temperatures. Hence the presence of a C-signal should be diagnostic of heat treatment. To test this, we studied a group of upper Palaeolithic flints (~20000 BC), two of which were thought on the basis of appearance to have been heated in antiquity. The former gave clear C-radical signals together with e_t^- features, whereas the latter gave only the e_t^- signal.

These results establish that we have discovered a well defined method of assessing the occurrence of heat treatment in archaeological flint samples. We are now initiating a quantitative study of the C-signal as a function of the firing temperature, the time of firing and the nature of the flints. Hence we hope that ESR studies can establish conclusive details of heat treatment, and may also help to establish the probable date of such treatment.

We have also detected various other ESR signals in certain flint samples, some of which are characteristic of transition metal ion impurities such as Mn(II) and Fe(III). The form of the spectra provide information about the local symmetry around these ions. By studying their response to exposure to ^{60}Co γ rays, we should be able to gauge the extent to which these impurity ions contribute to radiation effects in flint. This could be significant as their participation could greatly modify TL in such samples.

We thank Dr M. H. Newcomer for the provision of archaeological flint samples. G.V.R. thanks Ealing College of Higher Education for support for his work at the Institute of Archaeology.

Botanical evidence linking the New Zealand Maoris with New Caledonia and the New Hebrides

TRADITIONAL history of the Maoris tells of repeated voyages between Hawaiki, their mythical homeland, and Aotearoa (New Zealand), culminating in a considerable migration about AD 1350 dated by genealogies. One canoe is said to have brought seed of the karaka tree which was a useful subsidiary food source. I report here that examination of the distribution and relationships of this tree suggests New Caledonia and/or the New Hebrides as the possible Hawaiki from which this late migration originated.

The tree *Corynocarpus laevigatus* J.R. et G. Forst. is commonly seen in the North Island of New Zealand and in the warmer coastal parts of the South Island to the southerly limit of Banks Peninsula. It is well known by its Maori name *karaka*, or on Chatham Islands where it is also commonly known by the Maori name *kopi*. Over its whole range along the coastline frequent groves are explained as Maori plantings marking old villages or campsites because in pre-European times the tree was important for food. The large kernels are poisonous but became valuable and highly nutritious when steamed or baked and washed to free them from the compound karakin which causes severe convulsions and usually death if eaten[5].

Among the interesting stories of the ancient traditional history of the New Zealand race[11], there is the record that karaka berries were brought to New Zealand in the canoe Aotea, one of a group or 'fleet' supposed to have brought a large number of Maori immigrants about the year AD 1350 (ref. 3). Other Polynesian settlements had been established in New Zealand several centuries before this wave of colonisation[3,7]. Botanists, nevertheless, have described the tree as an endemic species and it is generally regarded as such today[1], although its distribution is not as widespread as might be expected had it been growing in New Zealand for millions of years.

Seed grows readily and is widely planted in gardens throughout the country. In the wild wherever plants are protected from stock which eat foliage and fruit, seedlings arise in profusion around old trees, although they do not all survive if heavily shaded. Native pigeons, *Hemiphaga novaeseelandiae*, are known to feed on ripe berries and probably void viable seeds which are protected by a hard coat, although pigeons in laboratory trials were killed by a small dose of extract of karakin or its hydrolysate[2]. Occasional seedlings which have been noted some kilometres away from coastal groves may have been established by pigeon distribution, although pigeons are feeble fliers and if they retained seed for long they risk being poisoned. Maoris also planted seed along ridges and bush routes which they traversed, and groves may be found near old settlements growing from discarded seed thrown on middens[13].

Cockayne, discussing the vegetation of New Zealand[4], describes *C. laevigatus* as a leading physionomic plant in coastal vegetation but also makes the important remark. "As Maoris were accustomed to plant this tree near their villages doubt must frequently arise as to its occurrence in certain localities not being due to this cause. Few plants spread more rapidly by means of seed so its presence in apparently primeval forest does not disprove its being absent in the primitive community." More detailed observations on the distribution of the karaka tree are necessary, but the firm impression remains from wide observation over its range that the species is absent from many places where it can grow very well, and where one would expect it to be were it truly indigenous. The distribution on the Kermadec Islands[15] seems to be sporadic as it is in New Zealand, as though the Maoris introduced it rather than took it from there, as has been suggested[3].

Hemsley[12] described another species of *Corynocarpus* from the New Hebrides as *C. similis* because it closely resembled *C. laevigatus*. A re-examination of this species has led me to the opinion that *C. similis* is in fact the same species as *C. laevigatus*. Two flowers of the holotype of *C. similis* can be matched in detail with flowers of *C. laevigatus*, especially in the structure and toothing of the staminodes which Hemsley used as a distinguishing character. Additional flowering specimens of *C. similis* collected in the New Hebrides and fresh flowering material collected on the island of Efate are all in agreement. Leaves of the New Hebridean plants have a slightly larger maximum size and are distinctly thinner, but venation, epidermis and the finely down-rolled margin correspond with New Zealand specimens. Inflorescences are also more open and lax. Such vegetative differences may warrant making the New Zealand and New Hebridean plants different varieties of the same species, but the exceedingly close relationship between the two is certain and obviously is of special interest in connection with the Maori tradition of the origin of the karaka in Hawaiki. Hemsley[12] also described a new species, *C. dissimilis*, from New Caledonia. Careful examination shows flowers and foliage of this to be so close to material of *C. laevigatus* that it is assumed to be conspecific.

It seems improbable that the natural distribution of this single species should cover the New Hebrides, New Caledonia and New Zealand, in the light of distribution of other species of the New Zealand flora and the highly endemic character of its trees. The heavy, bulky, poisonous seed sinks in water, so that recent natural distribution over such a distance seems to be ruled out. *C. similis* is known to be present on all the main New Hebrides islands and has a vernacular name on each, seeming, therefore, to be a truly endemic plant of the group: none of the vernacular names listed by Gowers[9] bears any resemblance to the Maori names karaka or kopi. The genus is unknown from Fiji and Samoa, which are both well explored botanically. One other distinct species extends from Malaysia to Queensland[14].

Some early link between the New Hebrides, New Caledonia and New Zealand is strongly suggested by this botanical evidence, for some trees are clearly very old. As they do not form annual rings age cannot be counted in the usual way. Yen[16] has written of the movement of the sweet potato, *Ipomoea batatas*, from South America to Oceania, and the survival of the Peruvian, Ecuadorian and Bolivian name kumara. Although direct evidence of the people who effected the transfer has been lost, it is generally considered that they were probably Polynesian voyagers making early contact with South Americans between AD 400 and 700. If ocean travellers had collected the karaka in a similar manner it should be present throughout Polynesia in places other than just the New Hebrides, New Caledonia and New Zealand. This distribution supports the suggestion of direct migration, from New Caledonia and/or New Hebrides to New Zealand, based on two-way voyaging which would have suggested that an otherwise perhaps unimportant food plant would be of more use in the new land.

New Zealand anthropologists today discount the story of the 'fleet'[10], but the older suggestion that this traditional history has a factual basis is still accepted by many, including myself. Although it is clear that the links of the earlier Polynesian settlers who arrived in New Zealand from about AD 900 are all with east Polynesia[3,7], the evidence of the karaka suggests that later Polynesian settlers who arrived about AD 1350 came from New Caledonia and/or the New Hebrides, which are presumed to have contained Polynesian settlements, about 600 yr ago. They are now inhabited by Melanesians, although Polynesians and Polynesian languages are found in the New Hebrides. The large area of these islands and their fine timber resources could have supported a considerable population of seafaring people. Instructions in the traditional history speak repeatedly of the necessity of steering to the east when sailing from Hawaiki to Aotea (New Zealand). The expert seamanship and navigational ability of the Polynesians, appreciated by Captain James Cook and all the early European navigators in the Pacific, have been well examined recently[6,8] and can be in little doubt, although questioned by some[10]. The fighting referred to in the traditional history, which seems to have been a main factor driving the people of the later migration out of their Hawaiki, may have been with Melanesian invaders ousting the Polynesians, who fled to New Zealand in considerable numbers taking with them such western cultural features as the rich use of curvilinear designs and the production of many kinds of weapons, which are so characteristic of the later 'classical' Maoris but are absent from the Moa-hunter period.

I thank the staff of the Botany Department, especially Dr John Dawson, for their help. Flowering specimens of *C. similis* and *C. dissimilis* were loaned by Dr Ph. Morat and of *C. similis* by M. Malo, and the Herbarium of the Royal Botanic Gardens, Kew.

Humeral morphology of the earliest apes

KNOWLEDGE of the skeletal anatomy of early hominoids has been based on various skeletal parts of fossil apes from the Miocene of East Africa and Europe. Postcranial remains from the earlier apes of the Oligocene of Egypt consisted of a single ulna, a basal phalanx and a hallucial metatarsal[1–4]. During 1977 a palaeontological expedition from the Cairo Geological Museum and Duke University recovered four new partial humeri attributable to these Egyptian apes. These specimens now provide the first evidence of humeral anatomy of Oligocene apes and permit a better assessment of primitive forelimb morphology and locomotor abilities of earliest hominoids.

All four fossils were recovered from quarries in unconsolidated channel sands of the 'Upper Fossil Wood Zone', Jebel Quatrani Formation. This formation has been radiometrically dated as >26 Myr old[5]. All four bones are undistorted but broken so that they preserve varying portions of the distal third of the humerus. Each humerus is distinctly recognisable as primate, and because of differences in absolute size they seem to represent two taxa. Two of the specimens (DPC-1026, CGM-40123) are similar in size to humeri of the extant New World howling monkey *Alouatta*. These bones are almost certainly attributable to the largest of the Egyptian Oligocene apes, *Aegyptopithecus zeuxis*. Each articulates well with the previously described ulna of this species[1]. Two other humeri (DPC-1033, DPC-1045), although similar in overall morphology to the larger fossils, are from a smaller animal the size of the bearded saki (*Chiropotes*) (Tables 1 and 2). There are two ape species smaller than *Aegyptopithecus* known from the quarries which yielded these humeri, the type species of *Aeolopithecus*, and a new undescribed species of *Propliopithecus*. It is not clear to which of these smaller species, if either, the latter two humeri are attributable.

In order to assess both their functional and their phylogenetic significance, the new fossil humeri have been compared with samples of over 30 species of living primates and a variety of nonprimate mammals using both metric and qualitative characters. Table 2 compares the Oligocene humeri with selected groups of extant species using indices which reflect the most distinctive features of the fossils.

Table 1 Characteristics of three humerus specimens of Oligocene apes

Specimen	DPC-1026	CGM-40123	DPC-1033
Biepicondylar width	34.1	—	23.4
Angular projection of medial epicondyle	8.6°	—	6.2°
Ventral articular width	24.5	22.9	17.0
Ventral trochlea width	11.5	11.3	8.2
Ventral capitulum width	12.5	11.5	8 9
Maximum capitulum depth	13.0	11.8	10.1
Olecranon fossa depth	5.5	5.6	4.3

All linear measurements are in millimetres.

In the form of the distal articular surfaces, the fossil humeri show none of the derived features found among modern cercopithecoid monkeys and lack many derived humeral features characteristic of extant hominoids. Rather, they show a more primitive mosaic of features similar to those found in Miocene fossil apes and some present-day New World monkeys. As in most primates, the capitulum is rounded rather than cylindrical, a shape which presumably permits extensive rotation of the radius about the ulna during pronation and supination. The surface of the capitulum extends well onto the inferior surface of the humerus, indicating that the early apes were capable of a considerable range of elbow extension[6]. Compared with the condition seen in cercopithecoids, the radial side of the humerus

Table 2 Comparison of Oligocene humeri with extract species

	Capitulum depth	Trochlea width	Medial epicondyle		Olecranon depth
Species	Articular (Index *A*)	Capitulum (*B*)	Articular (*C*)	Angular projection of medial (*D*)	Articular (*E*)
Chiropotes satanas (2)	0.614	0.614	0.271	44.0°	0.307
Alouatta sp. (7)	0.579	0.809	0.365	20.4°	0.196
Macaca fascicularis (7)	0.825	0.642	0.258	44.1°	0.392
Cercopithecus aethiops (7)	0.848	0.648	0.256	50.1°	0.422
Cercopithecus mitis (6)	0.789	0.661	0.288	42.6°	0.352
Presbytis obscura (3)	0.710	0.774	0.212	37.0°	0.373
Hylobates sp. (7)	0.692	0.868	0.295	6.0°	0.304
Pan troglodytes (5)	0.623	0.946	0.400	15.8°	0.346
Dendropithecus macinnesi (1)	0.575	0.920	0.342	0°	0.311
Pliopithecus vindobonensis (1)	0.524	0.842	0.314	0°	0.253
DPC-1026	0.530	0.920	0.351	23.0°	0.224
CGM-40123	0.515	0.983	—	—	0.245
DPC-1033	0.594	0.921	0.364	24.0°	0.252

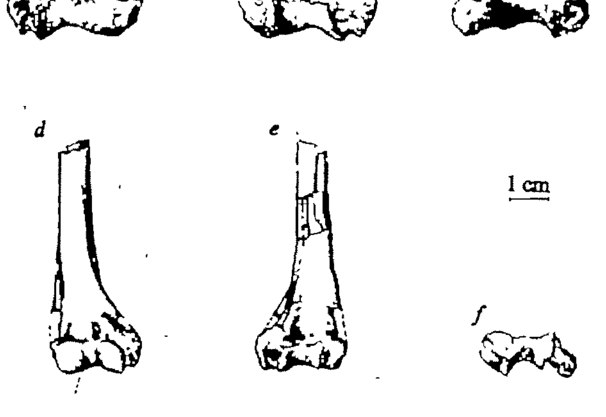
Values of the indices are given as means.
Figures in parentheses represent the number of specimens measured.

is relatively shallow in the new fossils as in New World monkeys and other fossil hominoids (Table 2, index *A*).

Medially, a low ridge separates the capitulum from the trochlea. In these Oligocene apes, this ridge is much less marked than that found among living hominoids or in Miocene *Dryopithecus africanus*; it is more comparable in shape to that of the Miocene ape *Pliopithecus* or of larger cebids such as *Alouatta*. These humeri show the relatively broad trochlea found among all other extant and fossil hominoids. This feature separates them quite clearly from cercopithecoid monkeys (Table 2, index *B*). Since a broad trochlea is also found among many prosimians, as well as these Fayum specimens, its presence among modern apes is almost certainly a retention of a primitive condition.

The Oligocene humeri lack the distinctive spool-shaped trochlea with pronounced lateral and medial margins that characterises extant apes and the Miocene fossil ape *D. africanus*. This spool-like shape, Jenkins has argued, is biomechanically adapted for maximising elbow stability through an extensive range of flexion and extension as well as in pronation and supination[7]. Even so, these fossils do not possess a narrow trochlea with pronounced anteromedial and posterolateral borders such as is characteristic of cercopithecoid monkeys (and many other pronograde quadrupedal mammals)[7]. The broad relatively shallow trochlea of Fayum apes, with its slightly developed anteromedial lip, is more comparable to that found among the more generalised arboreal quadrupeds such as the large cebids *Alouatta* or *Chiropotes*. In these New World monkeys the elbow is frequently flexed and the forearm semipronated during quadrupedal locomotion[8].

Fig. 1 Anterior (*a*), posterior (*b*), and distal (*c*) views of the left humerus of *Aegyptopithecus zeuxis* (DPC-1026) Anterior (*d*), posterior (*e*), and distal (*f*) views of the right humerus of a smaller hominoid (DPC-1033).



In the Fayum ape humeri, there is a large medial epicondyle which projects slightly posteriorly (Table 2, *C*, *D*). Among extant apes and many prosimians this process is large and projects directly medially. Inward projection of the medial epicondyle increases the medial rotatory torques which the digital and carpal flexors, as well as pronators, exert about the radio-humeral and ulnar-humero joints[7]. Amongst most Old World monkeys the medial epicondyle projects more posteriorly than medially as an adaptation for enhancing the actions of the pronators and flexor muscles when the elbow is already pronated as in pronograde quadrupedalism. The condition found among the Fayum apes is similar to that occurring in the larger arboreal quadrupedal cebids such as *Alouatta* or *Lagothrix* and represents a biomechanically intermediate condition between that of Old World apes and of cercopithecoid monkeys. On the dorsal surface of the medial epicondyle is a pronounced dorsal epitrochlear fossa similar to that seen in *Alouatta* and *Apidium*[3].

As in most extant prosimians and cebids, the olecranon fossa of Oligocene apes is quite shallow (Table 2, index *B*). In pronograde quadrupeds and knuckle-walking apes the olecranon fossa is deep. In function, a shallow olecranon fossa primarily appears to reflect the reduced posterolateral lip on the trochlea, and hence a reduced need for ulnar-humero stability during full extension of the elbow[7].

Although only one specimen preserves more than the most distal part of the humeral shaft, all four humeri show an entepicondylar foramen. This foramen, which transmits the median nerve and brachial artery from the dorsomedial surface of the arm to the cubital fossa, is characteristic of most prosimians (except lorises) and many cebids. Among catarrhines it is known only in the parapithecid genus *Apidium*[3], the Miocene hominoid *Pliopithecus*[9] and as a rare variation in other genera including *Homo*. Its occurrence in the Fayum hominoids confirms that its presence is the primitive condition for both higher primates and hominoids.

In all four humeri, there are indications of a prominent brachialis flange similar to that found among extant and fossil hominoids, as well as in medium-sized cebids and many climbing mammals. This flange is greatly reduced in Old World monkeys.

Few regions of the skeleton are more diagnostic for differentiating living monkeys and apes than the elbow region. The specimens described here provide new and unique palaeontological evidence about the morphology of this region in the earliest apes, that can be used to distinguish primitive from derived morphological conditions in living Old World higher primates. The new fossils indicate that a large medial epicondyle, relatively broad trochlea, and a pronounced brachialis flange, all found in Fayum apes, in *Apidium*, in many platyrrhines and prosimians as well as extant hominoids are primitive characters. The development of the distinctive spool-shaped trochlea with a strong ridge delineating its lateral border is a derived condition unique to extant hominoids. Such features of present day Old World monkeys as their relatively narrow trochlea with pronounced anteromedial and posterolateral lips, and relatively short, posteriorly-directed medial epicondyle are absent among the Fayum apes and parapithecids and represent derived conditions for cercopithecoids.

Thus, the new fossil evidence indicates that relative to the earliest known catarrhines, both modern apes and modern cercopithecoids show derived morphologies in the elbow region. To characterise early fossil hominoids as 'monkey-like' or 'ape-like' is to pose a false dichotomy. Rather, what can be seen in the humeral anatomy of the Fayum hominoids (as well as in many other aspects of the skeleton and cranium of these animals) is a distinct and more primitive morphology comparable to that found among the third group of living higher primates, the New World monkeys. Functionally, both the ulna[1,3,10] and humerus indicate that *Aegyptopithecus* was a largely quadrupedal, arboreal animal and that the best models for locomotor behaviour of early hominoids are neither the extant apes nor the extant cercopithecoid monkeys. Instead, closest resemblances are with the larger arboreal quadrupeds among platyrrhines, in particular the howler monkey *Alouatta*, which seems to demonstrate today a forelimb morphology similar to that exhibited by Oligocene apes.

Induction of monozygotic twinning in the mouse

VINCRISTINE SULPHATE (Oncovin, Lilly) is a drug commonly used in the chemotherapy of acute leukaemias in children, lymphomas and certain other malignant conditions. We describe here experiments investigating the teratogenicity of this drug during the early stages of embryogenesis in the mouse. We report that a low incidence of gross anomalies was observed in fetuses on days 10 and 12 of gestation when pregnant females were treated with a single dose of this agent on the sixth, seventh or eighth day of gestation. However, contrary to expectation, a high proportion of litters from females treated on the seventh and eighth day of gestation contained at least one set of monozygotic twins. In this respect the present study is unique in that an experimental method of inducing a low but significant incidence of identical twinning in a mammal is reported. Furthermore, this work provides direct evidence regarding the comparatively late stage of embryonic development when identical twin formation may be induced in the mouse, as the most advanced stage at which twinning could be induced with vincristine was at the early headfold stage. However, the highest incidence of monozygotic twinning was obtained when pregnant females were treated on the morning of the seventh day of gestation, when embryos would be expected to be at the advanced egg-cylinder stage. It was in this latter group that a single conjoined twin of the janiceps type (cephalothoracopagus) was obtained. The possible aetiology of monozygotic and conjoined twin formation is briefly discussed here in the light of these experimental findings.

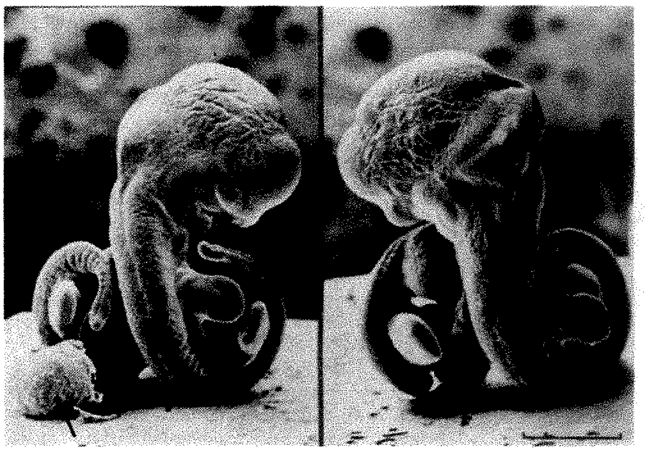

Fig. 1 Scanning electron micrographs showing two views of conjoined twin isolated on the twelfth day from a female injected with vincristine sulphate on the seventh day of gestation. A single head and thorax and two complete vertebral columns may be seen. A small round mass of tissue (arrowed) was attached to the umbilical region of one of the fetuses by a cord containing blood vessels. Scale bar, 1 mm.

Female mice, 6–8-week old virgin CFLP (Anglia), were mated with males of the same strain, and isolated on the morning of finding a vaginal plug (designated the first day of pregnancy). Females were injected intraperitoneally with 0.3 mg per kg vincristine sulphate in 0.2 ml normal saline on the morning of the sixth, seventh or eighth day of gestation. Controls were injected with a similar volume of normal saline. Autopsies were carried out on either the tenth or twelfth day of gestation. The uterine contents were examined, and the number and location of resorption sites and normal and abnormal fetuses recorded (Table 1).

In the only anomalous fetuses encountered, the region overlying the fourth ventricle was apparently collapsed, giving this region of the hindbrain an abnormally flattened appearance. These fetuses were otherwise apparently quite normal and healthy at the time of autopsy. It is not immediately clear whether the neural tissue in the hindbrain region of this comparatively small population of fetuses would have developed into, for example, an encephalocele which would have been recognisable at a later stage of gestation. It is also unclear whether these fetuses would have survived to term or into the early post-natal period. A higher incidence of fetuses with abnormal heads of this type was observed in the population of fetuses isolated from females treated on the seventh day (6.2%), compared with those isolated from females treated on

0028-0836/78/0276—0707$01.00

Table 1 Incidence of resorptions, normal and abnormal fetuses and monozygotic twins in female mice treated with vincristine

Treatment	Day of injection	Day of autopsy	Total females examined	Implantation sites Living fetuses	Resorptions	Abnormal heads	Sets of twins
Vincristine	6	10	3	39	1	1	0
	7	10	5*	64	1	5	3
	7	12	4	48	3	2	1 (conjoined)
	8	10	4	52	1	1	1
	8	12	2	25	1	1	0
Saline	6	10	3	37	1	0	0
	7	10	4	51	2	0	0
	8	10	3	38	0	0	0

Female mice were injected with vincristine sulphate or saline (controls) on the sixth, seventh or eighth day of gestation.
* An additional two litters contained only resorbed embryos.

the sixth (2.6%) and eighth (2.6%) day of gestation. This low incidence of easily recognisable neural tube pathology is of interest in the light of earlier observations of Joneja and Ungthavorn[1], who investigated the effect of an intraperitoneal injection of this agent in mice on the ninth day of pregnancy. In addition to an increase in the incidence of resorptions, these workers observed that out of 77 fetuses examined at term 5.2%, 11.7% and 6.5%, respectively, were either microcephalic, exencephalic, or had an encephalocele. This difference may be related to the strain of mice used, or more probably to the later time of administration of this teratogen. Similar central nervous system anomalies have also been reported when hamsters were injected with this agent on the eighth day of gestation[2].

Another observation that seemed to be related to the time of exposure of pregnant females to this agent in the present series was the incidence of monozygotic twins. Four sets of twins, one pair of which was conjoined, were observed when females were treated on the seventh day of pregnancy. Of the five females autopsied on the tenth day, three each had one set of twins, and a single pair of conjoined twins (Fig. 1) was isolated from one out of four females autopsied on the twelfth day of gestation. One additional set of twins was obtained from a female treated on the eighth day. At least three of the twins shared a common amniotic cavity. No twins were observed in the fetuses isolated from females treated on the sixth day of gestation. Apart from the conjoined twins all the other twin fetuses seemed to be morphologically normal.

The main interest in the present study lies in the experimental production of monozygotic twinning in the mouse, as the normal incidence in this and most other mammalian species is thought to be extremely low[3,4]. In fact, polyembryony is extremely rare and only thought to occur regularly in certain species of armadillo[5]. It is generally thought that monozygotic twins probably result from the fission of a single embryonic axis shortly after the blastocyst stage has been reached, most probably during the early post-implantation period[6,7]. It is therefore interesting that the period of embryogenesis that was most susceptible to the twinning stimulus provided by vincristine in the present study was from the advanced egg-cylinder stage to the early headfold stage of development, and it is at this latter stage that mouse embryos have a distinct head process and primitive streak[8]. Rarely, incomplete separation of these embryonic axes occurs, and results in the formation of conjoined twins. This seems the simplest explanation for the isolated examples of conjoined twins reported in this and in earlier studies in which pregnant hamsters[4,9], rabbits[10] and rats[11] were treated with teratogens, and as spontaneous occurrences in other species.

The remarkably few reports in the literature in which monozygotic and conjoined twins have been recorded as spontaneous events and following treatment of pregnant animals with teratogens seems to indicate that twins of these types were previously encountered only as isolated occurrences, unlike the present study, where they appeared to be a definite response to the vincristine treatment.

The present experimental approach thus allows for the first time detailed examination of the early stages in the development of monozygotic twins, at precise intervals after the twinning stimulus has been given. Although the exact nature of the twinning stimulus evoked by vincristine remains to be established, it should now be possible to investigate monozygotic twinning in relatively controlled conditions.

We thank J. F. Crane for photographic assistance. The work was supported by a grant from the Ch'hia Tsio Project.

Plasmid-induced loss of virulence in *Vibrio cholerae*

WE have previously reported that pathogenicity of *Vibrio cholerae* was suppressed by introducing P or V plasmids and that this effect was due to decreased toxin production[1]. This work has been extended to show that cells harbouring both P and V plasmids become attenuated and do not cause experimental cholera. Such attenuated strains are attractive candidates for live oral vaccines if it can be shown that the immunogenicity of plasmid-harbouring strains is not altered and that they remain stable. We provide here convincing evidence that the cells are not cured of their plasmids *in vitro* or *in vivo* and do not lose their immunogenic potential.

Strain KB9 served as the parent virulent strain. P and V plasmids were introduced in KB9; two strains, designated as KB9:PV and CD24, were isolated, apparently different in one respect—that P is not expressed in CD24. This is not surprising because P is often repressed by V (ref. 2). Strain 569B is a comparatively poor pathogen *in vivo* but produces significant amounts of toxin *in vitro*. CD23 was derived from 569B and characterised as having P and V plasmids. KB92 (Ogawa) and KB93 (Inaba) were virulent challenge strains. The properties of strain KB9, and the technique of introducing P and V plasmids, characterisation of plasmids, growth of vibrios, media and buffer have been described in our previous report[1].

The pathogenicity of vibrio strains was examined in the ileal loop of adult rabbits[3] and intra-intestinal infection of vibrios in infant rabbits[4]. 1–2 × 10^9 cells of KB9:PV and CD24 in 1 ml brain–heart infusion broth (Difco) were injected separately into the ileal loops of rabbits and the open intestine of infant rabbits. Neither diarrhoea nor death was recorded in the infant rabbits up to 48 h and ileal loops of the adult rabbits were without any accumulation of diarrhoeal fluid. KB9, on the other hand, caused death of the infant rabbits with 10^5–10^6 organisms and ileal loops were full of fluid. For each strain, eight infant rabbits and an equal number of adult rabbits were used. LD$_{50}$ values of these strains were estimated in Swiss mice[1] and found to be 9, 10^6 and 10^7 organisms for KB9, KB9:PV and CD24, respectively. These data suggest that plasmid-bearing cells of *V. cholerae* behave as attenuated strains.

As 569B released significant amounts of toxin in Syncase minimal medium[1], CD23 was grown in similar conditions. Assay of the toxin in the culture filtrate of CD23 gave negative results. This is consistent with our earlier observation[1] that P and V plasmids interfered with the synthesis or release of toxin.

PV strains underwent two successive passages in rabbit intestine. The loss of plasmids was never detected. These strains were subcultured several times in broth, exposed to acriflavine and sodium dodecyl sulphate, and maintained at 37 °C in broth for several weeks. Individual colonies were tested but none were found to have lost plasmids. A large number of agents which cure *Escherichia coli* of plasmids could not eliminate the sex factor P in *V. cholerae*[5]. In addition, we have evidence that when plasmids are transferred from one cell to another in conjugal mating, a copy is always left behind in the donor. Unlike *E. coli*[6], P^+ or V^+ donors remain P^+ and V^+ after mating. The experiment used was as follows: the donor was P^+, Str^s, and the recipient was a Str^R, *ile*$^-$ *val*$^-$ *arg*$^-$ *his*$^-$strain. After bacterial mating[7], the mixture was plated on minimal glucose salt medium to score the donor population, and on media supplemented with amino acids and streptomycin to score the recipient. Individual colonies were tested and it was found that all the colonies of the donor strain were P^+ and among the recipients >60% were P^+. A similar result was obtained with a V^+ donor; however, the efficiency of transfer of the V plasmid was very low. These results strongly suggest that plasmids are very stable in *V. cholerae*.

Immunogenicity was examined by immunising rabbits subcutaneously with KB9:PV and CD24. Table 1 indicates a good correlation between protection to challenge and vibriocidal antibodies in the serum. Both strains conferred good protection in Pittman and Feeley's mouse protection test[8], particularly against homologous challenge strains.

Table 1 Protective immunity and serum vibriocidal antibody titre in rabbits immunised with kB9·PV and CD24

Vaccine	Challenge strains	% Immunity to challenge	Vibriocidal titre (mean)
KB9:PV	KB92	74	3 × 10^5
	KB93	100	9 × 10^4
CD24	KB92	81	1 × 10^5
	KB93	77	8 × 10^4
Control	KB92	0	<50
	KB93	0	<50

Swiss albino rabbits weighting 1–1.2 kg were used at the time of immunisation. KB9:PV and CD24 were grown in brain–heart infusion broth and 2 × 1 ml of live culture (1–2 × 10^9 ml^{-1}) was administered subcutaneously to each rabbit at 21-d intervals. Groups of 8–10 rabbits were immunised. They were challenged on the 35th day after the second dose of vaccine and starved for 48 h before challenge. Immunity to challenge was assessed in ligated ileal loops[3] and expressed as reported previously[10]. Serum vibriocidal titres were determined according to Finkelstein[11] on serum samples collected 1 d before challenge.

Thus, we propose that plasmid-bearing strains like KB9:PV and CD24 may be used as live oral vaccines. These strains possess several other features of a vaccine strain[9] and these will be reported elsewhere.

We thank Dr Nitya Nand for facilities and interest.

Accessory cell requirement for anti-IgM-induced proliferation of B lymphocytes

THE nature of the signals which B lymphocytes must receive so as to proliferate and differentiate are not yet completely understood. It is likely that B cells with different triggering requirements exist[1,2], and that B-cell proliferation and B-cell differentiation require separate signals[3–6]. Because of this heterogeneity in signalling, it has been difficult to define precisely what is necessary to induce the expansion and differentiation of a particular B-cell clone after its exposure to antigen. It has been suggested that direct antigen binding to specific membrane immunoglobulin initiates at least one of the necessary activation signals[7–9]. Further activation signals may come from T cells and/or macrophages[7–9]. We have been studying the nature of the stimuli required for the induction of B-cell proliferation. We report here that using soluble goat anti-mouse IgM as a surface Ig cross-linking agent, we have confirmed that interactions with surface Ig can induce the proliferation of at least a subset of mouse B cells[10–12]. In addition, we have found a requirement for radioresistant phagocytic adherent cells in the polyclonal stimulation of B cells by this antibody.

Figure 1 shows the goat anti-IgM-induced proliferation of CBA/Tufts spleen cells. Optimal stimulation of 5 × 10^5 lymphocytes was consistently seen with 1–5 μg of MOPC-104E affinity column-purified goat anti-MOPC-104E (μ,λ) and TEPC-183 (μ,κ). Although 10–50 μg of normal goat Ig per culture induced a slight amount of proliferation, the stimulation was less than twofold above background. This is in contrast to the 13-fold stimulation seen with 1.25 μg of goat anti-IgM.

Purified μ,λ (MOPC-104E) or μ,κ (TEPC-183) myeloma proteins were equally effective in abrogating the proliferative response induced by the optimal dose of goat anti-IgM[13]. As little as 0.5 μg per culture of MOPC-104E or TEPC-183 completely inhibited anti-IgM-induced, but not lipopolysaccharide (LPS)-induced proliferation. Up to 4 μg per culture of

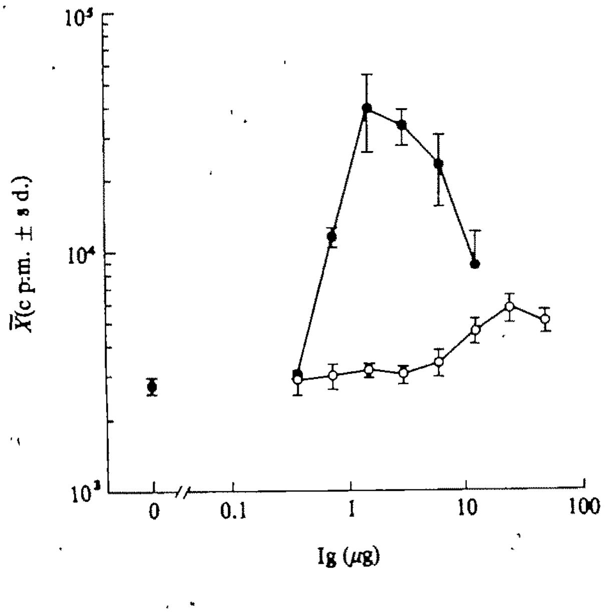
In expt 1, normal CBA/Tufts spleen cells were depleted of macrophages (M) by 2-h adherence to plastic Petri dishes in the presence of 20% fetal calf serum (FCS) and 2 subsequent passages of nonadherent cells over Sephadex G10 columns[15] prewashed with warm RPMI-1640 + 20% FCS. Macrophage-depleted cells contained less than 1% neutral red-positive, latex-positive cells. Adherent normal peritoneal cells were obtained by peritoneal lavage and 3-h adherence to plastic Petri dishes. Adherent cells removed in 1:5,000 EDTA–phosphate-buffered saline with a rubber policeman were 70% neutral red-positive, latex-positive. Adherent cells were irradiated with 1,200 rads. 5×10^3 Macrophages were added to cultures of 5×10^5 macrophage-depleted cells. A peak stimulatory dose of 2.5 μg goat anti-IgM, a dose of 0.5 μg *Escherichia coli* K235 LPS, a dose of 0.25 μg Con A or medium only was added to each culture. ^{3}H-thymidine incorporation is expressed as Δ = (experimental minus control) and as stimulation index = (experimental/control). In expt 2, normal spleen cells were incubated with 2.5 μg goat anti-IgM, 0.5 μg K235 LPS, 0.25 μg Con A, or medium. 50 μg silica (particle diameter <5 μm) was added to one series of cultures.

purified γ,κ (MOPC-21) myeloma protein failed to affect the response[13]. Hence, the proliferative response induced by the affinity-purified antibody was apparently due to anti-μ activity and not to any anti-λ or anti-idiotype activity in the preparation.

The spleen cell proliferation induced by anti-IgM seems to be a T-independent phenomenon. Spleen cells from nude mice and spleen cells depleted of T cells by T cell-specific cytotoxic antisera + complement show intact anti-IgM-induced proliferative responses[14] (our unpublished results).

We investigated the requirement for accessory macrophages in this B-cell activation system. Adherent cells were removed from preparations of nucleated spleen cells by 2-h adherence to plastic and two sequential passages through Sephadex G10 columns. Such depleted cells were poor responders to goat anti-IgM (Table 1, expt 1). The addition of irradiated adherent cells from normal peritoneum restored the B-cell response to that seen with normal spleen cell suspensions.

Fig. 1 Stimulation of CBA/Tufts spleen cells with goat anti-IgM. Various concentrations of MOPC-104E column-purified goat anti-(MOPC-104E, TEPC-183 (●) or normal goat Ig (○) were added to 5×10^5 spleen cells in triplicate flat-bottomed microculture wells to give a total volume in each well of 200 μl. Cultures were maintained in RPMI-1640 + 5% heat-inactivated FCS, with 100 U ml^{-1} penicillin, 100 μg ml^{-1} streptomycin, 20 mM HEPES (Sigma) and 2 mM glutamine. After 48 h of culture at 37 °C in a humidified, 5% CO$_2$ incubator, 1 μCi of [methyl-^{3}H]thymidine (6.7 Ci mmol^{-1}, NEN) was added to each culture. After 24 h, cells were collected and the ^{3}H-thymidine incorporation was measured. The means of triplicate cultures ± standard deviations were calculated for experimental and control cultures.



Further evidence that macrophages are ancillary cells for anti-IgM-induced proliferation was obtained from experiments in which silica, a selective toxic agent for phagocytic cells[16], was added to cultures. Silica, 50 μg, significantly depressed the spleen cell response to anti-IgM without affecting the response to LPS, another polyclonal B-cell activator (Table 1, expt 2).

The response to LPS was also unaffected by adherent cell depletion (Table 1, expt 1). In fact, the addition of adherent peritoneal cells to depleted cell cultures suppressed the LPS response. These characteristics of B-cell LPS responses have been previously noted[17,18].

Unlike the response to LPS, the B-cell proliferative response to the mitogen dextran sulphate has been shown to be macrophage-dependent[17]. Whether the apparent macrophage independence of the LPS response, in contrast to the dextran sulphate and anti-IgM responses, is a consequence of the unique activating properties of the LPS molecule[19,20] or a reflection of subsets of B cells with different macrophage requirements for activation is not yet known.

Our macrophage depletion techniques failed to decrease the macrophage-dependent T-cell response to concanavalin A (Con A)[21] to the same extent as the B-cell response to anti-IgM (Table 1). This differential sensitivity to macrophage depletion may reflect differences in the amount of macrophage help required for the stimulation of diverse lymphocyte populations or may reflect a heterogeneity in ancillary macrophage populations[22,23].

Our results suggest that, in the presence of macrophages, binding of molecules to surface IgM can activate certain B cells to proliferate. The precise role of the macrophage in this system is not yet clear. Macrophages may contribute secondary signals needed to push B cells further into the cell cycle. Alternatively, they may promote the viability of the B-cell population stimulated by anti-IgM, or they may present anti-IgM to B cells in an insoluble array. We feel the latter possibility is unlikely because: (1) anti-IgM-pulsed and washed macrophages are unable to stimulate macrophage-depleted lymphocytes in the absence of re-added soluble anti-IgM (unpublished); (2) Sieckmann *et al.* have shown that Fab$_2$, which is incapable of Fc-receptor binding to macrophages[24], and whole Ig preparations of goat anti-IgM are equally stimulatory for mouse cells[10]; and (3) 2-mercaptoethanol added to cultures can overcome the effects of macrophage depletion[13]. Whether 2-mercaptoethanol potentiates the effect of residual macrophages in adherent cell-depleted cultures or substitutes for macrophage function in the stimulation of anti-IgM responsive B cells is not known.

The population of B cells which responds to anti-IgM is thus far analogous to the population which responds to most thymus-independent antigens and the population which produces colonies in *in vitro* soft agar cultures. All these functional populations have been found to be reduced or absent in CBA/N mice and to require macrophages, but not T cells, for their activation[25-28].

This work was supported by NCI grants CA 21348 and CA 16172. P.M. holds a postdoctoral fellowship from the NSF. LPS was from Dr Floyd McIntire, the silica from Dr Jim Murray, and the goat anti-(MOPC-104E, TEPC-183) from Dr David Wilson Dresser.

Occurrence of Ia antigens on tissues of non-lymphoid origin

UNLIKE the classical transplantation antigens, called HLA-A,B,C in man and H-2K,D in mouse, the HLA-DR (Ia) antigens have a restricted tissue distribution[1]. Primarily cells belonging to the immune system express Ia antigens whose only known biological role is to participate in cell-to-cell cooperation events involving lymphocytes and macrophages[2-4]. However, cells of the immune system do not only interact among themselves but they also associate physically with other types of cells like epithelial cells of the intestine and the lactating mammary gland[5] and with reticuloepithelial cells of the thymus[6]. The possibility that all such interactions are under Ia antigen control is raised by indirect immunofluorescence analyses which show that Ia antigens are expressed on a great variety of epithelia. We report here our examination of several cryostat sections of guinea pig tissues for the presence of Ia antigens by indirect immunofluorescence. To obtain staining patterns that were reproducible and significantly different from the controls it proved necessary to use immunosorbent-purified heteroantibodies (see legend to Fig. 1 for description of the antibodies).

The specificity of the isolated antibodies was tested in indirect immunoprecipitations[7] of radioactive cell membrane glycoproteins[8]. SDS–polyacrylamide gel electrophoresis[9] of precipitated molecules derived from guinea pig splenocytes, intestine epithelial cells, salivary gland epithelial cells and Kupffer cells revealed the occurrence of Ia antigen-like proteins[10] on all four cell types (Fig. 1). The high specificity of the antibodies was ascertained by the absence on the gels of material distinct from the Ia-antigen subunits.

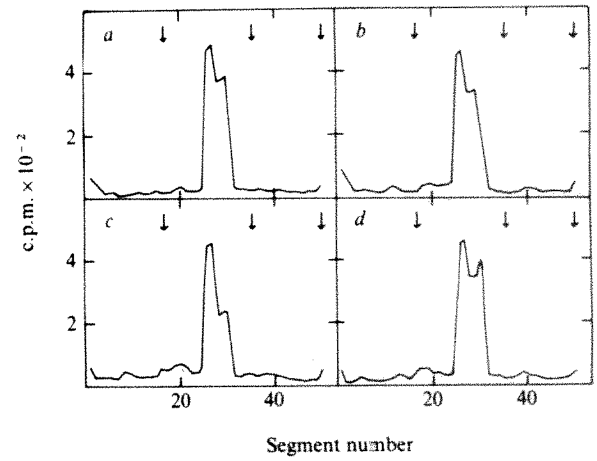

Fig. 1 SDS–polyacrylamide gel electrophoresis of ^{3}H-labelled cell surface glycoproteins indirectly immunoprecipitated with immunosorbent purified antibodies raised against HLA-DR antigens. Single cell suspensions were prepared from spleen (*a*), small intestine[20] (*b*), and parotid gland[21] (*c*), and Kupffer cells were isolated from the liver[22] (*d*) of outbred guinea pigs. The cells were surface labelled with ^{3}H (ref. 8), membrane proteins were solubilised with Triton X-100, glycoproteins were isolated by lectin affinity chromatography and indirect immunoprecipitations were carried out[7]. Control precipitates were generated with normal rabbit serum. Precipitated molecules were subjected to SDS–polyacrylamide gel electrophoresis. The control precipitates did not contain significant amounts of radioactivity (not shown). The immunosorbent-purified antibodies were derived from a rabbit antiserum against highly purified HLA-DR antigens. The reactivity of this antiserum has been documented in detail elsewhere[14] and it has been shown that this antiserum crossreacts extensively with guinea pig Ia antigens[23]. The antiserum was passed over a Sepharose-4B column containing highly purified, covalently bound HLA-DR antigens isolated from chronic lymphatic leukaemia cells (L.K., L.T., L.R. and P.A.P., submitted). The bound antibodies were desorbed with 0.2 M sodium citrate buffer, *p*H 2.9. After extensive dialysis against phosphate-buffered saline (PBS), *p*H 7.2, the antibodies were concentrated. The arrows (left to right) denote the migration positions of marker IgG heavy and light chains and the tracking dye bromphenolblue.

The results of the indirect immunofluorescence studies with use of the specific antibodies on cryostat sections from various tissues are summarised in Table 1. In all tissues examined only epithelial cells were stained. The exception to this was the liver where only the Kupffer cells reacted convincingly with the antibodies whereas the hepatocytes appeared devoid of Ia antigens. The earlier reports that the Langerhan's cells of epidermis express Ia antigens[11,12] were confirmed. The cornea contains similar types of cells as the antibodies bound specifically to cells displaying short dendritic processes. A strong, patchy fluorescence was noted along the border of all intestinal sections studied (Fig. 2*a*). The cells lining the bronchi in the respiratory tractus were generally stained rather diffusely. The epithelia of the gall bladder and the kidney pelvis (Fig. 2*b*) were well stained in some parts and weakly in others. The urinary bladder epithelium also reacted well with the antibodies inasmuch as a strong fluorescence was observed, particularly in the crypts. The mammary gland from virgin animals contained few if any cells that were stained by the anti-HLA-DR antigen antibodies. However, in sections of lactating mammary glands an intensive fluorescence was noted around the epithelial cells lining the ducts (Fig. 2*c*). These cells produce the milk fat droplets which are enveloped by plasma membrane from the epithelial cells[13]. Figure 2*d* shows that also the membranes of

0028-0836/78/0276—0711$01.00

the milk fat globules displayed a bright fluorescence after staining with the antibodies.

Antibodies gave a discrete but uniform fluorescence mainly on rather large cells when sections of thymus were examined. The antibodies do not react with thymocytes[14] so it seemed that the stained cells probably belonged to the reticuloepithelium.

The relative amounts of the anti-HLA-DR (Ia) antigen antibodies bound to single cells obtained from the small intestine and spleen were compared. Figure 3 shows that those spleen cells that bound the antibodies contained about threefold more

Table 1 Occurrence of Ia-antigen-like molecules on cells of various organs*

Tissue	Cell type stained†	Presence of Ia antigen subunits‡
Salivary glands (parotid and submandibular glands)	Glandular epithelium	+
Oesophagus (upper part)	Not detected	nt
Small intestine (duodenum; jejunum; ileum)	Epithelial cells	+
Colon	Epithelial cells	nt
Liver	Kupffer cells	+
Gall bladder	Epithelial cells	nt
Cornea	Langerhans-like cells	nt
Epidermis	Langerhans' cells	+
Mammary gland		
(virgin)	Few Ia-antigen expressing cells	nt
(lactating)	Epithelial cells	+
Trachea	Not detected	nt
Bronchi	Epithelial cells	nt
Urinary bladder	Epithelial cells	nt
Kidney pelvis	Epithelial cells	nt

* All analyses were performed on tissues from guinea pigs. Ia-antigen-like molecules were identified with use of immunosorbent-purified anti-HLA-DR antigen antibodies.

† Determined by indirect immunofluorescence on thin cryostat sections.

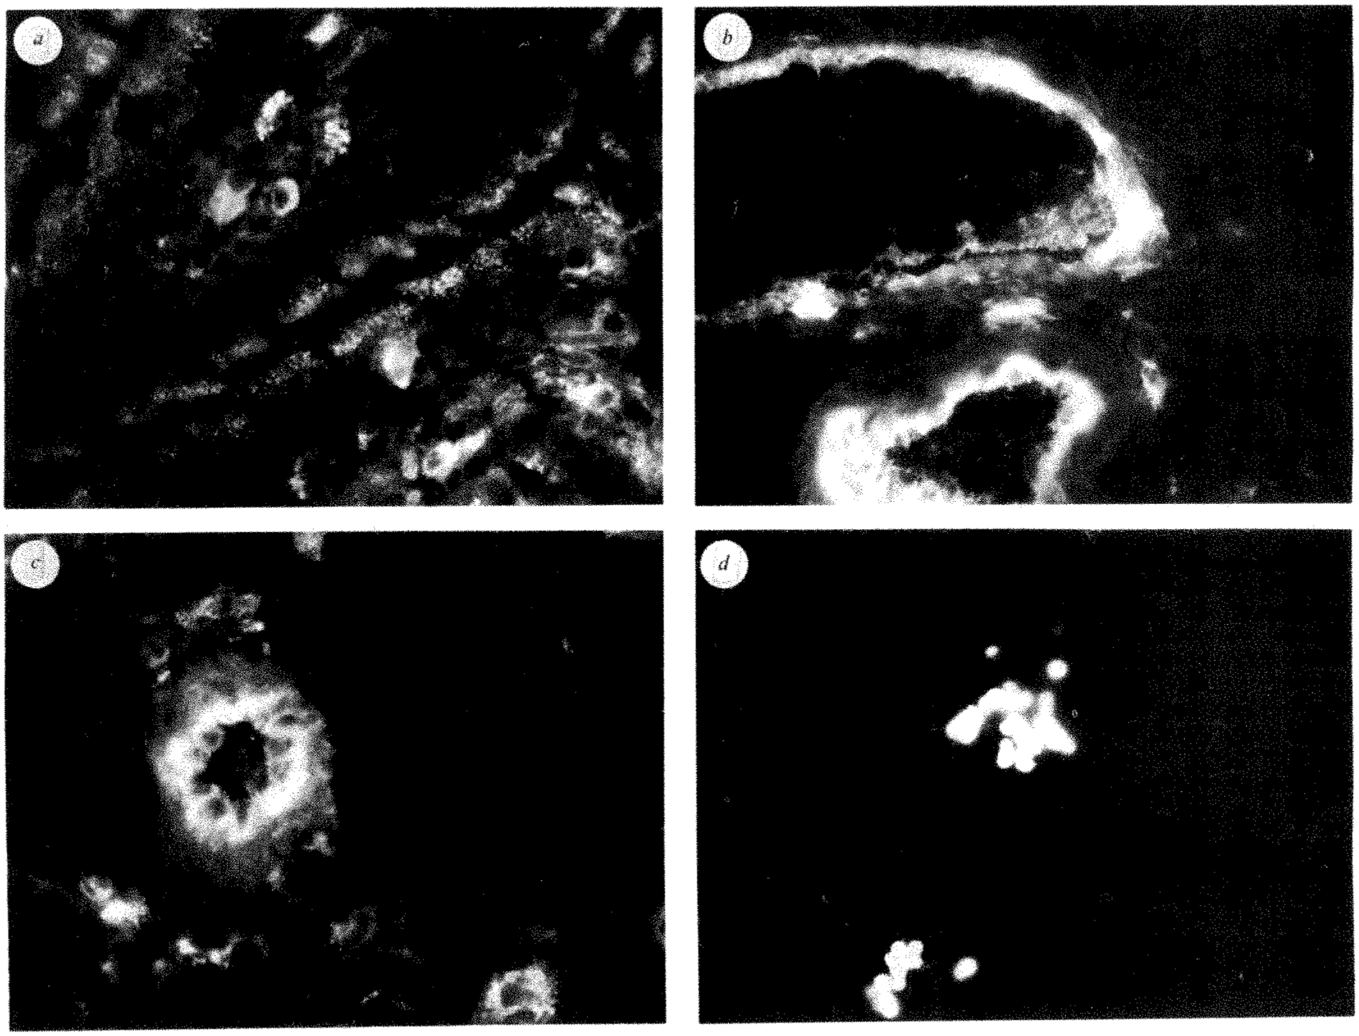

Fig. 2 Indirect immunofluorescence of thin sections of small intestine (*a*), kidney pelvis (*b*), lactating mammary gland (*c*) and milk fat globule membranes (*d*) of guinea pigs after staining with immunosorbent-purified anti-HLA-DR antigens antibodies (see legend to Fig. 1). The tissues were immediately frozen in cold isopenthane (−70 °C) and sections of 6 μm were subsequently prepared. The air-dried sections were incubated with 50-μl portions of the antibodies and normal rabbit IgG, respectively. The IgG-fractions, used at a concentration of about $10\ \mu g\ ml^{-1}$, were diluted in PBS, *p*H 7.2, containing 4% bovine serum albumin (BSA). The antibodies were allowed to react with the sections for 30 min at room temperature in a humidified atmosphere. The sections were then washed extensively in PBS–BSA and allowed to react with fluorescein-isothiocyanate-conjugated swine-anti-rabbit IgG antibodies (Dakopatts) at a concentration of $0.5\ mg\ ml^{-1}$. After an incubation period of 30 min and several washes in PBS–BSA the reactions were mounted in 10% glycerol-PBS, *p*H 7.2. The sections were examined in a Zeiss fluorescence microscope with incident light and blue narrow band activation (chromatic mirror 510 and interference filters KP 490 and KP 500 and orange filter LP 520) illuminated with an Osram HBO 200 lamp. Sections stained with normal rabbit IgG did not display any fluorescence (not shown).

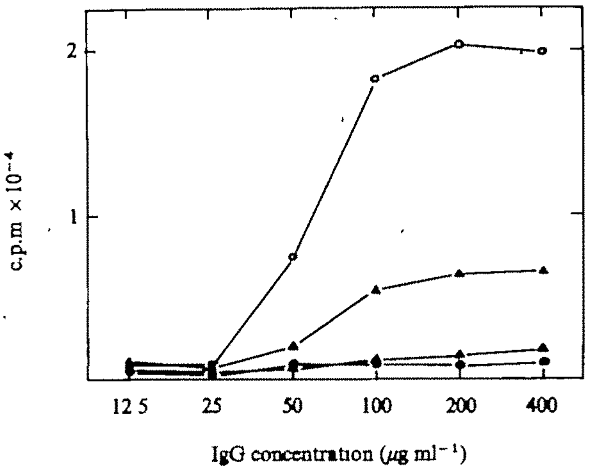

Fig. 3 Binding of immunosorbent-purified anti-HLA-DR antigen antibodies to guinea pig spleen cells (○,●) and to small intestine epithelial cells (△,▲). Aliquots containing 5×10^5 spleen cells and 2×10^5 epithelial cells[20], respectively, were incubated with various amounts of immunosorbent purified antibodies (○,△) and normal rabbit IgG (●,▲), respectively, in a final volume of 0.1 ml of PBS–BSA. After an incubation period of 30 min at +22 °C the cells were washed extensively and suspended in 0.05 ml of PBS–BSA containing saturating amounts of ^{125}I-labelled protein A (ref. 24). After a further incubation period of 30 min at 22 °C the cells were repeatedly washed and subjected to radioactivity measurement. Indirect immunofluorescence of the two single cell suspensions demonstrated that all of the epithelial cells but only about 40% of the spleen cells reacted with the antibodies. The number of spleen cells used in the binding experiment was adjusted accordingly.

of the radioactivity than did the intestine epithelial cells. As the latter type of cells are considerably larger than the lymphocytes the density of the Ia antigens per unit surface area on the epithelial cells must be only a fraction of that of the B lymphocytes.

This study was undertaken with use of immunosorbent-purified heteroantibodies. The occurrence on various tissues of molecules reactive with the antibodies does not necessarily imply that true Ia antigens were recognised inasmuch as the heteroantibodies may have cross-reacted with other components. This possibility seems unlikely, however, as the only cell surface-labelled glycoconjugates that reacted with the antibodies displayed the typical Ia antigen subunit pattern on SDS–polyacrylamide gel electrophoresis. Moreover, highly purified intestinal epithelial cells of mice will give rise to Ia antigen alloantibodies when injected into I-region congenic mice. Such alloantisera react with Ia antigens expressed on splenocytes. Some conventional anti-Ia antigen alloantisera also react specifically with the intestinal cells (B.C., L.R. and P.A.P., unpublished observations). Whether the Ia antigens present on cells of non-lymphoid origin belong to any particular sublocus of the MHC I-region remains to be elucidated.

The demonstration of Ia antigens on epithelial cells in various tissues has bearing upon clinical organ transplantations. The presence of Ia antigens on kidney cells is in keeping with the observation that HLA-DR antigen identity between the donor and the recipient is of as great importance as HLA-A,B,C antigen identity[15].

The association between some types of diseases and the HLA-DR antigen phenotype[16] also has bearing on the present findings. Thus, the expression of HLA-DR antigens of a given phenotype on cells of the disease-prone organs might represent an absolute requirement for manifestation of the disease.

It is interesting that Ia antigens are expressed on reticuloepithelial cells of the thymus in view of the recent observations that the education of T cells in the thymus is dependent on the I-region genotype of the reticuloepithelial cells[17]. It is tempting to suggest that it is the Ia antigens on the reticuloepithelial cells that are crucial for the functional maturation of the T cells. The abundance of IgA-secreting cells in various epithelia[18] may be related to the occurrence of Ia antigens in these tissues. This is particularly important for the mammary gland. In virgin animals very few IgA-secreting plasma cells are found in the gland but under the influence of lactotropic hormones IgA-secreting cells accumulate in the epithelium of the gland[19]. This sequence of events is strictly parallel to the expression of Ia antigens on the epithelial cells (L.K., U.F. and P.A.P., unpublished observations).

Localisation of Chido and Rodgers determinants to the C4d fragment of human C4

CHIDO (Ch) AND RODGERS (Rg) are blood-group antigens present in plasma and on red cells. Interest in these antigens was stimulated when Ch (ref. 1) and Rg (ref. 2) were found to be genetic markers for the major histocompatibility complex, HLA, and when strong linkage disequilibrium between the Rg-negative phenotype and HLA-A1, B8 homozygosity was noted[3]. Ch and Rg recently attracted a broad audience when O'Neill *et al.*[4] showed that the Ch and Rg phenotype of plasma was correlated with the electrophoretic polymorphism of human C4, the fourth component of complement, and that C4 purified

	Ch+, Rg−	9.24	0	0	>500	50	0	0
Anti-Le^{a} serum	Ch+, Rg+	none	>1,000	200			>8	>8

As a source of complement, serum, ACD plasma and EDTA plasma was obtained from donors of known Ch and Rg phenotype. Red cells were coated with complement by activation in low-ionic-strength solution (LIS): 10% aqueous sucrose[8]; 6% sucrose/0.15% NaCl (ref. 12); 9.24% buffered sucrose containing EDTA, purported to coat cells with C3 without detectable C4 (ref. 11). C4D serum was from a C4-deficient patient; C2D serum was from a C2-deficient patient. Immune transfer of complement to red cells was effected using fresh serum containing anti-Le. Red cells were tested with anti-complement reagents diluted in 22% bovine serum albumin (Ortho Diagnostics). Rabbit anti-human C4 (Behringwerke AG) reacted strongly with red cells coated with C4b but not with these cells after trypsin treatment, or with red cells sensitised *in vivo* with C4/C3, this serum is referred to as anti-C4c. Anti-C4d (two examples) was raised in monkeys injected intravenously with autologous red cells coated with C4d only; these sera were non-precipitating[5]. Anti-C3b (Behringwerke) was obtained as anti-human C3. Anti-C4c, anti-C4d, and anti-C3b were used unabsorbed at dilutions of 1 . 50 or greater. Anti-C3d was absorbed with human red cells. Six examples of anti-Ch and five examples of anti-Rg from patients immunised by transfusion or pregnancy were used.

* Weak and variable background reactions were observed at all dilutions of antiserum; these reactions were abolished by trypsin-treatment of the red cells and were probably due to immune adherence

to homogeneity inhibited anti-Ch and anti-Rg. We have studied the transfer of Ch and Rg from plasma to red cells in conditions in which C4 is transferred. We report here a correlation between the Ch, Rg polymorphism and functional C4, and show that Ch and Rg reside on the C4d fragment of the molecule. We also report that a monkey antiserum to human C4d (ref. 5) is predominantly anti-Ch and anti-Rg.

The antibodies anti-Ch and anti-Rg have been described as 'nebulous'[6] and 'serologically difficult'[7] because of their weak and variable reactions with red cells; Ch and Rg can usually be detected only by the antiglobulin test. We found, however, that Ch and Rg could be readily detected by direct agglutination using anti-Ch and anti-Rg when the antigens were transferred to red cells *in vitro* by activation of the classical complement pathway in low-ionic-strength solution (LIS). In 10% sucrose LIS[8], red cells became strongly Ch(Rg)-positive when serum or ACD plasma was used as a source of C4, but not when EDTA plasma was used; the Ch(Rg) phenotype acquired by the red cells was entirely dependent on the Ch(Rg) phenotype of the donor serum (Table 1). Red cells acquired both Ch and Rg from C2-deficient serum, but neither Ch nor Rg from C4-deficient serum; C4-deficient serum did not inhibit anti-Ch or anti-Rg. Heating serum to 56 °C for 60 min (ref. 9), or treatment with thiocyanate[10] which inactivates C4, C3 and C5, abolished the transfer of Ch(Rg) to red cells in LIS. Using a LIS technique[11] which coats red cells with C3b without C4, the cells did not acquire Ch(Rg). Immune transfer of Ch(Rg) was demonstrated by exposing Le(a+) red cells to fresh serum containing complement-binding anti-Le^{a} (Table 1).

We found that Ch+, Rg− and Ch−, Rg+ serum could be readily distinguished from Ch+, Rg+ serum by the amount of C4 transferred to red cells in 6% sucrose/0.15% NaCl LIS[12], but such a distinction could not be made when 10% sucrose LIS was used (Table 1). This finding was unexpected but accords with the known correlation between the immunochemical polymorphism of C4 and functional activity of the molecule[13]. Determination of plasma C4 by single radial immunodiffusion (Behringwerke plates) showed that Ch+, Rg+ plasma usually contained more C4 than Ch+, Rg− plasma did, and that Ch−, Rg+ plasma contained the least C4. However, when Ch+, Rg− or Ch−, Rg+ plasma could be matched for C4 content with Ch+, Rg+ plasma, the amount of C4, Ch, Rg transferred in 6% sucrose/0.15% NaCl LIS was again correlated with the Ch(Rg) phenotype. This result suggests that there are intrinsic differences in the activity of C4 molecules of different Ch, Rg phenotype.

Previous studies assessing the effects of reducing agents and enzymes[14] on incomplete blood-group antibodies suggested that, in agglutination tests, the Chido antigen on normal red cells is not destroyed by trypsin. We investigated further this apparent localisation of Ch(Rg) to a trypsin-resistant fragment of C4. In a kinetic study, red cells coated with C4, Ch, Rg in 10% sucrose LIS lost all reactivity with anti-C4c within about 2 min of exposure to trypsin at 37 °C, whereas C4d and Ch(Rg) determinants still remained at 60 min (Table 2). C4d and Ch(Rg) determinants were resistant to further cleavage, by chymotrypsin, in conditions in which C4c determinants were lost from cells coated with C4b in LIS (Table 2). The reactions of anti-Ch and anti-Rg with cells treated with trypsin, however, became slightly weaker with time indicating some alteration or destruction of Ch(Rg) with prolonged exposure to the enzyme. This finding correlates with the observation that, in the antiglobulin test, Ch and Rg on normal red cells are much weaker after enzyme-treatment. Since agglutination tests confirmed that Ch(Rg) is borne by a tryptic-C4d fragment of C4, we tested red cells expected to carry C3bINA-cleaved C4d due to complement-activation *in vivo*[15,16]. Such cells, collected into EDTA from patients with cold autoimmune haemolytic anaemia, failed to react with anti-C4c but were strongly agglutinated by anti-C4d, and by anti-Ch and anti-Rg (Table 2).

In all experiments anti-Ch(Rg) behaved the same as anti-C4d. As the monkey anti-C4d was non-precipitating[5], it might be directed against few antigenic determinants, possibly just Ch and Rg. In inhibition tests using red cells coated with C4d, Ch, Rg, the anti-C4d was inhibited by Ch+, Rg+ serum but there was no detectable inhibition with Ch−, Rg+ or Ch+, Rg−

serum. Anti-C4d was inhibited by mixing Ch−, Rg+ and Ch+, Rg− serum but the inhibition was less than with Ch+, Rg+ serum. Thus this anti-C4d is predominantly anti-Ch and anti-Rg. This surprising finding presumably reflects the phylogenetic proximity of monkeys to man.

The preservation of Ch and Rg on C4-sensitised red cells exposed to trypsin and chymotrypsin *in vitro*, or C3bINA *in vivo*, indicates that these antigens reside on the limit fragment, C4d, which is stably associated with the cell surface[17]. Ch and Rg must, of course, be spatially distant from that portion of C4 which interacts with the membrane. It is interesting that Ch and Rg survive cleavage and presumed conformational change in C4 which precede transfer of the molecule to the red cell. Conformational changes presumably also accompany processing of single-chain precursor C4 (ref. 18) to the mature three-chain structure; anti-Ch(Rg) could be used as a probe for such changes. As the structural locus for C4 (refs. 19, 20) and *Ch* (ref. 1) and *Rg* (ref. 2) all map to the same small region of chromosome 6, it is likely that primary structural differences, rather than some obligatory post-translational modification such as glycosylation[21], generate the Ch, Rg antigenic polymorphism. It does not follow, however, that the electrophoretic polymorphism of C4 is entirely due to the structural differences in C4d which distinguish Ch from Rg. Certainly, in some gel systems[22,23] the apparent structural variability cannot be explained solely by Ch and Rg differences. The structural polymorphism of C3 is, in fact, in the C3c fragment[24,25], and C4 and C3 are homologous proteins.

Graham *et al.*[26] have shown that C3d is present on normal red cells. To the extent that normal red cells carry detectable Ch and Rg, these cells are also coated with C4d. A cardinal question, therefore, concerns the origin of the natural Ch(Rg) on red cells. Does natural Ch(Rg) represent low-level sensitisation with C4 during physiological activation of the classical complement pathway, or is it bound by a different mechanism? A unified hypothesis that all Ch(Rg) on red cells is dependent on complement activation would accommodate the serological differences between natural Ch(Rg), and Ch(Rg) acquired by known activation of complement. The nebulous and variable reactions of anti-Ch and anti-Rg with normal red cells are presumably due to only trace amounts of C4d on the cells.

Table 2 Effect of enzymes on C4, Ch(Rg) bound to human red cells

One volume of packed red cells, coated with C4, Ch, Rg in 10% sucrose LIS containing Ch+, Rg+ serum, was incubated at 37 °C in four volumes of 1 mg ml^{-1} Trypsin-TPCK (Worthington Biochemical) in 20 mM Tris-HCl/0.15 M NaCl, pH 7.8 (TBS). At intervals, an aliquot of red cells was removed, centrifuged through a large volume of saline, and washed a further three times. After 30 min, a portion of these cells and cells freshly coated with C4, Ch, Rg were incubated with α-chymotrypsin (Worthington), 1 mg ml^{-1} TBS containing 10 mM $CaCl_2$ for 30 min at 37 °C, then washed three times. Red cells coated *in vivo* with C4/C3 were obtained from patients with cold autoimmune haemolytic anaemia In two Ch+, Rg+ patients the auto-antibody had I specificity, in one patient, who was Ch+, Rg−, the auto-antibody had P specificity. The anti-complement reagents used are described in the footnote to Table 1.

* Haemagglutinin titre. † One volume fresh trypsin added at 30 min

As a number of complement components exhibit polymorphism, there is a potential for formation of alloantibodies to these components by transfusion. However, these components may have to be cell-bound to elicit an immune response. Anti-Ch and anti-Rg, elicited by C4, may be the first examples of alloimmunoconglutinins in man.

We thank Dr J. Freedman for providing anti-C4d and anti-C3d, Drs G. J. O'Neill and H. D. Ochs for C2D and C4D sera and Drs G. J. O'Neill and B. Dupont for discussing their findings[4] with us before publication. This work was supported by the Blood Research Fund of the University of Toronto. D.G.R. is a Fellow of the M.R.C. of Canada.

Effective subunit vaccines against an enveloped animal virus

VACCINES are available to act against many of the diseases caused by enveloped viruses. The efficacy and safety of the vaccines depend on the method used to convert the virus into a vaccine. Whole viruses that have been attenuated or killed are effective, but both of these types of vaccines may give rise to undesirable side effects which limit their use[1–3]. These complications are caused by the virus genome or by toxic components in the virus preparations. The components that give rise to the side effects do not seem to be those that are important for evoking protective immunity and it is therefore possible to prepare vaccines which contain only the necessary antigenic subunits, which for the enveloped viruses are the spike glycoproteins[4–7]. But although subunit vaccines have proved safer

Table 1 Chemical composition of subunit vaccines used

Vaccine preparation	Polypeptide composition	Molecular weight	No. of virus spikes per complex	Lipid content (mg per mg protein)	Detergent content (mg per mg protein)	Infectivity* (PFU)	Ref.
4.5S complexes	E1, E2, E3	1.5×10^5	1	0.01	0.54	NT	16
29S complexes	E1, E2, E3	9.5×10^5	8	0.01	0.03	<10	17
Virosomes	E1, E2, E3	—	~20–2,000†	0.9–1.0	0.05	<10	15

NT, not tested (detergent interferes with assay).

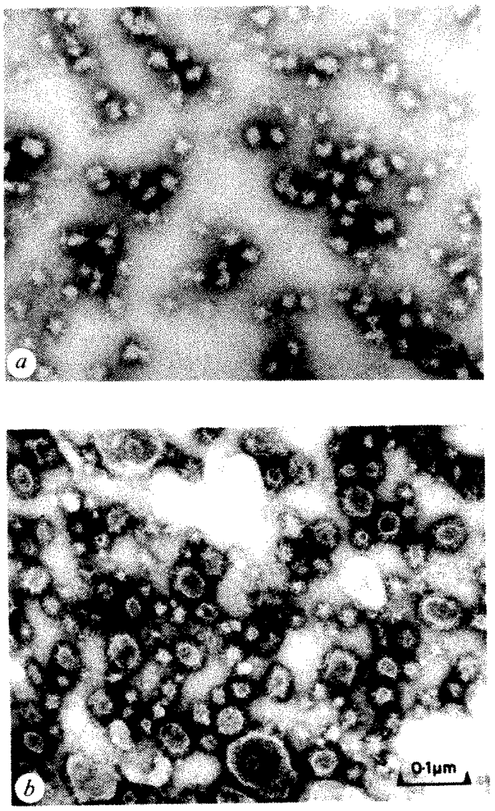
* Infectivity assayed by plaque titration in BHK-21 cells[33] at a protein concentration of 0.2 mg per ml.

† The virosomes consist of a heterogeneous population of vesicles of different sizes.

than whole virus vaccines, their immunogenicity is generally lower[8,9], perhaps because the form in which the proteins are presented in the vaccines is not optimal for eliciting a strong immune response[10]. In support of that explanation, we present here evidence that a lethal infection of mice with Semliki Forest virus can be prevented by a single vaccination with the virus spike protein, provided it is presented as a micellar aggregate of the protein or as protein reconstituted into vesicles of egg lecithin. The monomer form of the spike protein solubilised with detergent is very much less effective.

Semliki Forest virus (SFV) is well suited for the studies outlined above[11,12]. It is a simple enveloped virus in the Togaviridae family. In mice lethal strains cause encephalomyelitis which leads to death within a week. The surface glycoproteins of this virus have been studied in detail[13]. Systematic studies of the solubilisation[14] and reconstitution[15] of the virus membrane have yielded methods for the preparation of three different physical forms of the spike protein; (1) the 4.5S complex[16], a complex of one spike protein bound to 75 molecules of Triton X-100; (2) the 29S complex[17], a protein micelle of eight spikes virtually devoid of lipid and detergent and with a molecular weight of 9.4×10^5; and (3) virosomes (see ref. 18 for terminology) in which the spike proteins have been reconstituted into vesicles of egg lecithin[15].

Fig. 1 Electron micrographs of *a*, the 29S complexes and *b*, the virosomes used for vaccination. The preparations have been negatively stained.



The vaccine preparations for these studies were made from the prototype strain of SFV which has been passaged in BHK-21 cells several times in our laboratories and is avirulent for mice. Monomers of spike proteins were isolated as 4.5S complexes from the purified virus by disrupting the virus with Triton X-100 and then subjecting this mixture to sucrose gradient centrifugation in the presence of a detergent[16]. The proteins obtained are virtually lipid-free and soluble by virtue of the bound detergent. The 29S complexes were prepared by centrifugation of virus disrupted with Triton X-100 into a sucrose gradient, which separates the lipid, detergent and nucleocapsids from the spike proteins[17]. These aggregate to octameric complexes which are water soluble (Fig. 1*a*). They are similar in structure to detergent micelles. The protein micelles have a polar surface and the hydrophobic tails of the spike proteins are buried in the interior[19]. Other virus spike proteins also aggregate to form soluble complexes (see ref. 19). The virosomes were prepared by the octylglucoside dialysis method[15]. Briefly, the virus was solubilised with Triton X-100 and the spike glycoproteins isolated by sedimentation into a sucrose gradient containing the nonionic detergent β-D-octylglucoside. Egg lecithin solubilised with octylglucoside was added (the lipid/protein ratio being 1 : 1, w/w) and the detergent removed by dialysis (Fig. 1*b*). The properties of the three vaccines are summarised in Table 1.

The amount of 29S complex required to induce protective immunity after a single inoculation into BALB/c mice was studied first. A virus does of 10^4 plaque forming units (PFU) of the lethal L10 strain[11] was used to challenge the mice two weeks after vaccination. The response to increased doses of the vaccine was linear; 0.5 μg of 29S vaccine was sufficient to protect 50% of the mice. A dose of 10 μg induced protection in all animals. Therefore, 10 μg of virus protein was subsequently used in all experiments. We carried out three series of experiments using the three forms of vaccines (Table 2). In the first, the challenge

Table 2 Vaccination against SFV encephalomyelitis in BALB/c mice: the protective effect induced by different forms of purified spike protein vaccine

Physical form of vaccine	Dose (μg protein)	LD_{50} of challenge virus ($\log_{10}$ of PFU) Expt 1	Expt 2	Expt 3
(control)		2.3	2.1	2.6
4.5S complex (monomer)	10	ND	2.7	3.4
29S complex (octamer)	10	>3.5	>5.3	>6.3
Virosome (multimer)	10	>4.0	>5.1	>6.6

The vaccination experiments were performed on 5–6-week-old female BALB/c mice. The mice were vaccinated with a single dose of 10 μg spike protein in 100 μl Eagle's minimal essential medium. One third of the dose was injected subcutaneously and two thirds intraperitoneally (i.p.). Two weeks later groups of 10 mice were challenged i.p. with virulent strain L10.H6.C1 SFV with doses ranging from 50 to 10^4 PFU (Expt 1) 50 to 10^5 PFU (Expt 2) and 50 to 10^7 PFU (Expt 3). The infectivity was determined by plaque titration in BHK-21 cells[33]. The amount of protein in the vaccine preparations was measured by the method of Lowry *et al.*[34] using 0.1% SDS in the reaction mixture. The LD_{50} was calculated as described by Spearman and Kärber[35]. ND, Not determined.

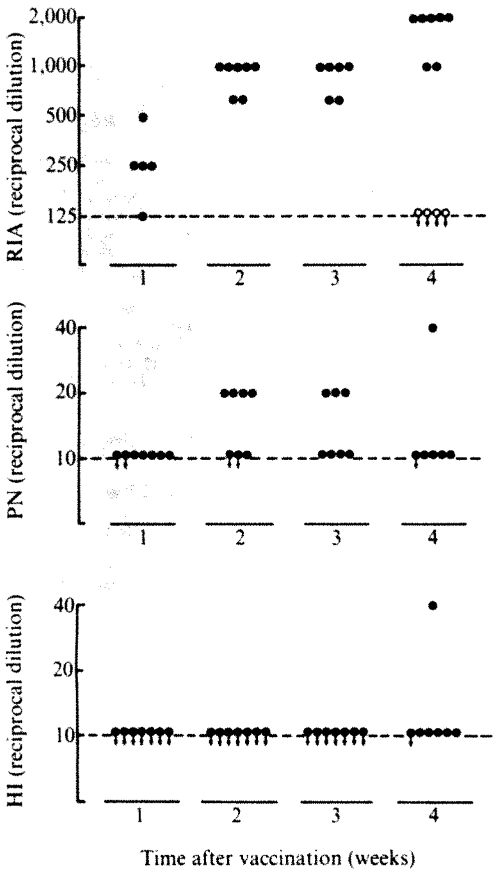


Fig. 2 The antibody response in serum of normal BALB/c and BALB/c nude (*nu/nu*) mice following vaccination with 10 μg SFV spike protein in virosomes. The sera from normal mice were collected weekly 1–4 weeks after vaccination. The nude mice were challenged with 10^3 PFU virulent virus two weeks after vaccination and after a further two weeks the sera from survivors were collected. The radioimmunoassay (RIA) was carried out in a solid phase system using flexible microtitre plates with U-formed bottom (Cooke no. 22–24). The wells were filled with 1 μg virus in 80 μl phosphate-buffered saline (PBS) and incubated overnight at 4 °C. Thereafter the wells were rinsed 3 times with 100 μl PBS, 30% fetal calf serum and 100 μl of mouse serum to be assayed was added in different dilutions and incubated for 1 h at room temperature. After washing 100 μl of immunosorbent purified ^{125}I anti-mouse γ globulin was added and incubated for 1 h at room temperature. After washing, the wells were cut out and radioactivity determined in a gamma counter (Nuclear Chicago). All sera were tested in triplicate and sera from non-immunised were included as negative controls. The titre was defined as the highest dilution of serum which bound more than 2 times the amount of radioactivity of normal mouse serum controls. The plaque neutralisation (PN) test and the haemagglutination inhibition (HI) test were performed as described previously[32,36]. ●, Titres from individual normal BALB/c mice; ○, titres from individual nude mice. The arrow indicates that the titre was below the dilution tested. ---, threshold level of the test, that is, the lowest dilution tested.

dose ranged from 50 to 10^4 PFU and in the second and third series the maximum challenge dose was increased to 10^5 and 10^7 PFU, respectively. Even with the highest challenge dose (10^7 PFU) most of the mice vaccinated with the 29S complexes and the virosomes survived. The extent of protection measured by the difference between the LD_{50} in controls and in the groups vaccinated with a single dose of 29S complexes and of virosomes must thus be higher than $10^{3.7}$ (Table 2). We also vaccinated a group of 10 mice twice with virosomes (10 μg spike protein) two weeks apart and challenged them 14 days later. All the mice survived the highest dose of virus (10^7 PFU).

Mice vaccinated with the 4.5S complex were only slightly protected (Table 2). To verify the very small difference induced by the 4.5S complex, the non-vaccinated mice and the mice vaccinated with the 4.5S complexes that survived the first challenge dose of virus were given a second challenge of 10^4 PFU of virus (Table 3). All but one of the non-vaccinated mice died, whereas the survival of the vaccinated mice was dependent on the dose of virus given in the first challenge. If the first challenge was higher than one LD_{50} dose ($>10^2$ PFU), the mice survived the second challenge. Thus vaccination with the monomeric form of the spike protein gave a small but detectable protection against the disease.

Table 3 Enhancement by live virus challenge of a poor protective effect induced by vaccination with 4.5S complexes

Vaccine* (day 0)	1° Challenge (day 14) Dose (PFU)	Mortality†	2° Challenge (day 28) Dose (PFU)	Mortality	Comments
None	$10^{1.5}$	0/10	10^4	10/10	No protection obtained after 1st challenge
	$10^{2.0}$	1/10	10^4	9/9	
	$10^{2.5}$	5/10	10^4	4/5	
	$10^{3.0}$	24/30	10^4	6/6	
4.5 complex (10 μg protein)	$10^{1.5}$	0/10	10^4	8/10	First challenge with a dose $<1\ LD_{50}$
	$10^{2.0}$	3/10	10^4	5/7	
	$10^{3.0}$	4/10	10^4	0/6	First challenge with a dose $>1\ LD_{50}$
	$10^{4.0}$	8/10	10^4	0/2	

* Vaccination was performed as described in Table 2. First challenge was performed 2 weeks after vaccination, and a second challenge after a further 2 weeks. For details see Table 2.

† Mortality expressed as number of mice killed per total number of group.

The dependence on T cells for induction of protective immunity using virosomes was studied by comparing the response of BALB/c mice with that of BALB/c nude (*nu/nu*) mice (Table 4). The LD_{50} for non-immunised nude mice was higher than for normal BALB/c. In contrast to normal mice no difference in survival time or rate between non-vaccinated and vaccinated mice was observed in *nu/nu* animals. The total serum antibody response was measured with a radioimmunoassay. No antibodies were detected in vaccinated nude mice which were challenged after two weeks and tested after four weeks. In normal mice the serum antibody titres kept rising from the first to the fourth week after immunisation. Antibody against SFV was detectable by plaque neutralisation assays 2 weeks after vaccination, and antibody causing haemagglutination inhibition after four weeks. The titres were low (Fig. 2). The above results suggest that T cells are required for protective immunity, as has been found for several viruses[20]. More detailed immunological studies are underway to explore the mechanisms of protection against SFV infection.

Previous studies have also shown that solubilisation of togaviruses with different mild detergents leads to vaccines with low efficacy[12]. Monomeric forms of spike proteins have been isolated from other enveloped viruses, and they too are poor immunogens. In contrast to SFV spike protein the Friend leukaemia virus spike glycoprotein (gp71) is a typical peripheral membrane protein which does not need detergent for solubility and seems to be attached to the viral membrane through another integral membrane protein[21]. The mice were only partially protected against leukaemia after vaccination with two doses of 100 μg of spike protein in Freund's adjuvant[5,21]. A monomer preparation of the influenza virus haemagglutinin has been prepared by releasing the hydrophilic portion of the spike using a protease[22]. This monomer haemagglutinin was only weakly immunogenic in hamsters and man[23,24]. These results agree with the known poor immunogenicity of monomeric compared with multimeric forms of proteins[25–27]. Monomers of spike protein, water soluble with or without detergent, are clearly not suitable as subunit vaccines. One reason why the virosomes and the protein micelles proved so efficient as vaccines is probably due to the multimeric structure of the spike proteins. The virosomes

Table 4 Resistance of vaccinated and non-vaccinated nude and normal BALB/c mice to infection with a lethal strain of SFV

	Nude			Normal		
Vaccine	Challenge dose (PFU)	No of mice killed per group	Survival time (d)	Challenge dose (PFU)	No of mice killed per group	Survival time (d)
Virosome	10^4	8/9	9.3±5.9	10^4	0/10	—
None	10^4	8/10	13.0±5.5	10^4	10/10	4.4±0.52
Virosome	10^3	1/5	7	10^3	0/10	—
None	10^3	0/5	—	10^3	9/10	5.11±0.93
Virosome	$10^{2.5}$	1/5	6	$10^{2.5}$	0/10	—
None	$10^{2.5}$	2/5	6	$10^{2.5}$	10/10	5.3±1.06

Mice were vaccinated with virosomes containing 10 μg spike protein and challenged 14 d later with different doses of virus. For details see Table 2.

contain a high surface density of spike protein similar to the surface of the virus itself. The 29S complexes contain eight spike proteins held together by their hydrophobic ends. Both forms bind effectively to the surface of cells apparently in such a way that spike proteins remain available for interaction with cells of the immune system[28]. We have recently shown that 29S complexes bind to virus receptors on the cell surface and do not seem to integrate into the cell membrane[29]. These findings suggest that integration of viral antigens into host cell surface membranes may not be a prerequisite for induction of protective immunity.

Another reason for the effectiveness of these vaccines is probably that mild methods were used to extract the spike proteins from the virus and to prepare the multimeric vaccines. Triton X-100 and octylglucoside are non-ionic detergents known to preserve the biological activities of membrane proteins[30,31]. Organic solvents and other denaturing agents such as ionic detergents may destroy antigenic determinants on the spike proteins. Whether protein micelles or virosomes will prove efficient as vaccines for other enveloped viruses has yet to be investigated.

We thank Dr G. E. G. Smith for prototype SFV, Dr C. J. Bradish for L10.H6.C1 SFV, Hilkka Virta for virus production, Eva Bolzau and Talmon Arad for electron microscopy, Peter Robinson for providing anti-mouse Ig, Graham Warren for reading the manuscript. B.M. was supported by an EMBO fellowship, and part of the work was supported by grants from the Finnish Academy.

Fibronectin binds to *Staphylococcus aureus*

MANY important activities have been ascribed to fibronectin, which is found in soluble form in many biological fluids and in insoluble form on the surface of fibroblasts[1–3]. Fibronectin mediates the attachment of fibroblasts and hepatocytes to culture dishes[4–6] and, when solubilised from the fibroblast surface, it binds to the surface of cultured transformed fibroblasts, restoring their morphology to normal[7,8]. I now report that the affinity of fibronectin to cell surfaces extends to the prokaryotic cell *Staphylococcus aureus*.

When labelled fibronectin was incubated with both commercial strains and clinical isolates of *S. aureus* up to 70% of the radioactivity bound to the bacteria. *Mycobacterium butyricum*, however, showed only slight binding (Fig. 1). No ^{125}I-α-feto protein bound to staphylococci nor did fibronectin bind to formalinised sheep red blood cells.

Table 1 Enrichment of fibronectin with *Staphylococcus aureus*

	Fibronectin concentrations in supernatants and eluates (μg ml^{-1})			
	Expt 1		Expt 2	
	Supernatant	Eluate	Supernatant	Eluate
S. aureus	0.1	11.5	0.3	12.5
M. butyricum	6.2	0.6	4.6	0.8
Control*	ND	ND	2.9	0.7

Citrated human plasma, 10–20 μl, containing 200–500 μg ml^{-1} fibronectin was diluted to 0.5 ml with phosphate buffered saline (PBS) and incubated with 0.5 ml 10% suspension of bacteria overnight. Supernatants were collected after centrifugation at 1,000 *g* for 30 min, and the bacteria were washed two times with 2.0 ml PBS. Fibronectin bound to bacteria was eluted adding 150 μl 8 M urea containing 0.05 M Tris, *p*H 8.0, and fibronectin was quantitated by radioimmunoassay. ND, not determined.

* Control tubes were processed as above without any bacteria.

Staphylococcal binding was confirmed using unlabelled fibronectin. After incubation of normal human plasma with *S. aureus* and *M. butyricum*, radioimmunoassay[9] showed marked enrichment of fibronectin in eluates of staphylococci but not in eluates of mycobacteria or in control eluates (Table 1).

To characterise the binding, various substances were tested for the capacity to inhibit binding of ^{125}I-fibronectin to staphylococci. As expected, unlabelled fibronectin was inhibitory, giving half maximal inhibition at 3–4 μg per ml of purified fibronectin. Inhibition by plasma samples containing known amounts of fibronectin was compatible with inhibition by purified fibronectin in the absence of plasma components (Fig. 2). Of the sugars tested, only nonacetylated amino sugars were inhibitory. Half maximal inhibition was obtained with 0.5 M solutions (Table 2). L-Lysine and urea were also inhibitory, whereas divalent cations or chelating agents had no effect on binding. Denatured collagen showed a maximal binding of only 18%, which was not concentration-dependent between 100 μg ml^{-1} and 5 mg ml^{-1}. This slight inhibition might be due to steric inhibition by collagen molecules bound to fibronectin. Protein A, which is present in the cell wall of *Staphylococcus aureus* and binds to immunoglobulins, did not inhibit at 100 μg ml^{-1}. Also F(ab')$_2$ fragments of purified anti-fibronectin antibodies failed to inhibit staphylococcal binding but inhibited the binding of fibronectin to collagen-Sepharose (data not shown). F(ab')$_2$ fragments were used rather than whole antibodies to avoid the binding between protein A and Fc fragments of antibodies.

Thus the binding of fibronectin to *S. aureus* resembles the binding of cells to collagen-coated culture dishes, a process in which fibronectin has been shown to mediate attachment[4,5,10]. Like staphylococcal binding, attachment to culture dishes is inhibited by amino sugars and lysine, although divalent cations are not required for the process. The lack of inhibition of staphylococcal binding in the presence of denatured collagen shows that this binding is not related to the binding of fibronectin to collagen[11].

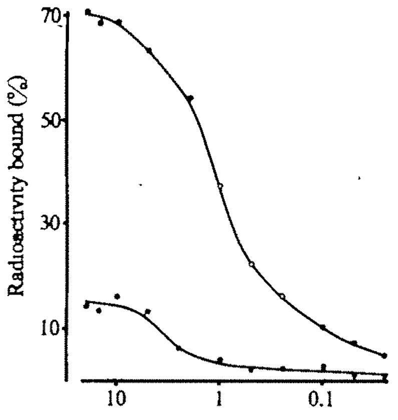

Fig. 1 Binding of ^{125}I-human fibronectin to fixed *S. aureus* (○) and *M. butyricum* (●). Fibronectin was isolated from normal citrated human plasma using affinity chromatography on denatured collagens[11] and radioiodinated using the chloramine-T method[9]. The labelled fibronectin showed a sharp peak of radioactivity co-migrating with the unlabelled fibronectin (MW 220,000) in SDS–polyacrylamide gel electrophoresis in the presence of β-mercaptoethanol[12]. Commercially available heat-killed and formalin-fixed *S. aureus* (Pansorbin, Calbiochem) and *M. butyricum* (Difco) were used. *S. aureus* isolated from routine clinical specimens, heat-killed and fixed with 10% trichloroacetic acid was also used in some experiments, with the same results. The bacteria were washed once with 5 volumes of 4.0 M urea solution containing 0.05 M Tris, pH 7.5, twice with 15–20 times the volume of buffer without urea, and used as a 10% suspension (v/v) in PBS containing 0.1% bovine serum albumin (BSA). Decreasing amounts of 10% bacterial suspension were adjusted to 1.0 ml with PBS–BSA, and ^{125}I-human fibronectin (1.0–1.5 × 10^4 c.p.m.) was added in 50 μl. After incubation overnight at room temperature under continuous rotation, the bacteria were isolated by centrifugation (1,000*g* for 30 min), washed once with 1.0 ml PBS–BSA, and transferred in 250 μl of PBS–BSA into new tubes for counting. Each point represents the mean of duplicate tubes.

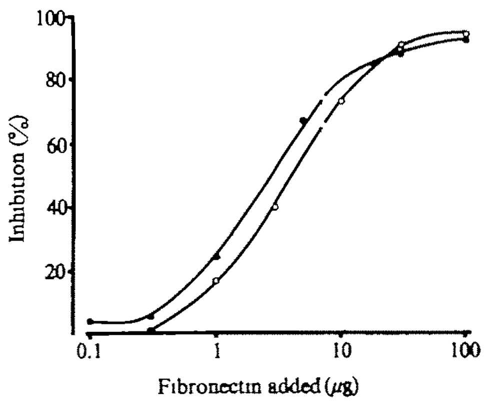

Fig. 2 Inhibition of binding of ^{125}I-human fibronectin to *S. aureus* with normal human plasma (●) and fibronectin isolated from human plasma (○). Increasing amounts of normal human plasma, containing 210 μg ml^{-1} fibronectin, and isolated human plasma fibronectin were incubated with 50 μl of a 10% bacterial suspension. This amount of suspension gave about 50% of maximal binding. The test was carried out as for Fig. 1. Inhibition percentages were calculated according to the formula:

$$\frac{[\text{Binding \% without inhibitor} - \text{binding \% with inhibitor}]}{\text{Binding \% without inhibitor}} \times 100.$$

This conclusion is further supported by the observation that F(ab')$_2$ fragments of anti-fibronectin antibodies do not inhibit staphylococcal binding but inhibit and reverse the binding of fibronectin to collagen[9]. Whether fibronectin also binds to living *S. aureus* and whether it is the anti-staphylococcal factor remains to be seen. If staphylococcal binding is an expression of the affinity of fibronectin for cell surfaces, it could prove useful in the elucidation of the nature of the cellular receptor(s) involved.

Table 2 Inhibition of binding of labelled human fibronectin to *Staphylococcus aureus*

Inhibitor	Concentration needed to inhibit binding (mM) 20%	50%
D-Glucosamine[a]	150	500
D-Galactosamine[a]	ND	500
L-Lysine[b]	100	>1,000
NaCl	100	>2,000
Urea	600	1,050
Anti-human fibronectin F(ab')$_2$ (μg ml^{-1})	>190	—

Binding assay and calculations for inhibition percentages were as described in Figs 1 and 2. The solutions were neutralised with NaOH (a) or with HCl (b) before incubation with bacteria. Amino sugars were used in HCl form, and they were neutralised to pH 7.5 with NaOH before testing. Conductivity measurements showed that 0.5 M stock solutions of these sugars contained the equivalent of 0.2 M NaCl above the conductivity of PBS–bovine serum albumin–buffer alone. This amount of NaCl inhibited the binding 28%. F(ab')$_2$ fragments of purified rabbit anti-human fibronectin antibodies were obtained as follows: 2.4 mg purified antibodies were incubated with 500 μg pepsin in 0.1 M sodium acetate buffer, pH 4.5, overnight at room temperature. Digestion was stopped by dialysis against 0.05 Tris-HCl buffer, pH 8.0, and the digest was passed through a Sepharose–protein A column. Protein peak consisting of unbound material was collected and used in the tests. No inhibition was obtained with the following substances. 1 mM MgCl$_2$ and CaCl$_2$, 100 mM EDTA and EGTA, 0.5 M D-glucose, D-galactose, D-*N*-acetylglucosamine, D-*N*-acetylgalactosamine, L- and D-fucose, D-mannose, L-rhamnose, L- and D-xylose, 0.25 M D-*N*-acetylneuraminic acid and 1 M glycine. ND, not determined.

I thank Dr Eva Engvall for discussions, Dr John Vice for help and Dr Erkki Ruoslahti for support and for ^{125}I-α-fetoprotein. This work was supported by grants CA 22108 and CA 16434 from the NCI.

The amino acid sequence of *Physarum* actin

THE realisation that actin is involved not only in contractility in muscle tissue but also in general cytoplasmic movement and cell locomotion was based on the isolation of actin from lower eukaryotic organisms, such as *Physarum polycephalum*[1], which show active protoplasmic streaming. It is now accepted that actin is the major structural protein of microfilaments characteristically found in the cytoplasm of most if not all higher cells, and that actins have been highly conserved during eukaryotic evolution and differentiation due to the constraints imposed by the large number of specific interactions which actin shows with other cytoplasmic proteins (for a review see ref. 2). Preliminary fingerprint analysis on *Physarum* actin[3] and partial amino acid sequence analysis on actin from *Acanthamoeba* (ref. 4 and Elzinga cited in ref. 2) have emphasised this point, although so far a complete amino acid sequence has not been reported for actin from a lower eukaryotic species. Our studies on the primary structure of different mammalian actins have shown that several cytoplasmic actins are very similar if not identical in amino acid sequence, although they differ by at least 25 amino acids from the corresponding skeletal muscle actin[5]. The availability of fast amino acid sequence procedures for actin[5] led us to study the actin from *Physarum polycephalum* to assess how cytoplasmic actins differ between lower and higher eukaryotes. We report here results which show that *Physarum* plasmodia, in contrast to non-muscle cells of higher vertebrates[5–7], contain only one cytoplasmic actin species. This actin is more closely related to mammalian cytoplasmic actins than these actins are to skeletal muscle actin. The high degree of structural conservation of the actin sequence and structure during eukaryotic evolution is illustrated by the absence of any amino acid deletions or additions to the polypeptide chain beyond residue 2. Furthermore, the distribution of the proline residues remains unchanged and substitutions of amino acid residues with charged side chains are very rare, indicating a high conservation of the surface topography of the actin molecule.

Actin was purified from an acetone powder prepared from *Physarum* plasmodia. A low salt extract was chromatographed on deoxyribonuclease I immobilised on Sepharose 4B as described elsewhere[5,8]. The resulting actin preparation was at least 95% pure as judged by polyacrylamide gel electrophoresis in the presence of dodecyl sulphate, where *Physarum* actin coelectrophoreses with mammalian actins. In addition, isoelectric focusing analysis in the presence of urea and NP40 revealed a single protein species, focusing, in agreement with previous studies[9], very close to although at a slightly more acidic *p*H than rabbit skeletal muscle actin. *Physarum* actin was processed through performic acid oxidation and tryptic digestion as described for other actins[5,10]. Peptides were separated by the preparative two-dimensional 'fingerprint' system on Whatman 3MM paper which we have described in detail previously[5,10,11]. The insoluble tryptic 'core' was digested with thermolysin and the resulting peptides purified as described elsewhere[5]. This system accounts by tryptic and thermolytic peptides for the full amino acid sequence of the actin polypeptide chain[5]. All peptides were characterised by their electrophoretic and chromatographic mobilities, their amino acid composition and their behaviour in the Offord plot[12]. Peptides of > 10 amino acid residues were further fragmented by secondary enzymatic digestion and the isolated fragments characterised as above. Amino acid substitutions indicated in the resulting proteolytic fragments were localised by manual dansyl-Edman degradation and/or by degradation with leucine aminopeptidase and carboxypeptidase Y. A full description of the actin sequence methodology is presented elsewhere[5].

Figure 1 shows the complete amino acid sequence of *Physarum* actin. The order of the tryptic and thermolytic peptides in the actin polypeptide chain is based on homology with the rabbit skeletal muscle actin sequence[13]. The polypeptide chain contains 375 amino acid residues although the numbering system indicates only 374. This is because a serine residue following residue 234 has been found in all cytoplasmic actins so far studied[5,14] and has probably been overlooked in the original rabbit skeletal muscle actin sequence[13,14]. To avoid renumbering of the previously documented amino acid exchange past this residue, we agree with the proposal[14] to indicate this residue as serine 234a.

Table 1 summarises those amino acid exchanges which differentiate *Physarum* actin (Fig. 1) from mammalian cyto-

Fig. 1 Amino acid sequence of actin from plasmodium of *Physarum polycephalum*. X indicates a blocking group which is probably the acetyl group found in other actins[15]. His$^{\tau\mathrm{Me}}$ is N^{τ}-methylhistidine. For methods on sequence determination, see ref. 5 and text. Residues which are underlined differ from the corresponding amino acid residue in mammalian γ-cytoplasmic actin[5]. Alignment of the *Physarum* actin peptides was based upon comparison with the rabbit skeletal muscle actin sequence[13].

357	Ser		Ser	Thr
359	Gln		Glu	Gln
364	Ser		Ser	Ala

Data on the amino acid sequences of the mammalian cytoplasmic actins are taken from previous studies[5,10], those for rabbit skeletal muscle actin are derived from ref. 13 with minor corrections[5,14]. Amino acid residues given in separate columns for the mammalian cytoplasmic actins are found in the β and γ forms, respectively[5,10]. The numbering system using 234a is taken from ref. 14 (see also ref. 5 and text).

* Residues underlined indicate the 17 positions where *Physarum* actin differs from mammalian γ cytoplasmic actin.

† Residues underlined indicate the 25 positions where mammalian skeletal muscle actin differs from mammalian cytoplasmic actin.

plasmic actins[5] and from rabbit skeletal muscle actin[13], with the latter sequence containing the few minor corrections recently proposed[5,14]. Like all other actins, *Physarum* actin contains 3-methylhistidine at position 73. We have not been able to detect *N*-methyllysine residues in *Physarum* actin, although they have been reported to occur in *Acanthamoeba* actin[15].

The results presented in Table 1 indicate the strict conservation of the actin structure during evolution. *Physarum* actin and mammalian γ-cytoplasmic actin differ in only 4% of their primary structure (see the 17 positions indicated in Table 1). Comparison with rabbit skeletal muscle actin reveals 8% differences. We previously reported a 7% difference in primary structure in the comparison of mammalian cytoplasmic actins and skeletal muscle actin[5] (see the 25 positions indicated in Table 1). Beyond the six N-terminal residues which are highly variable in all actins so far studied[10,16], *Physarum* actin differs from mammalian cytoplasmic actins in only 12 residues out of a total of 369 residues (a difference of approximately only 3.2%). As was the case for different mammalian actins[5,10,16], the few amino acid exchanges involving charged residues are concentrated in the far N-terminal region of the actin polypeptide chain. In addition, however, *Physarum* actin shows a single Gln→Glu substitution (residue 359) past the first four N-terminal residues. The partial sequence data[4] on *Acanthamoeba* actin indicate another rare substitution involving a charged residue, that is, residue 228 shows an Ala→His exchange. As *Physarum* actin is characterised by a Gln in this position, it seems possible that this residue is rather variable. In the remainder of the currently available sequence data *Acanthamoeba* actin (ref. 4 and Elzinga cited in ref. 2) and *Physarum* actin are rather similar and so far only five amino acid substitutions (residues 76, 103, 106, 228 and 359) have been found.

Physarum actin differs by isoelectric focusing analysis from mammalian cytoplasmic β and γ actins and behaves very similarly to skeletal muscle actin (α-actin)[9]. The sequence data support this result in general, as Glu 359 gives for *Physarum* actin and skeletal muscle actin the same total number of acidic and basic amino acid residues, whereas the more basic mammalian cytoplasmic actins show one less acidic residue (for a discussion of isoelectric points of different actins see refs 5–7, 10). However, we stress that skeletal muscle actin has one more aspartic acid residue and one less glutamic acid residue than *Physarum* actin. Therefore, one could expect a slightly higher isoelectric point for *Physarum* actin, whereas a slightly lower isoelectric point is found experimentally. We cannot explain this small difference, although it could be due to some subtle influence by amino acid changes next to some charged residues, or to the interruption of the four continuous acidic residues at the N-terminus of muscle actin on transition to *Physarum* actin.

The amino acid sequences of several actins from higher vertebrates[5,10] together with the sequence of *Physarum* actin explain why several antiactin antibodies show no species specificity and cover species as divergent as man and *Dictostelium*[17] or *Physarum* (K.W., unpublished observation).

Are the 17 observed amino acid exchanges between *Physarum* actin and mammalian cytoplasmic actin functionally important or are they solely the result of evolutionary drift? Studies by Korn *et al.*[2,18] show that the vertebrate cytoplasmic F-actins differed from the *Acanthamoeba* F-actin in their ability to activate the Mg^{2+} ATPase of rabbit skeletal muscle heavy meromyosin. Thus, our working hypothesis is that some of the amino acid exchanges found between *Physarum* and mammalian cytoplasmic actins will have an important role in the interaction between actin and myosin. Future experiments are aimed at the identification of these residues.

We thank Dr Hinssen, for the plasmodia of *Physarum polycephalum* which made this work possible and Magda Puype for technical assistance. Bromodeoxyuridine mutagenesis in mammalian cells is stimulated by thymidine and suppressed by deoxycytidine

THE most widely accepted explanation for the mutagenicity of 5-bromodeoxyuridine (BUdR) is that mutations occur as the result of occasional mispairing of the analogue during DNA replication[1,2], although the correlation between mutagenesis and the amount of bromouracil (BU) incorporated into DNA has been questioned[3,4]. We have previously shown that BUdR mutagenesis in Syrian hamster cells (measured by the induction of ouabain-resistant (OB^r) or 6-thioguanine-resistant (TG^r) mutants) is determined by the concentration of BUdR in the medium rather than the amount of BU in DNA[5]. This suggested that BUdR nucleotides are involved in BUdR mutagenicity in mammalian cells[5] (see also ref. 4). BUdR triphosphate (BUdRTP) inhibits the ribonucleotide reductase-catalysed reduction of cytidine diphosphate to deoxycytidine (CdR) diphosphate[6], as does thymidine (TdR) triphosphate (dTTP)[7,8]. Therefore, we have investigated the effects of CdR and TdR on BUdR mutagenesis, and report here that the former suppresses and the latter stimulates this process.

The cell lines used have been previously described. RPMI 3460 is a pigmented Syrian hamster melanoma line[9], and HAB-2E is a line derived from 3460 by selection for viability with all the thymine residues in nuclear DNA replaced by BU[5,10]. Most of the experiments were carried out with HAB-2E cells and OB^r as the marker for mutagenesis. Table 1 (expt 1) shows that the addition of 1 μM CdR decreased BUdR mutagenicity and that the maximum decrease was obtained with 10 μM CdR. The addition of 10 μM CdR also decreased BU incorporation into DNA (BU substitution), presumably due to the intracellular conversion of the CdR to TdR nucleotides[12]. However, the maximum suppression of mutagenicity was observed when the CdR concentration was increased from 3 to 10 μM, over which range there was no change in BU substitution. Similar results were obtained (Table 1, expt 2) in the presence of aminopterin, which completely blocks the conversion of CdR to TdR nucleotides[12]. Thus, CdR suppresses BUdR mutagenicity without being converted to TdR nucleotides and without altering the amount of BU in DNA.

Table 1 Suppression of BUdR mutagenesis by CdR

Aminopterin	Additive (μM) BUdR	TdR	CdR	BU substitution (%)	Mutant frequency
Expt 1					
–	–	30	–	–	<0.5
–	30	–	–	72.3	349

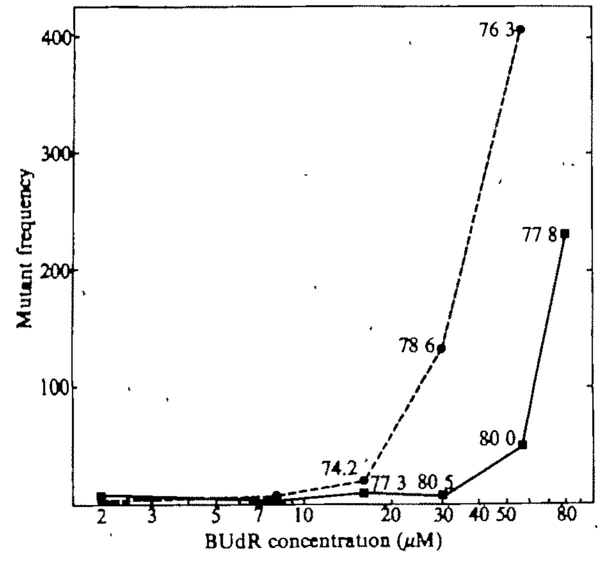
HAB-2E cells were maintained routinely in Dulbecco's modified Eagle's medium supplemented with 10% fetal calf serum (E medium). For mutagenicity assays, Falcon plastic tissue culture flasks (75 cm^2) were inoculated with 5×10^5 cells in 10 ml of E medium containing the indicated additives When aminopterin was used, it was present at 0.4 μM and 0.1 mM hypoxanthine was also added. At 3 and 6 d after inoculation, the medium was renewed with 50 ml fresh medium containing the same additives. After 1 week in BUdR-containing medium, the cells were collected and flasks (75 cm^2) were reinoculated with 5×10^5 cells in 10 ml of E medium containing 0.1 mM hypoxanthine and 16 μM TdR (HT medium). They were cultured in HT medium for 1 week to allow the expression of induced mutations, and then collected and tested for drug resistance. Cells were protected at all times from exposure to light with wavelengths below 550 nm (ref. 11), because of the increased photosensitivity of cells with BU-substituted DNA. During the exposure of cells to BUdR for mutagenesis, the level of BU incorporated into nuclear DNA was determined as previously described[5]. The amount of BU in DNA is expressed as 'BU substitution', defined as the % of thymine residues in nuclear DNA replaced by BU. The results are the mean of four determinations per sample; the s.e.m was generally $< \pm0.5$. The frequency of OB^r mutants was determined by inoculating 3–5 tissue culture dishes (150 mm diameter) each with 10^6 cells in E medium containing 0.9 mM OB. Plating efficiencies were determined by inoculating 3 dishes (60 mm diameter) each with 250 cells in E medium alone. Seven or eight days after inoculation, the dishes were fixed with methanol and stained with Giemsa for colony counting. The mutant frequencies are expressed as the number of OB^r colonies per 10^6 cells and are corrected for the plating efficiency of the cells in the absence of OB. ND, not determined.

Fig. 1 Effect of BUdR concentration on the suppression of mutagenicity by CdR. HAB-2E cells were grown in E medium containing 0.1 mM hypoxanthine and 0.4 μM aminopterin, plus BUdR and TdR in a 4 : 1 ratio. The cells were grown either in the presence (■) or absence (●) of 200 μM CdR. The frequency of OB^r mutants was determined and expressed as described in Table 1. The numbers next to the data points indicate the levels of BU substitution for those points, as described in Table 1.



The effect of increasing the BUdR concentration in the presence of a fixed concentration of CdR was also determined (Fig. 1). HAB-2E cells were exposed to BUdR and TdR in a 4 : 1 ratio in the presence of aminopterin. In the absence of CdR, BUdR mutagenicity occurred when the BUdR concentration exceeded 10 μM. However, in the presence of CdR, BUdR mutagenicity did not occur until the BUdR concentration exceeded 30 μM. The increase in mutant frequency with increasing BUdR seemed to occur at approximately the same rate in the presence of CdR as in its absence, although at higher BUdR concentrations. Apparently, a 2.5-fold increase in BUdR concentration is sufficient to overcome the suppression of mutagenicity by CdR completely. Note that none of these effects was associated with changes in BU substitution.

As dTTP, like BUdRTP, can perturb CdR metabolism, the effects of TdR on BUdR mutagenicity were tested. Table 2 (expt 1) shows that the addition of 10 μM TdR to 10 μM BUdR (a

0028-0836/78/0276—0722$01 00

relatively nonmutagenic concentration) increased the frequency of mutants while decreasing BU substitution. The addition of 100 μM TdR resulted in a similar stimulation of mutagenesis, even though the BU substitution dropped to a very low level. In addition, the stimulation by TdR was suppressed by CdR. Table 2 (expt 2) shows that TdR was also stimulatory to mutagenesis in the presence of aminopterin. CdR again suppressed not only BUdR mutagenicity but also TdR stimulation, and the CdR effects were not associated with changes in BU substitution. Because TdR stimulated mutagenesis, the mutagenicity of TdR alone was tested, but, up to 700 μM, was nonmutagenic (Table 2, expt 1). (The demonstration that TdR stimulated BUdR mutagenesis in these cells is at variance with studies on prokaryotes, in which thymine suppresses BU mutagenesis.)

Table 2 Stimulation of BUdR mutagenesis by TdR

HAB-2E cells were assayed for mutagenicity as described in Table 1, as are methods for determination of BU substitution and mutant frequency.

Experiments were carried out, using resistance to 18 μM TG as the marker, to determine whether the above results were applicable to mutations other than OB^r. Experiments were also carried out using the parental melanoma line 3460, to determine whether the above conclusions were applicable to wild-type cells as well as HAB-2E. The results of these experiments agreed completely with those described above (data not shown).

The results presented above suggest that interactions involving small molecules play a central part in BUdR mutagenesis in mammalian cells. We have shown that (1) CdR suppresses BUdR mutagenicity, (2) CdR suppression can occur without the conversion of CdR to TdR nucleotides and without any change in the amount of BU in DNA, (3) TdR stimulates the mutagenicity of BUdR, while decreasing the amount of BU in DNA, and (4) the stimulation by TdR is suppressed by CdR. These results were observed for two markers of mutagenesis and for two cell lines.

The molecular mechanisms underlying the effects of CdR and TdR on BUdR mutagenesis remain to be elucidated. However, both BUdRTP and dTTP inhibit the ribonucleotide reductase-catalysed reaction which generates CdR nucleotides. Thus, BUdR mutagenicity in mammalian cells, and its enhancement by TdR, may involve the perturbation of CdR metabolism. As mutagenesis can occur even in the presence of very high concentrations of CdR, the results cannot be explained by simple CdR starvation. In addition, as TdR by itself is not mutagenic, it seems that simply perturbing CdR metabolism in the absence of BUdR does not cause mutations. (Our results do not agree with a recent report of mutagenicity by TdR alone[13].) Apparently, some BUdR is necessary to TdR stimulation of mutagenesis to occur, but only a relatively small amount of BUdR is sufficient.

One possible mechanism for the role of CdR metabolism in BUdR mutagenesis is that mutagenesis could involve an 'error-prone' repair system[14] induced by the perturbation of CdR metabolism. It is also possible that altered CdR metabolism could cause an increased error frequency during DNA replication, due to allosteric changes in DNA polymerase itself (compare ref. 4) or to an imbalance of the deoxyribonucleoside triphosphates[13,15]. Although our results demonstrate that BUdR mutagenicity involves effects at sites outside DNA, they do not indicate whether there must also be some BU present in DNA to act as a substrate for any mutagenic functions induced.

Stimulation of DNA synthesis by tumour promoter and pure mitogenic factors

12-*O*-TETRADECANOYL PHORBOL-13-ACETATE (TPA), a potent tumour-promoting agent, stimulates the proliferation of various cell types, including fibroblasts, in cell culture (see ref. 1 for review). Recent studies have demonstrated that there is a close correlation between the potency of phorbol esters for promoting skin tumours and their ability to stimulate DNA synthesis in cultured cells[2]. The growth-stimulating activity of TPA is completely dependent on the presence of serum in the nutrient medium. This requirement for serum has been demonstrated in cultures of mouse epidermal cells[3] and fibroblastic cells[4,5]. The role of serum in the cellular response to TPA remains unresolved. We report here that serum can be replaced by polypeptide hormones like epidermal growth factor (EGF)[6], and insulin and by the growth factor isolated from the conditioned medium of SV40 BHK cells (fibroblast-derived growth factor, FDGF)[7]. Low concentrations of TPA and the growth-

0028-0836/78/0276—0723$01 00

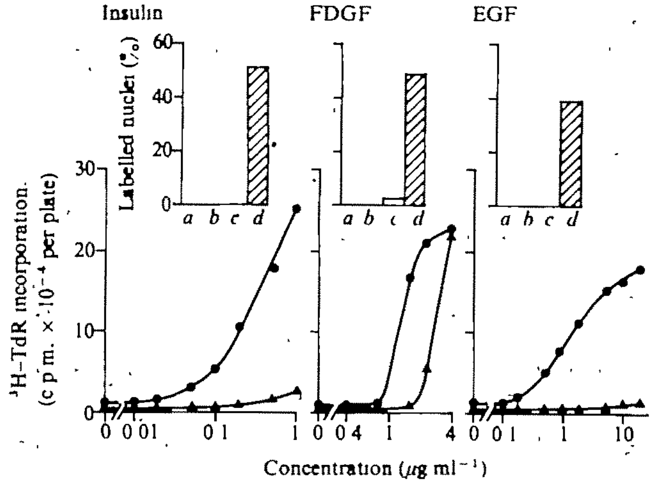

Fig. 1 Effect of insulin, FDGF or EGF on DNA synthesis in the absence (▲) or in the presence of 0.1 μg ml^{-1} TPA (●). Cultures were exposed to the peptide with or without TPA in 2 ml of a 1:1 mixture of Dulbecco's modified Eagles' medium (DMEM) and Waymouth's[14] medium containing ^{3}H-TdR (0.5 μCi ml^{-1}; 0.5 μM). After 40 h at 37 °C, the radioactivity incorporated into acid-precipitable material was measured as previously described[15] (10% foetal calf serum produced ^{3}H-TdR incorporation of 26.5 × 10^4, 27.5 × 10^4 and 30.7 × 10^4 c.p.m. respectively, for the experiments involving insulin, FDGF and EGF). All points are the average of duplicate plates. Stock 3T3 cells were passaged at 3-d intervals in DMEM containing 10% foetal calf serum–100 U ml^{-1} penicillin and 100 ng ml^{-1} streptomycin in a humidified 10% CO_2 atmosphere at 37 °C. In all experiments, cell suspensions were plated in 30-mm Nunc dishes in DMEM supplemented with 10% foetal calf serum, re-fed with the same medium after 3 d, and kept for at least a further 5 d. The cultures of 3T3 cells used were arrested in the G_1/G_0 phase of the cell cycle. The cultures were washed twice with DMEM at 37 °C to remove residual serum immediately preceding the experiment. Bovine insulin 26 IU mg^{-1} was obtained from Sigma; EGF was supplied by Dr S. Cohen, and FDGF was isolated and purified from the medium conditioned by SV40 BHK cells as described previously[7]. TPA was obtained from Consolidated Midland Corporation (Brewster, New York). Stock solutions of 10 mg ml^{-1} TPA were made up in acetone and kept at −20 °C. Equivalent concentrations of acetone were used in all controls. Insets: The experimental conditions were as described above except that the DMEM/Waymouths medium contained ^{3}H-TdR (5 μCi ml^{-1}; 0.2 μM) and the cultures were fixed for autoradiography as described previously[15]. The bars represent the percentage of nuclei incorporating the ^{3}H-TdR: *a*, no addition; *b* 100 ng ml^{-1} TPA, *c*, peptide; *d*, 100 ng ml^{-1} TPA + peptide. The concentrations of insulin, FDGF and EGF were 1 μg ml^{-1}, 1.8 μg ml^{-1} and 10 ng ml^{-1} respectively. Foetal bovine serum produced 79%, 79% and 89% autoradiographically labelled nuclei respectively, in the experiments involving insulin, FDGF and EGF.

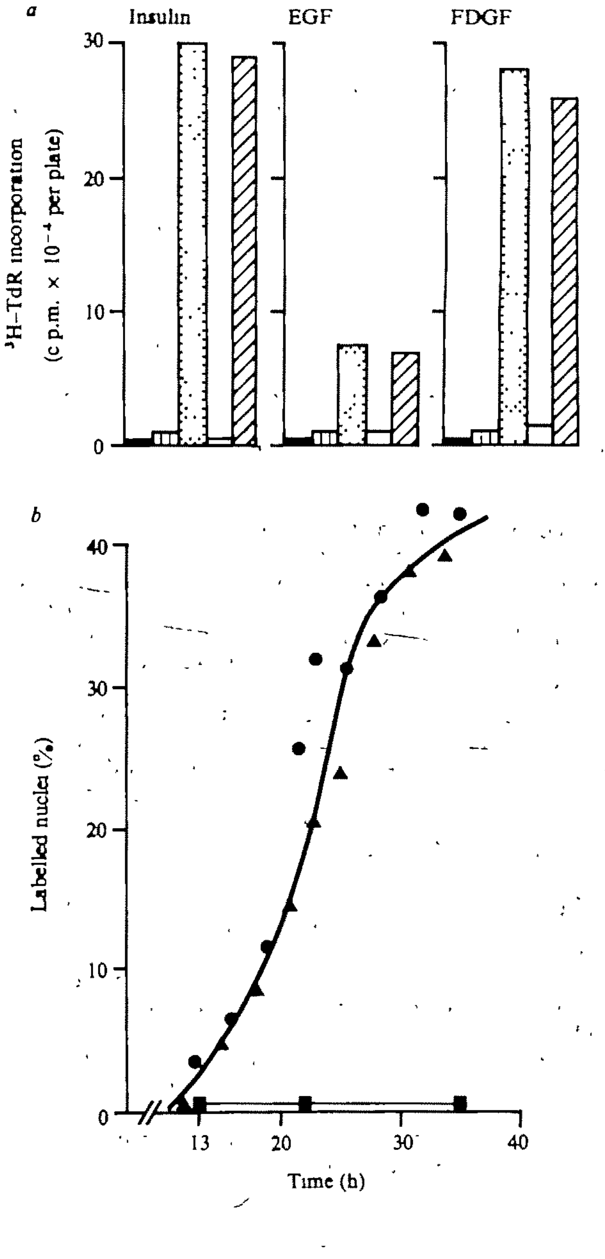
factors stimulate DNA synthesis in quiescent cultures of mouse and human cells in completely serum-free medium.

Figure 1 shows that TPA interacts synergistically with insulin, EGF and FDGF in stimulating ^{3}H-TdR incorporation into acid-precipitable material by quiescent cultures of 3T3 cells. The effects are obtained in entirely synthetic, serum-free medium. The interaction between the tumour promoter and EGF or insulin is particularly striking, because neither of these substances produces a substantial stimulation of DNA synthesis by itself. EGF and TPA reproducibly gave a considerable increase in DNA synthesis in eight independent experiments although the magnitude of the increase varied. The inserts in Fig. 1 show that similar results are obtained when the percentage of labelled nuclei incorporating ^{3}H-TdR was measured, instead of the total ^{3}H-TdR incorporation. In the presence of a fixed concentration of insulin, TPA stimulates DNA synthesis in a dose-dependent manner (results not shown). The lowest

Fig. 2 Effect of sequential incubation of TPA and growth-stimulating factors on DNA synthesis in quiescent 3T3 cells. *a*, Quiescent cultures of 3T3 cells were produced as in Fig 1. Continuous incubations were washed eight times in DMEM at 37 °C before the experiment. Black bar, cultures were incubated continuously in 200 ng ml^{-1} TPA for 40 h; vertical striped bar, cultures were incubated continuously in peptide for 40 h; dotted bar, cultures were incubated for 40 h with 200 ng ml^{-1} TPA and peptide; plain bar, cultures were washed twice with DMEM at 37 °C, incubated 20 min with hormone, washed six times in DMEM at 37 °C and incubated for 40 h with 200 ng ml^{-1} TPA; oblique striped bar, cultures were washed twice in DMEM at 37 °C, incubated 20 min with 200 ng ml^{-1} TPA, washed six times in DMEM then incubated for 40 h with hormone. The final incubation for all cells was in 2 ml 1:1 Waymouths–DMEM containing ^{3}H-TdR (0.5 μCi ml^{-1} 0.5 μM). Incorporation of ^{3}H-TdR into acid-precipitable material was measured as in Fig. 1. Concentrations of peptides were insulin 1 μg ml^{-1}, FDGF 0.7 μg ml^{-1}, EGF 10 ng ml^{-1}. *b*, Percentage of nuclei labelled autoradiographically after continuous incubation with TPA and insulin (●), TPA or insulin alone (■), or by two washes with DMEM at 37 °C followed by 20 min incubation with TPA, six washes of DMEM at 37 °C, and then incubation with 1 μg ml^{-1} insulin (▲). All continuous incubations were washed eight times at the start of the experiment. The final incubation of all cultures was in 2 ml of 1:1 Waymouths–DMEM containing ^{3}H-TdR (5 μCi ml^{-1} 0.2 μM). All points are in duplicate. Autoradiography was performed as described previously[15]. 10% serum produced 86% labelled nuclei at 35 h



concentration of TPA needed to show synergism consistently with 1 μg ml^{-1} insulin was 5 ng mg^{-1}. In contrast to the effect of TPA, phorbol itself, tested either in the absence or presence of insulin, was completely inactive in stimulating DNA synthesis. The close analogue, 4-*O*-methyl-12-*O*-tetradecanoyl-phorbol-13-acetate, was slightly mitogenic (18% of the maximal effect of TPA with insulin) at high concentrations (1 μg ml^{-1}) and in the presence of 1 μg ml^{-1} insulin.

An interesting feature of the synergistic interaction between TPA with insulin is that a brief exposure (20 min) to the promoter was sufficient to render the cultures sensitive to the mitogenic effect of insulin, EGF or FDGF (Fig. 2*a*). Although the effect of TPA persisted even after thorough washing of the cell monolayer (six times with DMEM at 37 °C), it is not known whether the promoter binds to the cultures in a non-washable manner of whether it causes a lasting change in the culture[8]. Brief exposure of cultures to insulin, EGF or FDGF did not result in their becoming sensitive to the effects of TPA (Fig. 2*a*).

Table 1 Synergistic interaction between TPA and insulin on DNA synthesis by quiescent cultures of human embryo lung fibroblasts and 3T6 cells

	Cell type	
	Human embryo lung fibroblasts	3T6
No addition	4.2%	1.7%
10 ng ml^{-1} TPA	7.0%	27.0%
100 ng ml^{-1} insulin	3 6%	8 3%
10 ng ml^{-1} TPA + 100 ng ml^{-1} insulin	22.0%	72.0%

Swiss 3T6 cells were maintained in DMEM containing 10% fetal calf serum and subcultured at 3-d intervals. Quiescent cultures in 30-mm dishes were obtained as previously described[16] Experimental conditions for autoradiography were as in Fig. 1. Primary cultures of human lung embryo lung fibroblasts (provided by Dr F. Balkwill), were maintained in 10% fetal calf serum 90% RPMI 1640 and subcultured once every 7 d. For the above experiment, with 7th passage cells, cells were subcultured into 30-mm plates containing RPMI 1640 supplemented with 0.5% foetal calf serum depleted by 7-d incubation with parallel cultures of human embryo fibroblasts, and left for 5 d They were then washed twice and left in serum-free RPMI 1640 for 4 d. Cells were incubated at 37 °C in RPMI 1640 containing ^{3}H-TdR (5 μCi ml^{-1} 0.2 μM) and different additions for 40 h. Autoradiography was carried out as in Fig 1.

In 3T3 cells, TPA and insulin stimulated-DNA synthesis after a lag of approximately 13 h (Fig. 2*b*). Addition of whole serum stimulated DNA synthesis after a similar lag. The time course of DNA synthesis produced by brief exposure to TPA followed by washing and insulin addition is similar to that produced when insulin and TPA are incubated continuously with the cells (Fig. 2*b*).

The striking synergistic interaction between growth-promoting polypeptides and TPA was also observed when cell multiplication was monitored over a period of several days (Fig. 3). In these experiments, a certain amount of depleted serum (see legend to Fig. 3) was required to prevent cell detachment. Neither TPA nor insulin added to such cultures caused a substantial increase in growth, however, both insulin and TPA together caused a 2–3-fold increase in cell number. Similarly, although EGF and insulin together caused a two-fold increase in cell number, the addition of the tumour promoter with both insulin and EGF resulted in four-fold increase in cell number.

The synergistic interaction between insulin and tumour promoters was also observed in quiescent cultures of early passage human embryo fibroblasts as well as murine 3T6 cells (Table 1). Insulin potentiated the effect of low concentrations of TPA in both cell types. TPA tested at higher concentrations (100–300 ng ml^{-1}) produced a substantial increase in the labelling index of both cell types (results not shown).

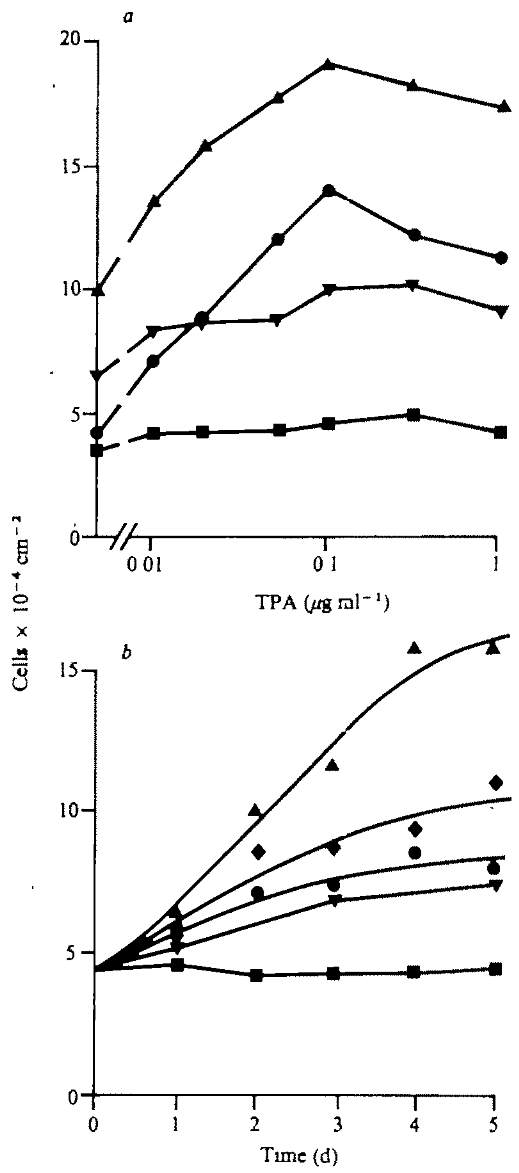


Fig. 3 Effect of insulin, EGF and TPA on cell density when added to quiescent cultures of Swiss 3T3 cells. Culture conditions were as in Fig. 1. Medium from parallel cultures was removed and one-third its volume of Waymouth's medium added to replace low molecular weight nutrients that might have become depleted TPA, insulin and EGF were then added to give final concentrations as in the figures Cell number determinations were made on duplicate plates For each culture, two aliquots of cell suspension, produced by thorough trypsinisation were counted on a Coulter counter. *a*, Effect of different concentrations of TPA on cell density after 5 d of exposure in the absence (■) or in the presence of (▼) 10 ng ml^{-1} EGF; (●) 1 μg ml^{-1} insulin, (▲) 10 ng ml^{-1} EGF and 1 μg ml^{-1} insulin Initial cell density was 4.0×10^4 cells cm^{-2} *b*, Time course of the effect on cell density produced by addition of: (■) 200 ng ml^{-1} TPA, 1 μg ml^{-1} insulin, or 10 ng ml^{-1} EGF alone, (▼) 10 ng ml^{-1} EGF and 200 ng ml^{-1} TPA; (●) 1 μg ml^{-1} insulin and 200 ng ml^{-1} TPA; (◆) 1 μg ml^{-1} insulin and 10 ng ml^{-1} EGF, (▲) 1 μg ml^{-1} insulin, 10 ng ml^{-1} EGF and 200 ng ml^{-1} TPA together. Initial cells density was 4.4×10^4 cells cm^{-2}.

The present experiments indicate that there is a striking synergistic interaction between TPA and growth factors in stimulating DNA synthesis in quiescent cultures of mouse and human fibroblasts maintained in serum-free medium Chemically defined conditions are not only of importance for the study of the mechanism of action of TPA, but may also provide more reproducible assay conditions to screen for tumour promoters or anti-tumour promoters than systems using serum[2,13]. Our findings raise interesting questions regarding other important cellular effects of phorbol ester. It is now reasonable to ask whether in enhancing the expression of the transformed phenotype[9,10], or in blocking terminal differentiation in a variety of cell types[11,12], tumour promoters interact with growth-promoting factors added to the medium, present in serum or produced by the cells. Indeed, the possibility that promotion *in vivo* can be induced by an interaction between the promoter and growth factors should receive serious consideration.

Direct resorption of bone by human breast cancer cells *in vitro*

OSTEOLYTIC bone metastases occur frequency in patients with advanced malignancy. Breast cancer, the most common malignant disease of women, metastasises to bone more frequently than to any other organ[1], and over 80% of patients with advanced breast cancer develop bone metastases[2–4]. The cellular and molecular mechanisms of bone destruction in patients with cancer are not clearly understood. It has been postulated that there may be two mechanisms, one which is mediated by osteoclasts and one which occurs independently of osteoclasts[5,6]. We show here that cultured human breast cancer cells have the capacity to resorb directly *in vitro*, independently of osteoclast stimulation.

Supernatant media collected from the human breast cancer cell line MCF-7 (ref. 7) were tested for bone-resorbing activity by culture with live and killed fetal rodent long bones previously incorporated with ^{45}Ca or ^{3}H-proline. The assay system for live bones has been described in detail previously[8,9]. The killed bones were devitalised by overnight exposure to UV light to leave a calcified acellular bone matrix. There is no glucose uptake by these bones and they do not respond to parathormone (PTH) or prostaglandins. Killing the bones allows assessment of the effect of exogenous cells on bone resorption independently of the effects of endogenous bone cells[10]. The bones were labelled with ^{45}Ca or ^{3}H-proline[11] by injection of the mothers 1–3 d before death. Mineral release and matrix resorption were assessed in the same way as for live bones. Experiments on matrix resorption were carried out with mouse bones rather than fetal rat bones because it was easier to incorporate the label into the former, probably because of the smaller volume of distribution of the isotope in the pregnant mice.

Table 1 shows that in three separate experiments supernatants from MCF-7 cell cultures caused the release of previously incorporated ^{45}Ca from live and dead fetal rat long bones. Similar results were obtained when the bones were co-cultured with the MCF-7 cells. Table 2 shows that the bone matrix was also resorbed by the MCF-7 cells and their conditioned media. In these experiments we determined the proportion of the radioactivity released into the media from the bones which was in the form of ^{3}H-hydroxyproline, because this latter component reflects bone collagen breakdown[11]. Media from individual bone cultures were pooled before chromatography on a Dowex column so that standard errors could not be calculated. There was very close agreement between the data obtained from release of total radioactivity and the data obtained from release of ^{3}H-hydroxyproline (Table 2).

Table 1 Effects of supernatant media from cultured human breast cancer cells (MCF−7) on mineral release from live and dead fetal rat long bones compared with paired bones treated with control media

Bones	^{45}Ca Release (treated /control ratios) Expt *A*	Expt *B*	Expt *C*
Live	1.39±0.13*	1.75±0.06*	1.96±0.10*
Dead	1.59±0.06*	1.41±0.09*	1.77±0.03*

MCF−7 cells were grown in monolayer culture in Dulbecco's modified Eagle medium (Gibco) with 10% heat-inactivated fetal calf serum. Cell-free supernatants were collected from cultures which were near confluency. The assay for bone resorption is based on the release of previously incorporated ^{45}Ca from fetal rodent long bones in organ culture[8,9]. Bone-resorbing activity was quantitated as the ratio of ^{45}Ca released into the media by test bones compared with ^{45}Ca released into the media from paired bones cultured in control media. Each bone was cultured for 48 h with 0.5 ml of media from the MCF-7 cultures. Values are means ±s.e.m. for 4 pairs of bone cultures.

*Significantly greater than 1.0, $P < 0.05$.

Table 3 shows that the supernatants from four other established breast cancer cell lines caused mineral release from devitalised fetal rat bones. Other normal and neoplastic cells had no effect on bone mineral release. The effects of MCF-7 cells on bone could not be ascribed to changes in *p*H. Resorption occurred in experiments where there was no change in the measured *p*H of the media, and also when the *p*H of the supernatant media was readjusted to 7.4 before the bones were cultured in the cell-free media.

Fig. 1 Effects of pharmacological inhibitors of osteoclast activity on bone resorption due to human breast cancer cells (MCF-7) and prostaglandin-E_2 (10^{-7} M). The bone-resorbing effects of the MCF-7 supernatants were not altered by cortisol (10^{-6} M) or phosphate (6 mM). In contrast, PGE_2-mediated bone resorption was inhibited by these drugs. Bone resorption is measured as per cent increase in ^{45}Ca release from bones cultured with MCF-7 culture supernatants or PGE_2 compared with paired bones cultured in identical media except for the MCF-7 supernatant or PGE_2. *a*, MCF-7; *b*, MCF-7 + phosphate; *c*, MCF-7 + cortisol; *d*, PGE_2; *e*, PGE_2 + phosphate; *f*, PGE_2 + cortisol.

Table 2 Effects of cultured human breast cancer cells (MCF-7) on matrix resorption of live and dead fetal rodent long bones labelled with ^{3}H-proline

Bones	Total radioactivity released (treated/control ratios)*	^{3}H-hydroxyproline released (treated/control ratios)
Live		
MCF-7 supernatants	1.67±0.10†	1.65
PTH (400 ng ml^{-1})	1.74±0.04†	1.75
Dead		
MCF-7 cells	2 26±0.26†	2.0
MCF-7 supernatants	1.38±0.09†	1.24

Fetal bones were labelled with ^{3}H-proline by injection of the mother 2 d and 1 d before death. Each bone was cultured with 0.6 ml media. At the end of the culture period, 100-μl aliquots of this media were removed and counted in a liquid scintillation counter so that treated-to-control ratios for total radioactivity released from pairs of bones could be obtained. The remaining media for each treatment group were pooled and applied to a Dowex column to separate ^{3}H-hyroxyproline from ^{3}H-proline[20]. All the radioactivity applied to this column was recovered in the fractions corresponding to where markers of proline and hydroxyproline were eluted. The duration of the bone cultures was 2 d. In some dishes, MCF-7 cells were co-cultured with the bones and in others supernatants taken from MCF-7 cultures near confluency were used

*Values are means ±s.e.m. for 4–12 pairs of bone cultures.

†Significantly greater than 1.0, $P < 0\ 05$.

Morphological features of resorbing live bones which were cultured with MCF-7 media were examined and compared with bones cultured with prostaglandin-E_2 (10^{-6}M). The bones which were cultured with prostaglandins showed many giant multinucleated osteoclasts adjacent to the endosteal bone surfaces. These bones were resorbed 80% more than corresponding paired control bones as measured by ^{45}Ca release. Similar features are found when bones are cultured with other humoral stimulators such as PTH, osteoclast-activating factor, active vitamin D metabolites[12], and thyroid hormones[13]. In contrast, bones which were cultured with supernatants from the MCF-7 cultures showed no detectable osteoclasts although there was a similar release of ^{45}Ca (83% increase in ^{45}Ca release compared with corresponding control).

To confirm that osteoclasts are not required for breast cancer cells to resorb bone, live bones were cultured with cortisol (10^{-6} M) and phosphate (6×10^{-3} M), both of which inhibit the effects of osteoclasts on bone[14,15]. Phosphate and cortisol had no effect on bones resorbing in response to MCF-7 media (Fig. 1). On the other hand, prostaglandin-stimulated bone resorption was inhibited in bone cultures to which cortisol or phosphate were also added. These data also indicate that the MCF-7 media resorbed bone independently of osteoclasts.

Prostaglandins could not have played any part in the effects that we have observed. They do not resorb devitalised bone[16], and phosphate and cortisol, which inhibited prostaglandin-stimulated bone resorption, had no effect on MCF-7 supernatants (Fig. 1). We confirmed that bone resorption stimulated by MCF-7 cells occurred independently of prostaglandins by culturing MCF-7 cells with indomethacin (10^{-5} M) on live bones. Indomethacin, which inhibits prostaglandin synthesis at this concentration, had no effect on the release of ^{45}Ca from these lives bones resorbed by the MCF-7 cells (data not shown). The conditioned media from MCF-7 cells do not contain sufficient immunoreactive prostaglandins of the E or $F_{2\alpha}$ types to cause bone resorption in this assay (data not shown).

Although our data show no evidence of osteoclast stimulation by breast cancer cells *in vitro*, this does not preclude a role for osteoclasts in metastasis formation and hypercalcaemia *in vivo*. It is possible that osteoclasts could be stimulated at metastatic sites by factors released by cells other than cancer cells. Local bone-resorbing factors such as prostaglandins[16] or osteoclast-activating factor[17] could be released by monocytes[18], activated lymphocytes[17] or fibroblasts as part of a cell-mediated immune response to the tumour. These effects would not be observed in our experiments.

Every breast cancer cell line that we tested resorbed bone *in vitro* (Table 3). This correlates with the clinical observation that nearly all patients with breast cancer will develop bone metastases if they live long enough with the disease[2–4]. Not all cultured neoplastic cells have this property (Table 3), but more work will be required to determine how frequently tumour cells in culture behave in this way.

Thus, these *in vitro* results suggest that there may be at least two mechanisms for the bone destruction which occurs in patients with malignant disease. Bone destruction may be osteoclast mediated and this is the probable mechanism in patients with myeloma[19] and with solid tumours who develop ectopic hormone syndromes. However, the studies described here show that some cancer cells can resorb bone directly independently of osteoclasts. In some patients it is possible that both mechanisms are relevant[5,6].

This work was supported by grants from the USPHS and the ACS. We thank Elissa Keogh, Mary Ann Kowalski and Monica Gondek for technical assistance, and Drs Lawrence Raisz and Peter Sherline for advice. MCF-7 cells and other human breast

Table 3 Effects of cell culture supernatants on mineral release from devitalised fetal rat long bones compared with paired bones cultured with control media

Cell line	Source	Clinical data	^{45}Ca release (treated/control ratios)
MCF−7	Malignant pleural effusion	Not known	1 42±0 07*
MDA-MB-157	Malignant pleural effusion	Not known	1 34±0 08*
MDA-MB-231	Malignant pleural effusion	Not known	1.54±0.13*
MDA-MB-330	Malignant pleural effusion	Bone metastases	1 43±0.09*
MDA-MB-134	Malignant pleural effusion	Bone metastases	1.35±0.13*
3T3 Cells	Mouse fibroblasts	No abnormality	1.08±0.05
Normal lymphocytes	Human peripheral blood	No abnormality	1.05±0.03
Chronic lymphocytic leukaemia lympocytes	Human peripheral blood	Osteopenia, normal serum calcium	0.96±0.03
Ovarian cancer	Human primary tumour	Hypercalcaemia, no bone metastases	0.99±0.05
Lung cancer	Human primary tumour	Hypercalcaemia, no bone metastases	0.90±0 12
Chondroblastoma	Human primary tumour	No skeletal abnormality	1.02±0.03

The duration of the bone cultures was 2 d. Supernatants were taken from tumour cells and 3T3 cells which were near confluency. The non-adherent lymphocytes were cultured for 2 d at a cell density of 1.5×10^{6} cells ml^{-1} in Dulbecco's modified Eagle medium and 10% fetal calf serum. MCF-7, MDA-MB-157, MDA-MD-231, MDA-MB-330 and MDA-MB-134 are established human breast cancer cell lines. Values are means ±s.e.m. for 4 pairs of bone cultures.

*Significantly greater than 1.0, $P < 0.05$.

cancer cell lines were obtained from E. G. and G. Mason Research Institute.

Selective expression of transduced or cloned DNA in minicells containing plasmid pKB280

DERIVATIVES of coliphage λ, carrying inserts of essentially any prokaryotic or eukaryotic DNA, can now be constructed using novel λ cloning vectors. Often, the reason for constructing these derivatives is to determine the polypeptides encoded by the inserted DNA. Phage expression can be analysed by infection of anucleate *Escherichia coli* minicells in which all host syntheses are absent[1]. However, analysis of the expression of the non-λ DNA insert in this system is complicated by the concurrent expression of λ DNA. Attempts to inhibit the expression of the λ genes by use of minicells from a λ lysogenic minicell-producing strain were unsuccessful, indicating that insufficient λ repressor was segregated into the minicells (Shaw, Epp, Pearson and J.N.R., in preparation). Recently a plasmid, pKB280, was constructed which carries the gene (*c*I) for the λ repressor protein and in which approximately 1% of the soluble protein of *E. coli* strains carrying this plasmid is λ repressor[2]. Minicells produced by a derivative of *E. coli* DS410 carrying plasmid pKB280 have been infected by transducing and cloning phages. We report here that only the non-λ DNA is expressed in these minicells.

E. coli DS410 (pKB280) was constructed by transformation of *E. coli* DS410 with purified plasmid DNA and selection for tetracycline resistance and immunity to λ. The plasmid would be expected to segregate into minicells, so that minicells produced by this strain should synthesise plasmid-encoded polypeptides. Figure 1 shows that minicells from *E. coli* DS410 (pKB280) synthesise large amounts of a polypeptide of molecular weight 26,000, presumably λ repressor, whose molecular weight from amino-acid sequence data is 26,228 (ref. 4). In addition, a further 24 polypeptides are detectable which, together with repressor, would require a total coding capacity of 10,700 base pairs of DNA. Plasmid pKB280 is approximately 6,800 base pairs in length[2,5]. It is clear, therefore, that the observed polypeptides exceed the coding capacity of the plasmid. As all the polypeptides synthesised are smaller than the repressor polypeptide, it seems likely that incomplete forms of repressor and/or proteolytic cleavage of the repressor occur in minicells.

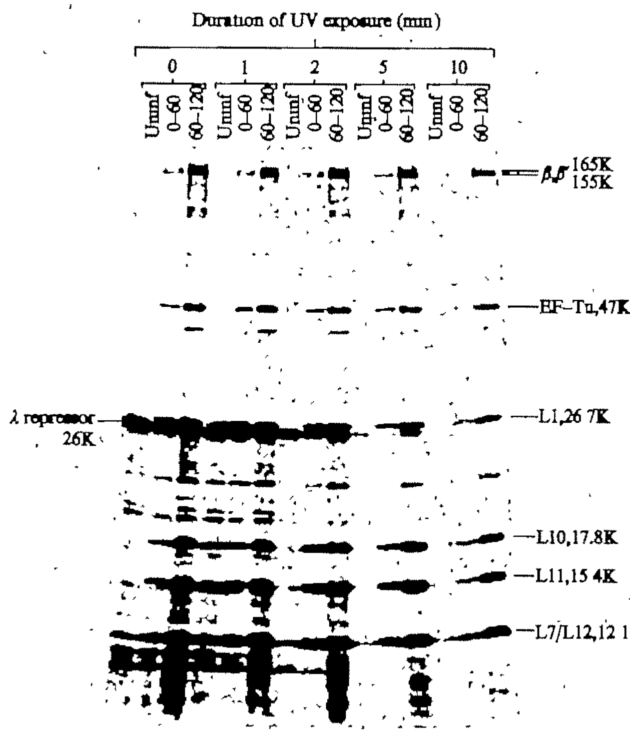

Fig. 1 Autoradiogram of the electrophoretic separation of the polypeptides synthesised in uninfected and λ*rif*^{d}18-infected minicells of *E. coli* DS410 (pKB280). Minicells were prepared as previously described and suspended (2×10^{10} per ml) in M9 minimal salts medium containing 20 μg ml^{-1} D-cycloserine[1,3]. The minicells were exposed to ultraviolet irradiation (290 μW cm^{-2}) for the indicated times. Aliquots of the infected minicells were infected (MOI $\hat{=}$ 5) with λ*rif*^{d}18 phage. Uninfected and infected minicells were incubated at 37 °C in the presence of ^{35}S-methionine assay medium[1,3]. The uninfected minicells and one aliquot of infected minicells (0–60) were allowed to incorporate the radioactivity for 1 h. A second aliquot of infected minicells was incubated in M9 glucose-salts minimal medium for 1 h at 37 °C before addition of ^{35}S-methionine assay medium These samples were then allowed to incorporate radioactivity for 1 h (60–120). Preparation of the radioactively labelled polypeptides synthesised in the minicells for electrophoresis, polyacrylamide gel electrophoresis through 14–20% polyacrylamide gradient gels, impregnation for fluorimetry and production of autoradiograms have been described previously[1,3]

Infection of the minicells by λ*rif*^{d}18 was used to test the function of the λ repressor in minicells. Phage λ*rif*^{d}18 carries the genes for β and β′ subunits of RNA polymerase, for EF-Tu and for the ribosomal proteins L1, L10, L11 and L7/L12 (refs 6–9). Infection results in the synthesis of only non-λ polypeptides encoded by λ*rif*^{d}18 in addition to the plasmid-encoded polypeptides (Fig. 1). No λ genes are expressed, indicating that the repressor inhibits the expression of the λ portion of λ*rif*^{d}18. The minicells were exposed to ultraviolet irradiation before infection, to destroy the synthesising ability of the plasmid (Fig. 1), and subsequent infection by λ*rif*^{d}18 resulted in the synthesis of only the non-λ polypeptides encoded by the phage genome.

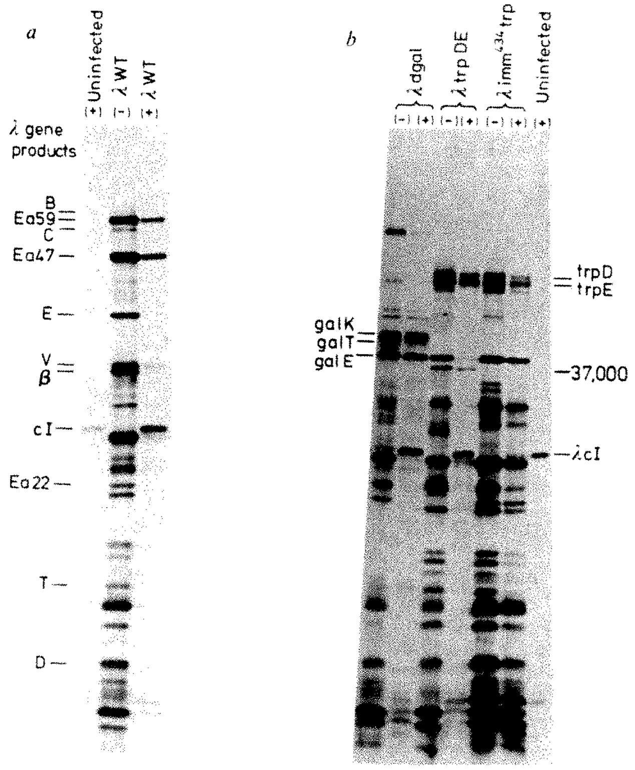
Infection of the repressor-containing minicells by λwt phage results in the synthesis of reduced amounts of only two b2 region non-essential gene products (pEa47 and pEa59 in Fig. 2*a*). These two polypeptides have also been found to be synthesised in infected minicells in the absence of λ N protein (Shaw and J.N.R., unpublished observation). Fortuitously, the genes encoding these polypeptides are usually deleted in transducing or cloning phages, as in the phage λ*dgal*70/4 (ref. 10) shown in Fig. 2*b*. Infection by λ*dgal*70/4 of minicells containing repressor results in the synthesis of only the *gal* operon polypeptides.

There are basically two types of λ-cloning vectors. First, the insertion type in which only one restriction endonuclease site

0028-0836/78/0276—0728$01 00

remains in the vector DNA and which is often located in the *c*I gene itself. Second, replacement vectors which have two restriction sites flanking a replaceable fragment of DNA[11]. Figure 2b shows the result of expression in minicells of an insertion vector (NM607 (ref. 11)) or replacement vector (NM596) which carry the same fragment of cloned DNA, namely the 4.7 megadalton fragment of DNA derived from plasmid VH151 (refs 12, 13) which encodes the *trpDEop* region of the *E. coli* chromosome. The *trpD* and *trpE* gene products can be readily identified from their published molecular weights[14] (Fig. 2*b*). Expression of the λ genes of the replacement vector is inhibited by the high concentration of λ repressor in the plasmid-containing minicells. Only the *trpD* and *trpE* gene products and a polypeptide of molecular weight 37,000 are synthesised in the presence of λ repressor. The 37,000 polypeptide may result from expression of the fusion of part of the *trpC* gene which is also carried on the cloned fragment[13] with the adjoining λ DNA. In contrast to the replacement vector, however, even in the presence of high concentrations of λ repressor, infection of minicells by the phage with the *trpDEop* fragment inserted in the *c*I gene results in the synthesis of polypeptides encoded by both the λ and the cloned DNA. This is exactly what would be expected, because the *c*I gene of this insertion vector, as found for many insertion vectors[11], is not the homologous λ *c*I gene but rather the *c*I gene of the lambdoid heteroimmune phage 434 (ref. 11). Expression is therefore insensitive to λ repressor. A plasmid carrying the immunity region of phage 434 has recently been isolated (A. Bailone and R. Devoret, personal communication). Construction of a minicell strain carrying this plasmid should provide a system in which DNA cloned in i^{434} phages can be selectively expressed.

Fig. 2 Comparison of the polypeptides synthesised in infected minicells in the presence and absence of λ repressor. Minicells were prepared from *E. coli* DS410 (−) and *E. coli* DS410 (pKB280) (+). The minicells were UV irradiated for 8 min (290 μW cm^{-2}) at a concentration of 2×10^{10} minicells per ml. *a*, Minicells infected by λwt ($\lambda c\mathrm{I}_{857}\mathrm{S}_{\mathrm{am}7}$); *b*, minicells infected by λ*dgal* 70/4 (ref. 10); λ replacement vector NM596, nin 5, carrying the *trpDEop* fragment of the *E. coli* chromosome[12,13] between *Eco*RI sites 2 and 3 of λ; λ insertion vector NM607, b_{538}, carrying the *trpDEop* fragment of the *E. coli* chromosome inserted in the *Eco*RI site located in the *imm*^{434} *c*I gene[11]. Infected and uninfected minicells were allowed to incorporate ^{35}S-methionine for 2 h at 37 °C in M9 minimal salts medium. Electrophoretic and other methods were as described in Fig. 1.



In conclusion, it seems possible to use ultraviolet-irradiated minicells produced by *E. coli* DS410 (pKB280) to express exclusively cloned or transduced DNA *in vivo*. The expression requires that the fragment of DNA of interest carries a promoter which is insensitive to λ repressor. Expression of fragments of DNA which do not carry promoters may still be analysed in minicells without λ repressor; however, λ expression will also occur[1]. Comparison of the polypeptides synthesised in minicells containing or lacking repressor infected by vector phage with and without cloned or transduced DNA should enable the following questions to be answered. (1) Are genes on the fragment of DNA expressed in *E. coli*? (2) Does the fragment of DNA carry a promoter which functions in *E. coli*? (3) If (1) is positive, then how many and what are the molecular weights of the encoded polypeptides (or mRNAs), and if (2) is positive, can the expression be affected by the experimental conditions, such as an inducing compared with a non-inducing medium?

I thank Drs J. Little, A. Pühler and W. Klipp for the construction and provision of the *E. coli* DS410 (pKB280) strain and the λ*trpDE* phages, R. Tailor for technical assistance, and J. E. Shaw and K. Trinks for discussions and help with identification of λ and *gal* operon products.

Note added in proof: Minicells from *E. coli* DS410 carrying the plasmid pGY101 (from R. Devoret) which confers immunity to i^{434} phages have been found to function as predicted and permit the selective expression of non-λ DNA contained in i^{434} vector genomes.

Assembly of stratum corneum basic protein and keratin filaments in macrofibrils

THE stratum corneum is the most superficial aspect of mammalian epidermis and consists of several layers of fully differentiated, dead cells filled with an insoluble protein complex called keratin. Early ultrastructural studies of the stratum corneum cells revealed a 'keratin pattern' of light-staining filaments 70–80 Å in diameter embedded in a dark-staining osmiophilic amorphous matrix[1]. The filaments are synthesised in the inner living cell layers and are variously termed tonofilaments, α-keratin or, more accurately, keratin filaments. The subunits of the filaments of both the living cells and stratum corneum have been extracted with dissociating reagents from bovine[2–4], rat[5–6], mouse[7], and human[8] epidermis. In appropriate conditions, these subunits will polymerise *in vitro* into native-type keratin

0028-0836/78/0276—0729$01.00

filaments that are uniformally 70–80 Å in diameter[7,9]. In contrast, the amorphous matrix has not been positively identified at the biochemical level, although it was recently suggested that a stratum corneum basic protein (SCBP) rich in histidine has properties consistent with a possible function as an interfilamentous matrix substance[10]. We show here that highly ordered structures reminiscent of the keratin pattern in the intact stratum corneum form when the SCBP and epidermal keratin filaments are combined *in vitro*.

SCBP was purified from newborn rat epidermis as previously described[10]. The keratin filament subunits were isolated from the same source by a modification of previous techniques[3,5]. Other fibrous proteins were also combined with SCBP in the aggregation experiments. These included: keratin filaments assembled *in vitro* from the subunits extracted from mouse[7], human and bovine[9] epidermis; β-keratin filaments polymerised *in vitro* from the *S*-carboxymethyl derivatives of chicken feather[11]; mouse skin collagen, types I and IV (ref. 12); F-actin isolated from mouse skeletal muscle and mouse epidermal cells grown in culture[13].

The rat epidermal keratin filaments outlined by negative-staining with uranyl acetate are apparently identical to those of other species[7,9]. They are long rods uniformly 70–80 Å in diameter, but in places display a distinct electron-dense central line suggestive of a core (Fig. 1*a*).

When SCBP was combined with these filaments in ratios as low as 0.1 : 1 (by weight), there was an immediate increase in turbidity indicating association of the proteins. At ratios of 0.2 : 1 or greater, easily observable fibrous-like aggregates precipitated from suspension. The amount of aggregate increased with increasing ratios of SCBP to filaments up to about 2 : 1. Under the electron microscope, these aggregates were composed of large numbers of orientated keratin filaments (Fig. 1*b*,*c*). Bundles of filaments in differentiating keratinocytes are termed macrofibrils[16], a term which might also accurately describe these aggregates formed *in vitro*. When formed at low SCBP-to-filament ratios, filaments in the macrofibrils assembled in either a loose or tight organisation but when formed at higher ratios, more compact macrofibrils generally resulted in which filaments were highly aligned and tightly packed. The macrofibrils formed within seconds of mixing and were stable for several days at room temperature and indefinitely at 4°C.

Samples of the macrofibrils were fixed, embedded, sectioned and observed in both longitudinal and cross section. In longitudinal section, lightly stained filaments 70–80 Å in diameter were aligned in close apposition and were separated at an approximately uniform distance by dark-staining material (Fig. 2*b*). In cross section, darkly stained dots were observed surrounded by light haloes. These structures corresponded to the central dense core and the electron-lucent portions of the filament. The diameter of the light halo is identical to the diameter of the filaments seen in longitudinal sections. The filaments, in turn, were outlined by darker-staining material which filled the interfilamentous interstices (Fig. 2*c*). This pattern closely resembles the keratin pattern of certain stratum corneum cells.

Two types of control experiments were performed. Cytochrome *c* and a histone preparation (calf thymus, type II, Sigma) were each tested as alternate basic proteins. When mixed with rat keratin filaments, there was a slight increase in turbidity indicating association of the basic proteins with the anionic filaments, but no macrofibrils formed. The individual filaments were coated with an amorphous layer of protein and, as a result, seemed irregular in diameter. Other filament preparations were also tested. β-Keratin filaments from chicken feather, mouse dermal collagen types I and IV and F-actin from mouse skeletal

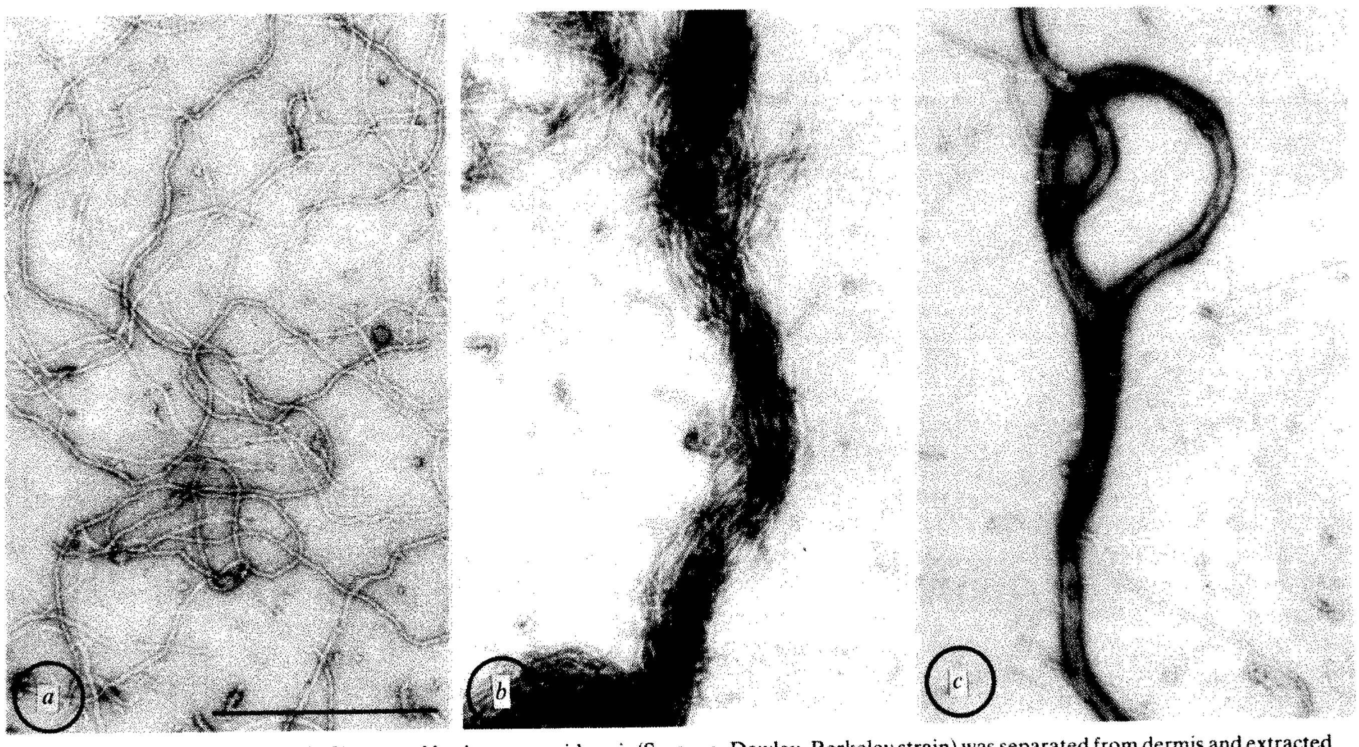

Fig. 1 *a*, Rat epidermal keratin filaments. Newborn rat epidermis (Sprague–Dawley, Berkeley strain) was separated from dermis and extracted first with 1 M potassium phosphate (*p*H 7.0) to remove keratohyalin[14], then with 4 M urea in 0.05 M phosphate (*p*H 7.0) for 3 h at 23 °C and with 8 M urea in 0.1 M Tris-HCl (*p*H 8.5) containing 0.1 M 2-mercaptoethanol for 16 h at 23 °C. All extraction buffers contained the protease inhibitor phenylmethylsulphonyl fluoride. The 4 M urea extract was used to prepare SCBP[10], and the 8 M urea extract was the source of the keratin filament subunits. After further purification by DEAE-cellulose chromatography[15], these subunits (1 mg ml^{-1}) were dialysed against 5 mM Tris-HCl (*p*H 7.6) containing 1 mM dithiothreitol or 25 mM 2-mercaptoethanol for 16 h at 23 °C during which time filaments formed in suspension. For negative staining, filament suspensions were diluted to approximately 0.1 mg ml^{-1}, placed drop by drop onto parlodion and carbon-coated grids, stained with 1% uranyl acetate, dried and examined in a Philips 201 transmission electron microscope (TEM). *b* and *c*, recombination of rat epidermal keratin filaments with SCBP. SCBP and filaments were equilibrated at 1 mg ml^{-1} in 5 mM Tris-HCl (*p*H 7.6). Samples of the two solutions were mixed at an SCBP-to-filament ratio of approximately 0.25 : 1 (by weight), allowed to stand for 5 min, placed drop by drop on grids, negatively stained with uranyl acetate and examined by TEM. *b*, Loose rope-like aggregates of aligned filaments; *c*, compact macrofibrils with highly aligned filaments. Scale bar, 0.5 μm.

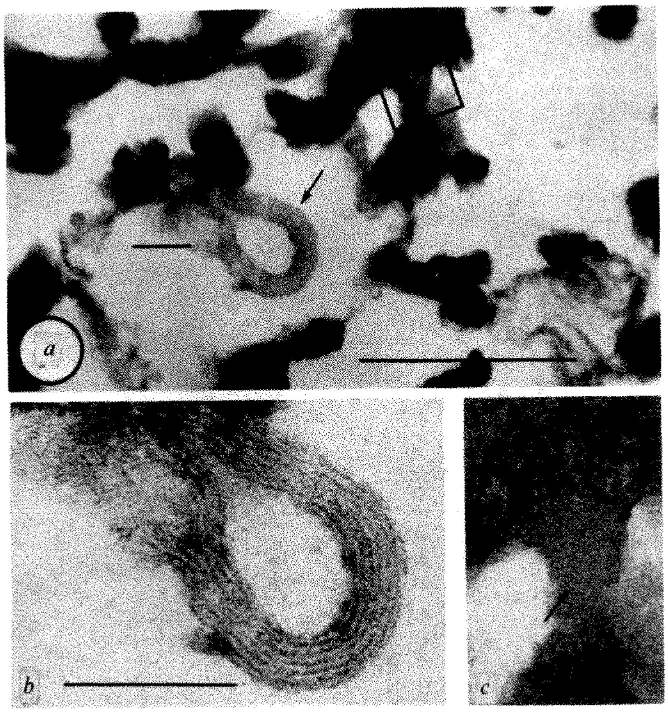

Fig. 2 Ultrastructure of fixed, embedded macrofibrils formed *in vitro* at a ratio of SCBP to filaments of approximately 4:1. Macrofibrils were withdrawn from the tube, fixed for 1 h in half-strength Karnovsky fixative[17], dehydrated through a graded series of alcohols, and embedded in Epon[18]. *a*, Filaments seem to be combined with sparse (arrow) and abundant (box) quantities of SCBP. Scale bar, 0.5 μm. *b*, Aligned filaments in longitudinal section sparsely coated with SCBP. Scale bar, 0.2 μm. *c*, Cross-sectional view of filaments in a large amount of SCBP. Arrows indicate the black dot of the central dense line within the filament. Same magnification as (*b*).

or cultured mouse epidermal cells did not aggregate into fibres or form macrofibrils when mixed with SCBP. In each case, an increase in turbidity was seen on mixing and the fibrous protein was coated in an apparently random manner by the SCBP.

Thus the formation of macrofibrils *in vitro* is specific for SCBP and epidermal α-keratin filaments. This specificity, the highly orientated nature of these structures, and their close resemblance to the structure seen in intact stratum corneum, lead us to conclude that the SCBP may be an interfilamentous or matrix protein of epidermal keratin.

We thank Dr George F. Odland for encouragement and Dr Cliff Murray for mouse skin collagen. This work was supported by USPHS NIDR grants DE 04660 and DE 02600 and NIH grant AM 07019.

Actin microcrystals and tubes formed in the presence of gadolinium ions

SKELETAL muscle actin can be isolated either as a globular monomer, G-actin, or as a filamentous polymer, F-actin[1,2]. The transition of G to F-actin is achieved by the addition of salts of monovalent or divalent cations. In the presence of higher concentrations of divalent cations F-actin filaments further

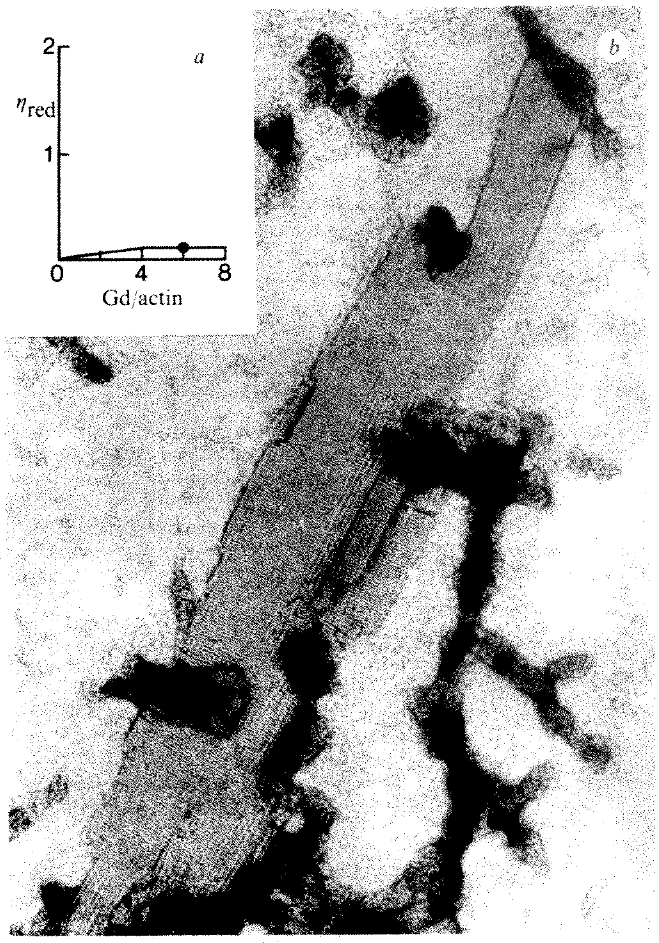

Fig. 1 *a*, Effect of Gd III on the reduced viscosity of actin in the absence of KCl. Reaction conditions are: 0.2 mM ATP; 0.5 mM β-mercaptoethanol; 2 mM PIPES at *p*H 6.95; 25 °C; $GdCl_3$ added at the molar ratios indicated on the abscissa. As Gd III binds to ATP the amount stated was that in excess of the ATP present[8,9]. 1.15 mg ml^{-1} G-actin was prepared from rabbit skeletal muscle by the method of Spudich and Watt[10]. Steady state $\eta_{red} = [(ts/tw) - 1/C$ ml mg^{-1}: where *ts* is the flow time (s) of the sample, *tw* is the flow time of the solvent (31.5 s) and *C* is the G-actin concentration (mg ml^{-1}) as determined by the Lowry method[11]. *b*, Actin microcrystal formed with Gd III in the conditions specified by the black dot in (*a*). The overall dimensions of the polymer are about 1 μm × 0.2 μm. In some experiments microcrystals were formed by adding Gd III slowly by dialysis. Specimens were supported on thin carbon-coated copper grids and negatively stained with 1% uranyl acetate. Magnification was calibrated with the known 14.4-nm repeat of thick filaments of the oyster adductor muscle[12]. ×143,000

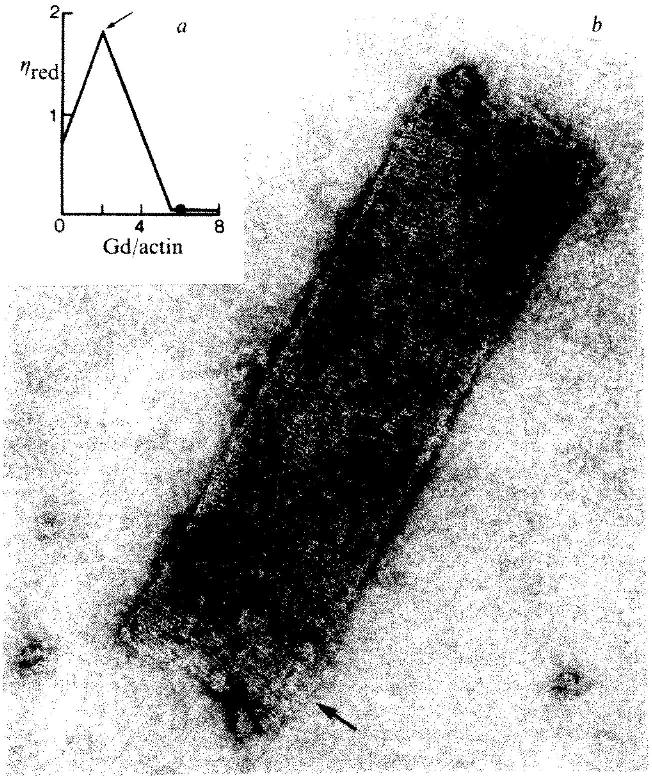
aggregate into paracrystalline arrays[3–6]. We present here evidence for two new types of ordered actin assembly formed in the presence of trivalent lanthanide cations, which are not composed of F-actin filaments.

Recently we have studied the effects of trivalent lanthanides on the viscosity of G-actin in the absence[7] and presence[8] of 0.1 M KCl. These data suggest that amounts of lanthanide ions greater than 5.5 mols per mol of actin cause actin to aggregate into a form different from F-actin. We have now investigated in the electron microscope the aggregates induced by the trivalent lanthanide gadolinium (Gd III). Figure 1*b* shows that without added KCl, Gd III ions cause G-actin to assemble into sheet-like structures which we will refer to as actin microcrystals. These polymers are formed at molar ratios higher than 4 mols Gd III per mol of G-actin. Their dimensions vary but they are usually not longer than 1 μm and not wider than 0.3 μm. There are often sharp steps in the staining density across the structure which suggests that they consist of more than one layer. The microcrystal in Fig. 1*b* is at least three layers thick. They have a prominent axial period of approximately 3.3 nm which is best observed when micrographs are viewed obliquely from the side. A less clear transverse repeat of about 6.0 nm is occasionally seen when the structures are viewed obliquely along their length but this was difficult to measure accurately. Microcrystals differ markedly in appearance from actin paracrystals. In particular they do not show the 36-nm axial repeat characteristic of the long pitched helical repeat of F-actin[3,4]. Some less well-ordered rope-like aggregates of actin can also be seen in Fig. 1*b*, but no individual filaments of F-actin were present in these preparations.

G-actin forms different polymers when incubation with Gd III ions is followed by the addition of 0.1 M KCl. Figure 2*a* summarises our previously reported data on the changes in viscosity in these conditions[7,8]. Figure 2*b* shows an example of the polymers formed in the presence of KCl at a molar ratio of 6 mols or more of Gd III per mol actin. The length of the polymers is variable from ~0.3 to ~1.5 μm but each polymer has a uniform width of about 200 nm ± 10 nm. In each polymer two sets of diagonal striations spaced about 5.5 nm apart can be seen intersecting one another at equal and opposite angles of approximately 80° with respect to the sides of the structure. This is seen more clearly when the micrograph is viewed at an oblique angle. Occasionally at the ends of the polymer only one set of striations is observed and here the 5.5-nm repeat is distinctly seen. These observations suggest that the main part of the polymer is a flattened tube with the two sets of striations coming from strands that form the front and back of the polymer. We therefore propose to call these structures actin tubes. As in the microcrystals, no 36-nm repeat and no F-actin filaments can be seen in these preparations. Rope-like aggregates which have a similar appearance to the extra material seen with microcrystals are sometimes seen associated with actin tubes. This extra material may be associated with the formation of both structures.

Fig. 2 *a*, Effect of Gd III on the reduced viscosity of actin in the presence of KCl. Reaction conditions are the same as described in Fig. 1*a* except that following a 5 min incubation of G-actin with Gd III, KCl was added to give a final concentration of 0.1 M. *b*, An actin tube formed with Gd III in conditions specified by the black dot in 2*a*. The arrow indicates an end of a tube where only one side of the structure can be seen. Negatively stained with 1% uranyl acetate. ×134,000.



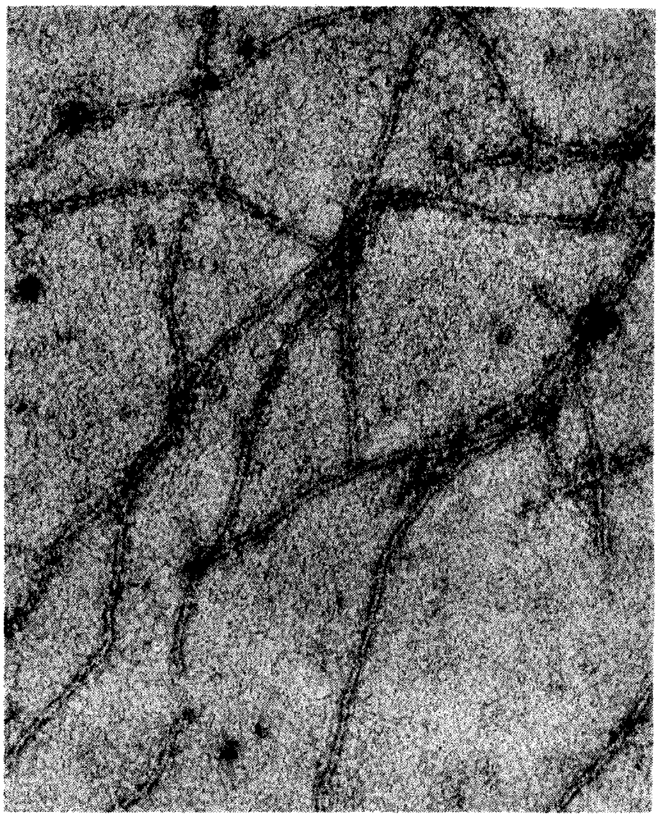


Fig. 3 Network of F-actin formed at the peak of the reduced viscosity in the conditions indicated by the arrow in Fig. 2*a*. No actin tubes were observed in these conditions stained with 1% uranyl acetate. ×126,000.

We have shown (Fig. 2) that in the presence of 0.1 M KCl actin tubes are formed with 6 mols or more of Gd III per mol G-actin. No F-actin is formed as judged either by viscometry or by electron microscopy. However, with less than 5.5 mols Gd III per mol G-actin, addition of 0.1 M KCl causes a large increase in the observed viscosity, suggesting that polymerisation into F-actin had occurred. Samples examined at the peak of the viscosity in the electron microscope (Fig. 3) show that the actin has polymerised into F-actin filaments which have aggregated into a loose meshwork. In a few places we can observe a side-by-side arrangement of the filaments. F-actin were observed over the range 0–5.5 mols Gd III per mol actin. Thus the lanthanide ions do not inhibit the formation of F-actin until a certain critical molar ratio is reached.

The actin used in this study migrated as a single band on SDS gel electrophoresis. The formation of actin microcrystals and actin tubes is completely reversible when the Gd III concentration is lowered. There is therefore little doubt that these structures are composed entirely of actin and that their formation is due to the presence of the lanthanide ions. Furthermore, G-actin after incubation with Gd III followed by removal of the lanthanide will polymerise into F-actin[8]. It is evident that the actin has not been denatured by the lanthanide ions. The absence of F-actin formation together with the observation that neither the microcrystals nor the actin tubes possess the 36-nm axial repeat characteristic of the long helical pitch of F-actin shows that these structures are not composed of F-actin and represent some previously undescribed form. Further structural studies are in progress (M. J. D. and C. G. dos R., in preparation). These modes of actin assembly should provide new insights into the size, shape and molecular interactions of actin subunits.

Asymmetry in the primary structure of undegraded phytochrome

PHYTOCHROME is the photoreceptor for many light-mediated developmental responses in plants[1]. This chromoprotein, considered a dimer of apparently identical 120,000-dalton subunits (undegraded phytochrome)[2,3], has often been purified from oats as a monomeric 60,000-dalton degradation product (degraded phytochrome)[2,3] because of its susceptibility to proteases present in crude extracts[3]. Degraded phytochrome is relatively resistant to further proteolysis and has almost the same photochemical properties as undegraded phytochrome[2]. Immunochemical evidence[4] indicates that undegraded phytochrome is asymmetric, possessing extensive primary structure not found in degraded phytochrome. In contrast, recent peptide-map data, obtained by a fluorescence procedure, have led to the conclusion that undegraded phytochrome is symmetric, being composed of two nearly identical halves, each half being equivalent to the 60,000-dalton, photoreversible degradation product[5]. We present here autoradiographic tryptic digest maps of iodinated degraded and undegraded phytochrome from etiolated oat (*Avena sativa* L., cv. Garry) seedlings that offer additional evidence concerning asymmetry in the primary structure of undegraded phytochrome.

Two tryptic digest maps of degraded and five maps of undegraded phytochrome were prepared from the same number of different preparations using phytochrome bands cut from SDS–polyacrylamide gels (Fig. 1). The map of degraded phytochrome (Fig. 2*a*) contains all but one of the spots (unlabelled arrow) found on the map of undegraded phytochrome (Fig. 2*b*), which contains nine additional spots of comparable intensity (unlabelled arrows). Replicate maps (not shown) gave the same patterns as in Fig. 2. Unmarked spots seen on one map but not the other are revealed by longer exposures of the same maps and therefore are not unique. The existence of a unique spot on the degraded phytochrome map is reasonable as the endoproteases that produce degraded phytochrome may not have the same specificity as trypsin. At least one terminus of the degraded chromopeptide would then have been cleaved between residues that are recognised by trypsin. The peptide subsequently derived by trypsin degradation would have only part of the primary structure found in the analogous peptide in phytochrome that had not been degraded by endogenous proteases. This peptide could also account for one of the additional spots on the undegraded phytochrome map. The remaining eight additional spots represent peptides not found in degraded phytochrome. Even if our interpretation of which spots are homologous (lettered arrows) is in error, the number of spots on the undegraded phytochrome map that cannot be accounted for on the degraded phytochrome map would still be a minimum of eight. As the number of spots on the map of undegraded phytochrome is almost twice that on the degraded phytochrome map, undegraded phytochrome is apparently composed of only one copy of the degraded molecule and an approximately equal amount of unrelated primary structure.

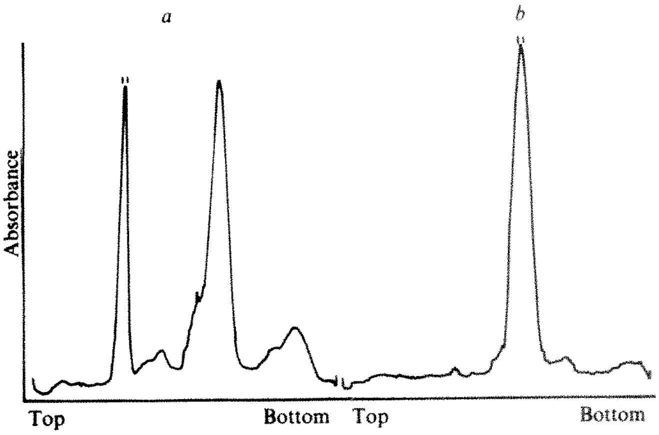

Fig. 1 Absorbance scans of 5 mm diameter, cylindrical SDS–polyacrylamide gels of *a*, an immunoprecipitate of $\sim 10\ \mu g$ of undegraded phytochrome, with the 120,000-dalton phytochrome subunit (left) and the 50,000-dalton heavy and 25,000-dalton light chains of immunoglobulin G, and *b*, $\sim 10\ \mu g$ of purified 60,000-dalton degraded phytochrome. The portion of each phytochrome band (central 1 mm) cut out for analysis is indicated by the hash marks. Undegraded phytochrome was partially purified from dark-grown oat seedlings through the first ammonium sulphate fractionation as described previously[6], and then precipitated with specific antiphytochrome serum. Degraded phytochrome was purified from the same oat cultivar using the method described by Rice *et al.*[7], except that all buffers before the Bio-Gel P-150 column contained 14 mM 2-mercaptoethanol, and a linear salt gradient elution from brushite was performed before Bio-Gel P-150 chromatography. Both phytochrome preparations were denatured by heating in 1% (w/v) SDS and 0.79 M 2-mercaptoethanol, were electrophoresed through 5% (w/v) polyacrylamide gels with 0.14% (w/v) *N-N'*-methylenebisacrylamide for 5h at 8 mA per gel, as described by Weber and Osborn[8], and were stained for protein using Coomassie blue. Mobilities of proteins were compared to standards for size determination (see Fig. 3 in ref. 2).

It has been argued that 40–50 peptides represents the upper limit of resolution of a two-dimensional peptide map[10]. As tryptic digestion of even degraded phytochrome yields at least 55–60 peptides[5], the selectivity of the method used here in

0028–0836/78/0276—0733$01.00

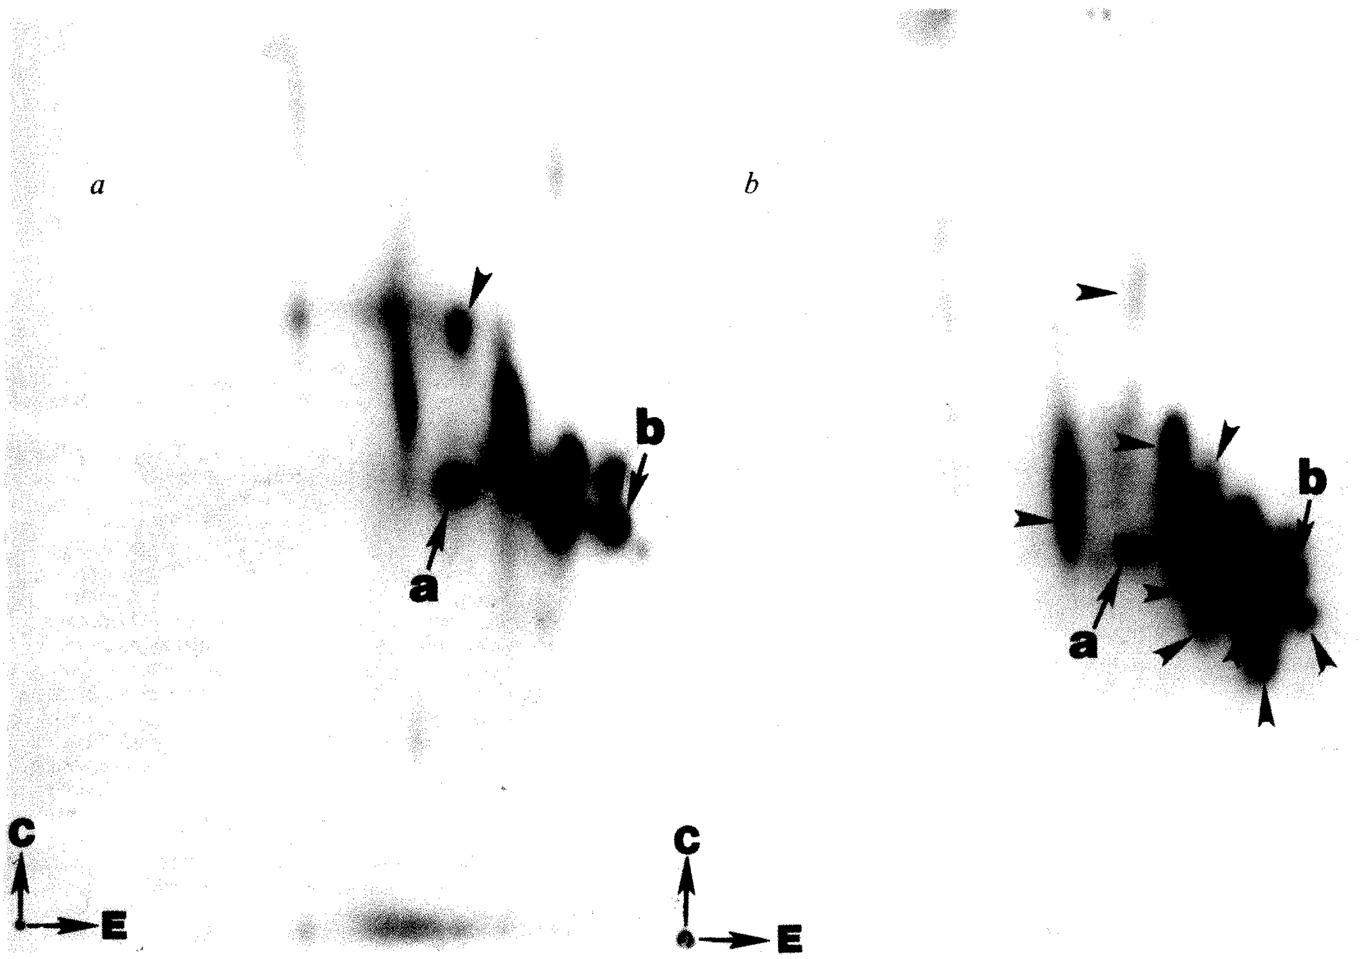

Fig. 2 Autoradiographs of tryptic digest maps of *a*, degraded and *b*, undegraded phytochrome prepared in a single experiment. Lettered arrows indicate corresponding spots; unlettered arrows unique spots. Two dimensional tryptic fingerprinting of ^{125}I-labelled polypeptides was performed essentially as described by Elder *et al.*[9] Each 1-mm thick gel slice (see Fig. 1) was placed in a siliconised test tube, washed extensively with 25% (v/v) isopropanol and then with 10% (v/v) methanol and dried by vacuum desiccation. The following components were added sequentially to each dried gel slice: 20 μl 0.5 M sodium phosphate buffer (*p*H 7.5), 300 μCi sodium ^{125}I (NEN, carrier free, 17 Ci mg^{-1}) and 5 μl 1 mg ml^{-1} chloramine T (Sigma). The gel slices were allowed to absorb the liquid for 30–45 min, and then 1 ml of 1 mg ml^{-1} sodium bisulphite was added to terminate the reactions. After 15 min the bisulphite solution was removed. The slices were placed into individual nylon pouches and allowed to dialyse at least 24 h against 4 one-litre changes of 10% (v/v) methanol. Following dialysis each gel slice was removed from its pouch with a spatula, placed in a siliconised tube and dried by vacuum desiccation. To each tube 1 ml of 50 μg ml^{-1} TPCK-trypsin (Worthington) in 50 mM ammonium bicarbonate was added. The gel slices were incubated for 24 h at 37 °C after which each supernatant was removed and lyophilised. Each trypsin-digested sample was dissolved in 20 μl of acetic acid, formic acid and water (15 : 5 : 80), and then 5–10 μl of the samples were spotted on 20 × 20 cm cellulose-coated thin layer plates (Eastman, 13255 cellulose, without fluorescent indicator) for electrophoresis. Electrophoresis was carried out for 1 h at 1 kV in a Savant flat bed electrophoresis apparatus maintained at 2–4 °C. After electrophoresis the plates were dried and the peptides chromatographed in a second dimension using butanol, pyridine, acetic acid and water (32.5 : 25 : 5 : 20). Following chromatography the plates were dried and wrapped in cellophane. Plates were placed over X-Omat R X-ray film (Eastman) so that peptides could be located by autoradiography. Both plates were photographed on a single roll of Kodak Panatomic X film and were printed on paper of identical contrast. Directions of electrophoresis (E) and chromatography (C) are indicated at the origin. Longer exposures of the maps (not shown) indicate that spots on a map that are unmarked (for example, Fig. 2*a*, intense spot immediately to the left of unmarked arrow and numerous faint spots around main pattern) are also found on the alternate map and therefore are not unique.

visualising primarily only tyrosine-containing peptides, though a potential drawback, is advantageous for our purposes. Residues other than tyrosine are also labelled by this method, but at a lower rate. In addition, the rate of deiodination of these other residues is rapid enough to make it very unlikely that any major spot is due to iodination of a residue other than tyrosine[11]. As the samples were handled identically, any potential labelling of other amino acids would be identical for both maps.

Amino acid analyses indicate that degraded phytochrome contains 10–18 tyrosyl residues and undegraded about 26 residues[2,5]. These are sufficient tyrosines to permit critical comparison of the two maps, but few enough to minimise apparent coincidence of similarly migrating, but non-homologous, peptides. The number of spots on the undegraded phytochrome map is smaller than the expected maximum of 26, probably because some peptides contain multiple tyrosines. The possibility that a peptide is seen in only one map because of the absence of a labelled tyrosine in one case but not the other is precluded because both maps are derived from the same gene products and because these products are labelled after denaturation. Labelling of each sample seems to be complete as the map of degraded phytochrome is completely contained in the map of undegraded phytochrome with the exception of the spot referred to above. Peptides arising from the self-digestion of trypsin[12] are not visualised on the autoradiographs of our maps because trypsin is not added until after residual ^{125}I and chloramine T are removed. Coincidence of a serum protein with the 120,000-dalton phytochrome band is also not a problem as crude serum has no band at this position. Maps prepared from gel slices lacking protein gave totally blank autoradiographs.

The conclusion derived from immunochemical evidence[4] is the same as that derived from the peptide maps reported here.

Limited proteolysis of undegraded phytochrome yields at least two distinct peptides recognised by antiserum against undegraded but not degraded phytochrome. One of these peptides is ~90,000 daltons as estimated by gel exclusion chromatography. This size, which is probably an overestimate due to non-globular shape, indicates that the peptide, which does not contain a detectable chromophore, represents about one-half of the 120,000-dalton monomer of undegraded phytochrome. As each of the large variety of immunoglobulin Gs in the antiserum against degraded phytochrome recognises a different section of primary structure[13], it is very unlikely that this '90,000-dalton' peptide has any appreciable primary structure in common with degraded phytochrome.

The data presented here, together with the immunochemical data published earlier[4], support the same conclusion: that the 120,000-dalton, undegraded phytochrome subunit contains a single copy of the 60,000-dalton, degraded phytochrome monomer and approximately 60,000 daltons of unrelated primary structure. This conclusion conflicts with the earlier interpretation by Stoker *et al.*[5] of peptide maps (photographs of which were not presented) that visualised all products of tryptic digestion, rather than the limited number examined here.

C-terminal side of α-helix is more stable than N-terminal side

THE stability of the polypeptide chain of the α-helix has been extensively studied by both experimental and theoretical examination of the transition from the α-helical to random coil conformation of different homopolypeptides[1,2]. In these studies, the α-helix has been treated symmetrically along the helical axis. Amino acid residues located at the *n*th position from the N terminus and the C terminus of the α-helix in a homopolypeptide are assumed to behave in the same manner. However, the stability of the α-helix in the N-terminal region must be different from that in the C-terminal region, due to some extent to the asymmetrical nature of the peptide bond. It has not previously been known whether or not the influence of a polypeptide in random conformation is independent of the side of the α-helix to which the polypeptide is attached. We report here the first experimental evidence for such asymmetrical behaviour.

To detect asymmetry in the α-helix, we prepared block co-polypeptides such that their amino acid compositions were the same but their sequences were reversed with respect to each other; asymmetrical differences in a homopolypeptide are not distinguishable. As previously described[3], we synthesised two kinds of block co-polypeptides, $(\text{L-Glu})_{20}(\text{L-Ala})_{20}\text{Phe}$ (designated EAF) and $(\text{L-Ala})_{20}(\text{L-Glu})_{20}\text{Phe}$ (designated AEF) by a fragment-peptide-coupling technique on a solid support using $(\text{BOC-L-Glu})_4$ and $(\text{BOC-L-Ala})_2$. We determined the difference between the α-helical content of each block co-polypeptide in aqueous solution at the same *p*H, temperature and salt concentration as described below.

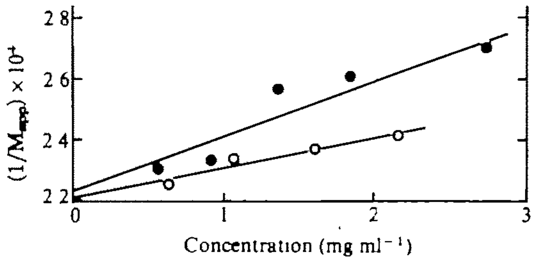

Fig. 1 Results of sedimentation equilibrium experiments for EAF (●) and AEF (○). The experiments were carried out with a Spinco model E analytical ultracentrifuge using the interference optics at 25 °C at 29,500 r.p.m. for 24 h. The block co-polypeptides were dissolved in 0.1 M KF, 20 mM Na-phosphate buffer, *p*H 8.0 (KF was selected as a neutral salt with a low extinction to 190 nm to measure CD spectra). A partial specific volume of block polypeptides, $\bar{v}$, was taken as 0.63, which is the average weight of partial specific volumes of potassium glutamate (0 57) (refs 12, 13) and alanine (0.74) (ref. 14). The molecular weights (MW) of both polypeptides extrapolated to infinite dilution by the least-squares method were 4,500 M_{app}, apparent molecular weight.

Care was taken to obtain uniform block co-polypeptides. The polypeptides, fractionated by repeated gel filtration on Sephadex G-50, had amino acid compositions of Ala = 21.4, Glu = 21.7, against Phe at the C-terminal end (used as the internal standard) for EAF, and Ala = 19.9, Glu = 20.8 for AEF, in agreement with the calculated values. The presence of any aggregations or micelles could result in artificial differences in the α-helical contents of both block co-polypeptides; micelle formation might occur rather easily for polypeptides containing polyalanine. The materials were monodisperse in solution, as rechromatography on Sephadex G-50 gave only a single peak. This observation was supported by the sedimentation equilibrium experiments shown in Fig. 1. Both polypeptides had the same molecular weight of 4,500, in good agreement with the calculated values from the amino acid compositions. The finding that the slopes against concentration (that is, the second virial coefficients) are different—greater for EAF than for AEF—suggested that the conformations differ from each other in solution. As micelle formation seemed likely to be the most serious problem in this experiment, the circular dichroic (CD) measurements were carried out at various concentrations in the range 0.003–3 mg ml⁻¹. No concentration effect was observed and so further measurements were made at a concentration of 0.1 mg ml⁻¹.

0028-0836/78/0276—0735$01 00

Figure 2 shows the CD spectra of EAF at *p*H 5.22, 5.56, and 8.53 at 25 °C. The typical CD curve of the α-helix at *p*H 5.22 has two minima, at 223 nm and 208 nm, and one maximum, at 191 nm; it changes with the increase in *p*H, indicating that the ionisation of carboxyl groups in L-Glu residues causes the collapse of the α-helix into the random coil conformation. The presence of the isodichroic point at 204 nm implies that the transition occurs between two states, α-helix and random coil. The α-helical spectrum represented by the minimum at 223 nm still occurs at *p*H 8.53; this may be attributed to the polyalanyl block in the material, for there is no ionisable group in the alanine side chain, whereas the polyglutamyl block takes a random coil conformation at this *p*H. We examined whether or not the CD spectra of AEF are coincident with those of EAF.

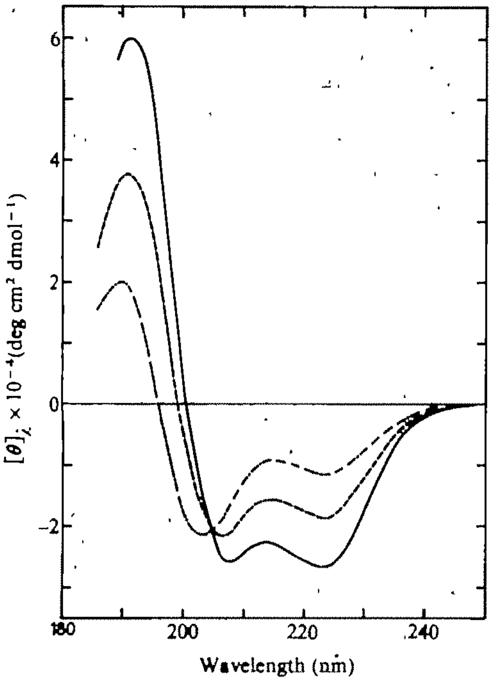

Fig. 2 Circular dichroic spectra for EAF at 25 °C. Solid line, *p*H 5.22; dashed line, *p*H 5 56; dashed-dotted line, *p*H 8.53. CD measurements were carried out with a JASCO J-20 spectropolarimeter using a cell of 1 mm path length. The *p*H of solutions (in 0.1 M KF) was adjusted by the addition of a small amount of KOH or $HClO_4$ to the desired values. Concentrations of polypeptides were 0.1 mg ml^{-1}.

Plots of ellipticities at 223 nm, $[\theta]_{223}$ (a measure of α-helical content), for EAF and AEF are shown in Fig. 3 as a function of *p*H. Apparently, $[\theta]_{223}$ increases with increase in *p*H and the transition *p*H of EAF is higher (*p*H 5.4) than that of AEF (below *p*H 5.0). The values of $[\theta]_{223}$ become constant above *p*H 6.5, but are always lower for AEF than for EAF. These results indicate that EAF has a higher α-helical content (32% calculated on the basis that $[\theta]_{223} = -37{,}000$ deg cm^2 dmol^{-1} for the full α-helix, and 900 for the random coil[4–6]) than AEF (16%) in the same conditions. As the block co-polypeptides are monodisperse in solution (Fig. 1), the stability of the α-helix of the polyalanyl portion must be affected differently by the conformation of the polyglutamyl block and depends on which side the block is connected, the polyalanine helix being more unstable when the charged polyglutamyl block is attached to the C terminus of the helix. Experiments on thermal denaturation of the same materials were consistent with these results, and will be reported in detail elsewhere.

The difference might originate from the Phe residue added to the C terminus as the internal standard, through hydrophobic stabilisation of the α-helix. However, a single additional residue is not sufficient to account for the observed difference of 16% in the helical content. If this were the reason, one extra residue at the C terminus should exert a stabilising effect over 6 to 7 residues in the α-helix. Another possible cause for the asymmetry might be some contribution from the electrostatic interaction of the negative charges on Glu residues with the helix dipole or with peptide dipoles. As the electrostatic interaction in aqueous solution may be weakened by the addition of salts, we examined the effect of salts on the results. The difference observed even at 0.5 M concentration of salts show that the electrostatic effects are not enough to explain the asymmetry, although further detailed examination is required. Therefore, we may conclude that the difference is based on an intrinsic property of the α-helix.

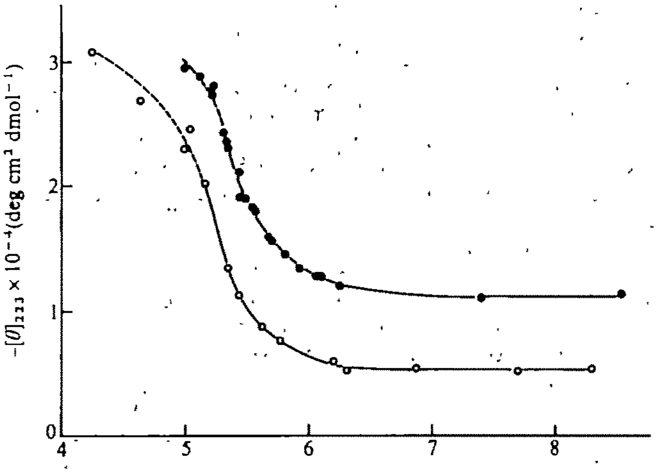

Fig. 3 Ellipticities at 223 nm, $[\theta]_{223}$, plotted against *p*H for EAF (●) and AEF (○) at 25 °C in 0.1 M KF. The dashed lines represent the region where precipitates appeared. The solutions in this region became turbid with standing, so that accurate measurements were impossible below *p*H 5.0.

The presence of the asymmetry reported in this study was suggested by simple theoretical calculations on the α-helical conformation[7,8]. Also, conformational analyses on three-dimensional structures of proteins demonstrate the presence of asymmetrical structures in proteins[9–11]; these, however, could be ascribed to heterogeneous alignment of amino acid residues in a protein. A theoretical basis to account quantitatively for this asymmetry of the α-helix remains to be developed.

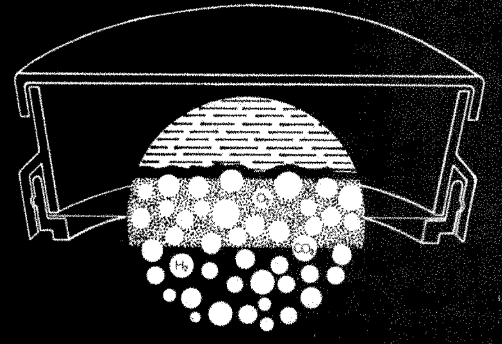
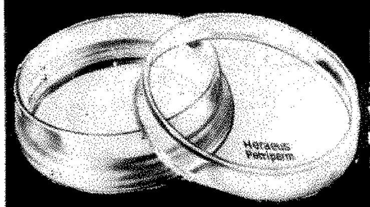
A new approach in tissue culture



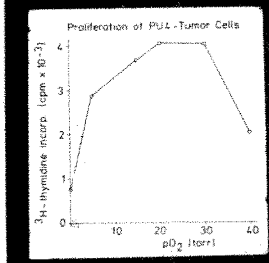


PETRIPERM
a novel culture dish with gas permeable membrane as cellular support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents

PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.



In the intact animal, the pH and the partial pressure of both oxygen and CO_2 of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO_2, pCO_2 and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 μm thick membrane.

Heraeus—
Co_2-Incubator

Palaeogeotherms: implications of disequilibrium in garnet lherzolite xenoliths

FRASER AND LAWLESS[1] have pointed out that, because of the different diffusion mechanisms involved, the two-pyroxene geothermometer[2,3] and the garnet–orthopyroxene geobarometer[4,5] commonly used[6–8] in the interpretation of the pressure–temperature equilibration conditions and depths of derivation of garnet lherzolite xenoliths in kimberlites may be out of phase and thus generate a spurious apparent geotherm. Whilst this may be the case it should, however, be noted that the lines of constant K for garnet–orthopyroxene equilibria in Fig. 1 of Fraser and Lawless[1] are, in the depth range of interest, effectively sub-parallel to geotherms independently calculated[9] from heat flow–production studies. This essentially makes it impossible to determine whether geotherms calculated from xenolith data are real or spurious in the way suggested.

Their Fig. 1 thus highlights the critical importance of the temperature estimates to the depths of origin inferred for such xenoliths. Their further discussion, therefore, purporting to demonstrate the different diffusion blocking temperatures for element exchange reactions between various mineral pairs in garnet lherzolite xenoliths is crucial but quite unconvincing and rather misleading.

Fraser and Lawless attempted to test the possibility that diffusion between pyroxenes and garnets is less rapid than between coexisting pyroxenes by comparing the distribution coefficients for Mg–Fe^{2+} exchange between garnet–clinopyroxene and garnet–orthopyroxene pairs with temperatures based on the Ca–Mg exchange between coexisting pyroxenes[3]. They interpreted the arrays of data points in their Fig. 2 as indicating that Mg–Fe^{2+} exchange between pyroxenes and garnet is effectively blocked below ~1,100 °C whilst lower temperatures continue to be monitored by Ca–Mg exchange between coexisting pyroxenes. In reaching this conclusion they ignored the fact that the xenoliths concerned have probably been derived from an appreciable depth zone in the mantle and hence may be expected to have equilibrated over a range of pressures as well as temperatures. Furthermore, clearly both Mg–Fe^{2+} exchange between pyroxenes and garnets and Ca–Mg exchange between coexisting pyroxenes depend on pressure as well as temperature, although there are uncertainties as to the magnitudes of the pressure dependence of these exchange reactions[2,10–13]. Certainly it is unreasonable for Fraser and Lawless to expect that the xenoliths would plot along lines defining the temperature dependence of the Mg–Fe^{2+} distribution coefficients at effectively one particular pressure. Indeed the experimental evidence of Råheim and Green[12] that $(\mathrm{Mg/Fe^{2+}})_{\mathrm{cpx}}/(\mathrm{Mg/Fe^{2+}})_{\mathrm{gnt}}$ decreases with temperature but increases with pressure suggests that the arrays of points on Fig. 2 of Fraser and Lawless may simply reflect the combined pressure/temperature effects on the distribution coefficients involved.

The variation in $(\mathrm{Mg/Fe^{2+}})_{\mathrm{cpx}}/(\mathrm{Mg/Fe^{2+}})_{\mathrm{gnt}}$ between garnet–clinopyroxene pairs in different metamorphic environments[14,15,19] indicates that Mg–Fe^{2+} exchange is normally effective at temperatures well below 1,100 °C. Krogh[16], Råheim and Green[17], for example, have described both prograde and retrograde variations in this distribution coefficient in eclogite assemblages which indicate that above ~700 °C, diffusion rates even in garnets are fast enough to chemically homogenise the minerals. At lower temperatures Mg–Fe^{2+} exchange is not completely blocked but is restricted to the extent that pronounced zoning is produced and retained, especially in the garnets[16].

Thus contrary to the impression given by Fraser and Lawless and to the interpretation which they place on their Fig. 2, petrographic[16–19] and experimental[2,10–12] evidence indicate that Mg–Fe^{2+} exchange reactions between pyroxenes and garnets probably provide far more sensitive geothermometers below 1,100 °C than the Ca–Mg exchange between coexisting pyroxenes. However, the magnitude of the pressure effect on the Mg–Fe^{2+} exchange reactions in garnet lherzolite assemblages and reliable estimates of the Fe^{2+}/Fe^{3+} ratios in these minerals[19] must first be determined before one can hope to obtain geologically meaningful temperatures from even these geothermometers and hence calculate valid geotherms.

I thank Dr W. L. Griffin for his helpful comments.

FRASER AND LAWLESS reply—We completely agree[1] with Carswell that the similarity between the temperature dependence of the garnet–orthopyroxene geobarometer[2] and likely geothermal gradients makes it difficult to use this reaction to distinguish between the effects of differences in blocking temperatures and temperature–pressure distributions obtained from samples which have equilibrated at different depths along such geothermal gradients.

In the absence of a suitable alternative geobarometer with a different slope it is difficult to distinguish between these two possibilities or indeed some combination of both. It is, however, unsound to make Carswell's *a priori* assumption that the xenoliths in question are derived from different depths and to use such an assumption to require that the nodules show an appreciable effect of pressure on Fe^{2+}–Mg distribution coefficients. This may indeed be the case as may bulk-compositional effects such as we have mentioned[1]. However, the observed departure of garnet–pyroxene Fe^{2+}–Mg distribution coefficients from the equilibrium values at 30 kbar is equally consistent with increased departure from equilibrium at lower temperature. The extent of low temperature Fe^{2+}–Mg exchange observed in the eclogitic assemblages of Krogh[3] and Råheim and Green[4] results from equilibration over long periods of geological time and cannot be directly compared with the proposed retrograde effects on garnet lherzolite nodules resulting from relatively rapidly changing temperature–pressure conditions during movement towards the Earth's surface before final eruption of the kimberlite.

These important questions can only be resolved by independent tests. The calibration of an alternative geobarometer with different slope is clearly important. Moreover, the bulk chemical homogeneity of the phases in the xenoliths

0028–0836/78/0276—0737$01 00

should be critically analysed in terms of likely diffusion models and tests should be made of the homogeneity and equilibration of isotopes and refractory trace elements among different mineral phases. Recently published data[5] show a correlation of pyroxene–garnet Mn/Mg and V/Al ratios with clinopyroxene–orthopyroxene temperatures suggesting equilibration of these trace elements. However, the same authors note grain-by-grain relative inhomogeneities of 25% in Cr and Sc contents of the garnets and similar results have been observed elsewhere[6]. Similarly our work has shown that pyroxene–garnet Cr/Al distribution coefficients are widely scattered for the low temperature group of granular nodules but are more tightly grouped in the case of sheared nodules. Isotopic disequilibrium in garnet and spinel lherzolite nodules has also been reported[7–10] although it seems that in the case of garnet lherzolites this applies only to sheared nodules, the granular nodules being apparently equilibrated and giving ages close to that of the host kimberlite[7], despite their dominantly lower temperatures.

There are thus several contradictory pieces of evidence concerning equilibrium in garnet lherzolite and xenoliths and hence uncertainty in their use for the calculation of geothermal gradients. When alternative geobarometers and more isotopic, trace element and kinetic data become available these issues should be more easily resolved.

Paternal behaviour in fishes: a question of investment, timing or rate?

DAWKINS AND CARLISLE[1] have shown that Trivers' parental investment model[2] of tetrapod maternal care rests on a fallacy, and suggest that maternal behaviour in tetrapods and paternal behaviour in teleost fishes is a result of the relative timing of gamete release. Like Dawkins[3], I view evolution as the selective transfer of information from generation to generation. However, I believe the fundamental difference between the sexes that leads to exclusive maternal or paternal care is the relative rate at which the two sexes can create gametic copies (spermatogenesis requires less time than oögenesis).

In externally fertilising species, optimal sites for zygote development may constitute a limiting resource for spawning individuals, which selects for site constancy and territorial behaviour. Males are favoured as site-constant individuals because in fishes (as in most vertebrates) males are able to produce new batches of fertile gametes and remate at shorter intervals than females[4–8]. A male monopolising a site will leave more descendants than a female occupying that site for the same duration. The male can remate, so roving females still spawn at their maximum rate, and their sons will show the site-constant trait. A territorial male's success is limited by the number of females he can attract; hence the sexual adornment in parental male fishes[9–11]. Parental behaviour evolves as a consequence of acts by the male that promote survival of the zygotes at his site. Where reproduction is not tied to a site, the female will be favoured as the parent because her potential gain from multiple mating is the lesser.

The relative rate of production of gametes is central to the question of sexual selection and follows directly from Dawkins' property of 'fecundity'[3]. Questions of efficiency and energy are not important, except in that they influence the rate of reproduction. The model can be used to explain the evolution of anisogamy, substituting rate for the numerical productivity used by Parker, Baker and Smith[12]. The present model views the evolution of solitary male or female parental care as a cooperative outcome that allows individuals of each sex to maximise their production of offspring.

I thank Jack P. Hailman, Leigh Hurst and Scott Robinson for helpful discussions.

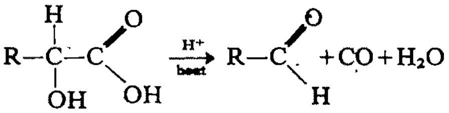
Acid hydrolysis and α-hydroxy acids in meteorites

THE study by Peltzer and Bada[1] of α-hydroxycarboxylic acids in the Murchison meteorite is of considerable interest because if not only presents a different class of molecules to be looked for in meteorite studies, but also provides a possible method for an evaluation of the ammonia content of the environment in which the synthesis of the organic compounds took place. However, I feel that their analyses of the results leave a room to be filled.

They found less α-hydroxy acids in the acid-hydrolysed water extract fraction than in the unhydrolysed fraction. It is known that α-hydroxy acids decompose to aldehyde and CO when boiled in dilute sulphuric acid, with an overall reaction



$$R{-}CH(OH){-}COOH \xrightarrow[\text{heat}]{H^+} R{-}CHO + CO + H_2O$$

As this reaction is known to proceed quite readily, I suspect that this could be the main cause of their observation. Peltzer agreed on this point in his personal communication, saying "the acid-catalysed decomposition of α-hydroxy carboxylic acids probably accounts for the decreased recoveries of the compounds following acid hydrolysis". This in turn would question their conclusion that the hydroxy acids in the meteorite exist primarily in a free or water-hydrolysable state, as their procedure allows whatever α-hydroxy acids are produced through the acid hydrolysis to decompose at the same time to aldehydes. Their conclusion still seems valid, however: Peltzer, in the same personal communication, states that the recoveries of standard compounds at levels equivalent to those found in the meteorite were measured, and that acid hydrolysis recoveries for most hydroxy acids were approximately 10–20% lower than those by water hydrolysis; this extent of the decomposition does not seem large enough to reverse their conclusion.

As the majority of amino acids in meteorites exists in some kind of precursor form and is released only on hydrolysis in 6 M HCl (ref. 2), it would certainly be interesting to study the possible causes for the different states of existence of α-hydroxy acids and of amino acids.

JEEM

Journal of Embryology and Experimental Morphology

Edited by: R. M. Gaze, London; R. J. Cole, Sussex; R. L. Gardner, Oxford and P. A. Lawrence, Cambridge.

The Journal is owned by the Company of Biologists Ltd.* and is published for the Company by Cambridge University Press. The Company of Biologists and Editors of the Journal would like to make the following statement to all Developmental Biologists:

The Journal exists to publish work which gives insight into the mechanisms of development at all levels of organisation including molecular, cellular and tissue. It thus welcomes studies dealing with differentiation, pattern formation, morphogenesis, growth, regeneration and ageing. Papers will be primarily considered in terms of the contribution they make to the understanding of developmental mechanisms.

1. With effect from January 1979, a new and enlarged Editorial Advisory Board is being appointed to facilitate the reviewing of papers. The membership of the Board will reflect the aims of the Journal as stated above. Within the general field of Developmental Biology the Editors would like particularly to invite studies on Developmental Genetics, Developmental Neurobiology and Biochemical studies where the role of molecular mechanisms in developmental changes is emphasised.

2. The design of the Journal cover is being altered.

3. The Journal will henceforth accept papers in English only. Previously a small number of papers was published in other major European languages. The present change is designed to increase the accessibility of the contents of the Journal to the world-wide scientific community. Authors whose own language is other than English may, if they so wish, provide a translation of the Summary of their paper into their own language.

4. The Journal has no page charges.

5. Each paper accepted entitles the authors to 200 free reprints.

6. The Journal is published in hard covers, thus relieving individual recipients and libraries of binding costs.

7. The Journal is published on high quality art paper, thus permitting the best reproduction of half-tone illustrations. The high quality of illustrations of the Journal is being further improved by printing modifications.

8. Publication time in the Journal is at present competitive with other major Journals. Continuing efforts will be made to shorten this still further.

9. Authors are granted permission, without the need to notify the Company, to reproduce their papers, provided that such copies are for free distribution and will not be sold.

*The Company of Biologists Ltd. is an independent organisation (registered as a charity) whose members are active professional biologists. The Company, which was founded in 1925, and owns *Journal of Experimental Biology* and *Journal of Cell Science*, as well as *Journal of Embryology and Experimental Morphology*, exists to disseminate knowledge of biology.

Circle No. 13 on Reader Enquiry Card.

Theory and Practice in Affinity Techniques

edited by P. V. Sundaram and F. Eckstein

December 1978/January 1979, approx. 250pp., £10.50/$21.75 0.12.677150.0

The book is based on an International Symposium, 'Theory and Practice in Affinity Techniques', held at the Max-Planck Institut für Experimentelle Medizin, Göttingen, in April 1978. The contributors have included information both from their lectures and from the discussions held at the Symposium, while an Editor's Note at the end gives a summary of the discussions on controversial issues in affinity chromatography. The book is a much needed addition to the literature on affinity chromatography and affinity labeling, providing all those concerned with these techniques the chance to learn of the most up-to-date developments from leading workers in the field.

The Society for Applied Bacteriology Technical series No. 11

Techniques for the Study of Mixed Populations

edited by D. W. Lovelock and R. Davies

December 1978/January 1979, xii+228pp., £12.50/$25.75 0.12.45650.2

There has been a considerable increase in interest over the last few years in the interactions between various micro-organisms in particular environments and ecological niches, and also between micro- and macro-organisms. These studies present very different problems from the study of micro-organisms in isolation in pure culture, so that the existing techniques are not entirely appropriate. This book therefore makes a timely contribution to this area, bringing together many methods and techniques which have been developed to study mixed cultures occurring naturally in divers habitats.

Advances in Botanical Research Volume 6

edited by H. W. Woolhouse

January/February 1979, approx. 380pp., £16.00/$33.25 0.12.005906.1

The aim of this series is to present authoritative statements in specialized fields of botanical enquiry which are currently in the process of rapid development, or where the need for a review is indicated by renewed interest in a well-established area.

Contents

J. A. Lee and G. R. Stewart: Ecological aspects of nitrogen assimilation. *U. Zimmermann and E. Steudle:* Physical aspects of water relations of plant cells. *Keith Jones:* Aspects of Chromosome evolution in higher plants. *A. J. E. Smith:* Cytogenetics, biosynthesis and evolution in the Bryophyta. *B. Dell and A. J. McComb:* Plant resins — their formation, secretion and possible functions.

Proceedings of the Serono Foundation Symposia No. 22

Clinical Psychoneuroendocrinology in Reproduction

edited by L. Carenza, P. Pancheri and L. Zichella

January/February 1979, xiv+470pp., £16.80/$34.75 0.12.159450.5

Psychoneuroendocrinology is an attempt to provide the essential interdisciplinary approach to research in human reproduction. It involves psychiatrists and psychologists to examine the intrapsychic and psychological determinants of emotions, neuroendocrinologists to relate animal research to clinical studies in man, and obstretricians and gyneocologists to apply these data in the fields of physiology and pathology of reproduction. This book is based on a symposium which brought together people from all these disciplines, to discuss their various approaches to the subject and it clearly demonstrates the need for continued coordination of the different groups involved in psychosomatic research.

Biochemical and Biophysical Perspectives in Marine Biology Volume 4

edited by D. C. Malins and J. R. Sargent

December 1978/January 1979, xii+240pp., £17.00/$35.25 0.12.466604.3

Heavy ion reactions

Ricardo A. Broglia

Nuclear Heavy Ion Reactions. By P E Hodgson. Pp.588. (Oxford University Press, Clarendon. Oxford, 1978) £18

OUR present understanding of the nuclear structure is, to a large extent, based on the information obtained from the analysis of reactions induced by protons, neutrons and light ions, in which the nucleus is moderately excited.

A central feature of the nuclear many-body problem is that the field which confines protons and neutrons is created by the nucleons themselves. This self-confinement is such that the nucleus displays both the degrees of freedom associated with the motion of individual nucleons, as well as collective degrees of freedom where the nucleus reacts as a whole to the external probe. The description of the interplay between the collective and single-particle elementary modes of nuclear excitation constitutes one of the most challenging and exciting problems in the field of many-body physics.

Developments of heavy ion accelerators in recent years have opened the possibility of bringing two heavy ions in contact, thereby making it possible to probe features like the texture of the nuclear surface, and to study nuclear matter under pressures and strains that are only found in the extreme phase of cosmic evolution as, for instance, in the formation of a neutron star.

In his book, Peter E. Hodgson makes a serious atttempt at covering most of the subjects of the new and rapidly developing field of heavy ion reactions Chapter 2 deals with the ion–ion potential Chapters 3, 5, 6, 7 and 8 deal with the phenomena that can arise in gentle collisions, when the two nuclei barely touch each other (elastic and inelastic scattering and particle transfer reactions, that is, grazing collisions) Chapter 9 treats the aspects of gentle collisions associated with intermediate structure. Chapters 4 and 10 are concerned with the phenomena arising when two ions are brought into intimate contact, and where large amounts of energy and angular momentum are transferred from the relative motion to the internal degrees of freedom, leading to fusion processes and to deep inelastic reactions. In the last half of chapter 10 the subject of shock waves and relativistic reactions is briefly reviewed. The book starts with a review of the subject of heavy ion reactions (chapter 1) and concludes with an epilogue which plays both the rôle of a résumé to the book and of an educated guess at future trends and lines of development

The different approaches to all the subjects covered by the book are generously represented, and the referencing, which includes entries up to the first half of 1976, is impressive. These same positive aspects are however also responsible for the fact that this book is a rather confusing catalogue of results more than anything else. In fact, every subject is dealt with by quoting from one or another paper, in many cases not defining even the basic concepts utilised The conclusions of the authors in question are stated without, apparently, worrying whether they are in contradiction, let alone agreement, with something quoted before or after.

For example, in section 2.2 (p97) it is stated, in connection with the contribution of Satchler to the Nashville conference of 1974· "The double-folding procedure has been used with success to analyse the elastic scattering of alpha particles by nuclei, using standard nucleon–nucleon interactions and phenomenological imaginary potentials. When applied to heavy-ion scattering, however, it is found that the doubly folded potential has to be normalised by a factor around 0.5 to fit the experimental data " Ten pages later we read (p108)· "Recent double-folding calculations by Satchler and Love (1976) . . gave potentials agreeing to with 10–20 per cent with those obtained phenomenologically." It is difficult to understand why Hodgson has neglected to tell us that, as a result of the work of Satchler and Love, Christensen and Winther, and Swiatecki *et al.*, we have now achieved a quantitative understanding of the tail of the ion–ion potential, a prerequisite to any further discussion of heavy ion reactions

Another example is provided by the discussion on Coulomb-nuclear interference of chapter 5. In the section which goes under the title of DWBA calculations we read (p272): "The Coulomb-nuclear interference in the inelastic scattering of 72.2 MeV ^{11}B ions by ^{208}Pb . . [is] given quite well by the distorted-wave theory provided the phase of the nuclear excitation form factor is altered by 5° from that given by the collective model." A couple of pages later, in the section on coupled channel calculations, and when quoting the results of Videbæk *et al* on the reaction (^{16}O+^{58}Ni)→(^{16}O(2_1^+)+^{58}Ni) we read that to fit the Coulomb-nuclear interference minimum, multiple step processes have to be invoked. Even so, there remain discrepancies which (p277) "are probably attributable to the neglect of higher-order couplings". Actually, the so-called agreement in the DWBA analysis of the Coulomb-nuclear interference in the reaction (^{11}B+^{208}Pb)→(^{11}B+^{208}Pb(3_1^-)) and the so-called disagreement in the coupled-channel analysis of the reaction (^{16}O+^{58}Ni)→(^{16}O(2_1^+)+^{58}Ni) reflect a rather similar open problem, namely that of the role of multiple step processes in the Coulomb-nuclear interference pattern.

Another weakness of the book is that the priorities given to the different subjects discussed do not, in many cases, reflect their physical relevance. For example, in the middle of section 2.4, in which the calculations of the ion–ion potential are discussed, a method to calculate the imaginary potential is taken up without a word of warning. The subject is given one page (p138) and taken up again under the curious subtitle of: "Other calculations of heavy-ion potentials" (p141); here, another page is spent on it. The fact that the calculation of the imaginary part of the ion–ion potential, assuming it is a well-defined problem, is a formidable task implying the reduction of the full set of coupled equations to a local equation for the probability of the system to remain in its ground state, is not even suggested by the author

One of the most disturbing features of the book is, however, the plain errors it contains—for example, eq. (5.2 3). At first sight it seems we are confronted with the familiar first-order, time-dependent, coupled equations describing the amplitudes associated with the different reaction channels. However, according to the author, these are the equations describing the time evolution of the probabilities associated with each channel. Because of the central role played by the semiclassical approximation in heavy ion physics, this error has serious consequences, both conceptual as well as practical (for example, the incorrect referencing in p265 to standard computer codes)

On p398 the absolute value of the cross section associated with two-nucleon transfer reactions is discussed. The author should have noted that the cross section increases, due to the inclusion of continuum states in the calculation of the corresponding form factors, not by a factor of 25 but rather by a factor of 2. It is correct that in the reference quoted the value of 25 appears. However, in a later publication the same authors acknowledge an error in their computer code, and the new revised value is given. By the way, this value of about 2 is similar to the value found by Feng *et al.*, the reference for which is quoted in p422 of this book, also in connection with the absolute cross section of two-particle transfer reactions It is probably worth noting that an enhancement of the order of 2–4 would be expected from the experience accumulated on this subject in two-particle transfer reactions induced by light projectiles.

According to the cover jacket the book is aimed at graduate students. Let us hope that the excitement which awaits these graduate students entering the field of heavy ion physics, will not be diminished by the rather confusing picture given by this book. □

Ricardo A. Broglia is at the Niels Bohr Institute, University of Copenhagen, Denmark.

Digital image processing

Digital Image Processing and Analysis. Edited by J. C. Simon and A. Rosenfeld. Pp. 513. (Sithoff and Noordhoff: Leiden, The Netherlands, 1977.) $39.50. *Digital Image Processing.* By W K. Pratt. Pp. 750. (Wiley: New York and Chichester, UK, 1978.) £20.80.

IN 1976, a NATO Advanced Study Institute was held at Bonas, in south-western France. *Digital Image Processing and Analysis* contains 38 papers delivered at that meeting, printed from authors' typescripts. Conference proceedings are now commonly produced three or four months after submission of the manuscripts and there really is no excuse for allowing nearly two years to elapse, especially in such a fast-moving field as image processing. There is thus not much in this book that has not already appeared in print elsewhere.

The papers are a mixture of introductory surveys by well known scientists and shorter contributions. Of the former, there is little that is not better set out elsewhere, in textbooks such as Pratt's, for example, or Rosenfeld's own volume (for review, see *Nature* **264**, 142; 1976); of the other papers, a few contain original material—those on recursive filtering in particular—but most of the material duplicates papers published more rapidly and accessibly in journals.

One redeeming feature of the book is the breadth of coverage. Image enhancement and mensuration are covered as well as pattern recognition, and it is certainly healthy to have these intimately related topics in the same volume. Nevertheless budget-conscious librarians can reasonably regard this volume—unlike several other volumes in the NATO ASI series—as dispensable.

Professor Pratt's volume on *Digital Image Processing* is a long and detailed textbook, which has grown out of his image processing course given to electrical engineering students in the University of Southern California. The result of several years' work, it is clear, detailed and authoritative, and—a very valuable feature—the author is aware which topics are difficult to grasp and which can be treated in a reasonably summary fashion. Furthermore, it contains sections on colourimetry and the visual aspects of image appreciation as well as the formal mathematics of image processing. There are sections on image coding and on comparatively recent additions to the field of image processing, such as texture analysis.

The book has the great merit of not only describing the various techniques that are in use but also explaining their purpose and their role in the overall development of this complex subject. As we should expect from a member of the Image Processing Institute, the algebraic aspects of image processing theory are explained clearly and fully but they are not allowed an excessive amount of space.

One criticism can be made, and it is common to most of the recent texts on image processing: the field of electron microscopy, in which the importance of digital image processing has been increasingly recognised during the past few years, is scarcely ever mentioned. This is regrettable, for not only have electron micrographs benefited from some of the techniques described here — originally intended for other types of image—but some quite new procedures have been developed which may well be of interest to students of image processing in general.

This is an extremely well organised and lucid textbook. Despite the author's modest claim that is intended for use as a course text, many workers already familiar with much of the material will find it useful.

P. W. Hawkes

P. W. Hawkes is Maître de Recherches in the CNRS Laboratory of Electron Optics, Toulouse, France.

Magnetospheric physics

Geomagnetic Diagnosis of the Magnetosphere. Physics and Chemistry in Space, Vol. 9. By A. Nishida. Pp.256. (Springer. New York, Heidelberg and Berlin, 1978.)

THE title of this book emphasises the use of geomagnetic data from instruments at ground level for sensing dynamic phenomena occurring far out in the magnetosphere The value of such observations is also stressed in the preface, and the preface explains that the pursuit of this theme has evolved into an "introduction to magnetospheric physics" In both respects the book is successful, demonstrating how magnetospheric physics can be split with only tolerable damage at a timescale of about one second. Although processes typified by anomalous diffusion are important for the slow disturbances, it is not necessary to discuss the mechanisms, which involve higher frequencies

The crudest approximation in plasma physics is hydromagnetics and this provides a useful start Page 1 is indeed a sudden commencement, but coherence persists through to the last pulsating chapter, another hydromagnetic success Much of the intervening chapters is related to reconnection and to particle motion. Dr Nishida has digested a mass of literature on observations and has produced a clear survey, which provides relief after the disjointedness of conference reports Magnetosphere–ionosphere interactions are included and these sections are of particular relevance to observations using the ground-based incoherent scatter technique; this is timely as a large installation, EISCAT, is now being built.

As an introduction to magnetospheric physics this monograph fills a need; it is splendid for new graduate students or others entering the field. It shows the current rapid progress, being made but warnings such as "the problem of the modelling of the dayside reconnection should not be considered to have been settled" are too weak, and more emphasis might have been given to existing controversies. For the substantial research still needed this book will provide a baseline.

J. W. Dungey

J. W Dungey is a Professor of Physics at Imperial College, University of London, UK.

NOW A journal both for specialists interested in method development and researchers looking for new methods to solve biological, biochemical, biophysical and medical research problems.

JOURNAL OF BIOCHEMICAL AND BIOPHYSICAL METHODS

managing editor:
C.F. CHIGNELL
Laboratory of Environmental Biophysics
National Institute of Environmental
Health Sciences
P.O. Box 12233
Research Triangle Park
NC 27709, U.S.A.

associate managing editor:
S. HJERTÉN
Institute of Biochemistry
Biomedical Centre
University of Uppsala
Box 576
S-751 23 Uppsala
Sweden

AIMS AND SCOPE
Journal of Biochemical and Biophysical Methods will publish research papers dealing with the development of methods to solve biological problems. Articles may be concerned either with new methodology or with the significant modification of existing techniques. The scope of the journal is broad, encompassing all methodological aspects of biochemistry, biophysics and molecular biology. Although articles should be written in sufficient detail to allow easy verification they should also be intelligible to a broad scientific audience. In addition the journal will publish a section of short notes describing improvements in methods which, though significant, do not warrant a full-length research paper. Short review articles dealing with recent developments in a particular method or technique that are of interest to a broad scientific audience will also be published. Papers may be submitted to any member of the editorial board. Full instructions to authors may be obtained from the publisher or one of the managing editors.

Fred Hoyle

The Cosmogony of the Solar System

ISBN 0 901426 85 7 xiv + 165pp 8pp colour illustrations Cloth £7.95

In this book a theory of the origin of the Solar System is presented which rests largely on empirical facts, i.e. those of densities, masses and angular moments of the planets. These facts show the traditional view of planet formation to be far too simple. In particular, emphasis is laid on the observed slow rotation of the Sun and the observed very low concentrations of the rare gases in the terrestrial atmosphere.

This discussion proceeds to consider the formation of organic material in the gas cloud which became the Solar System, the aggregation and rotation of the planets, and other relevant topics.

In conclusion, Sir Fred examines the roles of meteorites and minor planets, and the chemical composition of late additions to the Earth and Moon (with particular reference to radioactive materials) together with such controversial issues as the nature of the lunar surface and the cause of plate tectonics. The final topic discussed is the origin of life.

Dictionary of microbial taxonomy

Dictionary of Microbial Taxonomy. By the late S. T. Cowan. Edited by L. R. Hill. Pp.285 (Cambridge University Press: Cambridge and London, 1978.) £12.50.

TAXONOMISTS, who one might suppose ought to be able to tell us what taxonomy is, seem to agree no more about the meaning than on the derivation of the word. *Taxis* means arrangement: de Caudelle in 1813 coined *taxonomie* and can perhaps by now be forgiven the slip of not spelling it *taxinomie* but he did not explain whether the latter half was from *nomia* (distribution), *nomos* (law) or, mixing Greek with Latin, *nomen* (name). To some, taxonomy means systematics, to others the theoretical study of classification, to others still, nomenclature and the codes which regulate it.

The late S. T. Cowan viewed taxonomy as a scientific art intended to bring order to the often untidy processes of biological classification and nomenclature. Taxonomists he saw as artists—capricious, jealous, argumentative, aggressive—while charitably conceding "Some are good and able to make a useful contribution to science". The microbial taxonomist, he felt, should be a systematist dealing equally with classification, nomenclature and identification—"the trinity that is taxonomy". As a medical and public health bacteriologist, Cowan was often engrossed with practical tasks of identification and he forgave but never forgot the pronouncement of the zoologist, E. Mayr, that identification was the lowest job a systematist did.

Cowan's *Dictionary* contains about 1600 entries, with four introductory chapters, one unfinished, and follows his earlier *Dictionary of Microbial Taxonomic Usage*; the editor, Dr L. R. Hill of the National Collection of Type Cultures, contributes sections on numerical taxonomy. About half of the entries refer to terms or practices in the codes of microbiological nomenclature These international codes, of Nomenclature of Bacteria, Botanical Nomenclature (covering fungi and algae), and Zoological Nomenclature (including protozoa), with the Rules of Nomenclature of Viruses (a provisional virological code was not ratified) differ in numerous confusing ways For example, the type of a bacterial species can be and, very sensibly, usually is a living culture maintained in a reference collection, but the type of a fungal or algal species is generally a dried specimen as required by the Botanical Code. The nomenclatural entries explain the terms, meticulously compare the Codes, where they differ, and give references to the relevant Rules or Articles

Other entries are technical terms of taxonomy, classification and descriptive microbiology (mostly bacteriology), biographies of taxonomists, addresses of culture collections and advice on scientific authorship; just a few (for example, "chemostat") have no discoverable relevance to taxonomy

Many are miniature essays, easy to read and rewarding to the browser, sprinkled with drily entertaining, semi-heretical asides which, for those who did not know Dr Cowan, will convey a flavour of his acrid and sometimes whimsical philosophy. The *Dictionary* is prefaced with an aphorism: "The serious student of nomenclature and the student who takes nomenclature seriously—these are two quite different people", which reads like a 24-carat hand-turned Cowanism but nicely hints that both types of reader should find the book of value—and they will.

J. E. Smith is Professor of Microbiology at the University of Surrey, Guildford, UK.

Control of eye movement

The Brain and Regulation of Eye Movement. By A. R. Shakhnovich. Pp. 189. (Plenum. New York, 1978) $30

THERE is an important school of Soviet scientists who have studied eye movement. Matyushkin has described the different muscle fibres of the eye muscles. Yarbus has published his studies on eye movement in the examination of patterns, and Luriya used this technique in the investigation of neurological cases. The author of this book, Dr Shakhnovich, has worked on eye movements, especially in the rabbit, on eye movement in man and on the local cerebral blood flow in man This book is of interest chiefly for his account of Russian work, for though he is aware of western work, mostly of the 1950s and 1960s, there are important omissions.

It is not, however, easy to follow the accounts of his own work. Although one can accept that local increased activity can and does increase the blood flow in the cerebral cortex so that there are sharply defined local increases and decreases in flow, there is no successful attempt to relate these changes to the control of eye movement The illustrations, as Lorrin Riggs remarks in his introduction, are frequently devoid of essential detail of scales and experimental conditions. A little more detail on the technique of recording of eye movement by the Yarbus cap would be helpful, as Yarbus's own account, though admirable, is not readily available here

In many current problems the author has little help to provide. The function of slow contracture fibres in the eye muscles remains obscure, and the question of vision during saccades is not clarified As Riggs also remarks, the elegance of the bioengineering approach to the control of eye movement is not exploited in this book.

It is, however, his account of the literature which is unhelpful. "Stimulation" of unknown technique in poorly defined places does not provide a useful basis for study of the controlling mechanisms of eye movement in the midbrain, and it is difficult to follow his argument on the vexed question of reflex responses to stretch in eye muscles.

Double stars

Double Stars. By W. D. Heintz. Pp. 174. (D. Reidel: Dordrecht, The Netherlands, 1978.) Hardback Dfl.65; $29; paperback Dfl.30; $14.

DOUBLE STARS in the sky represent objects of great interest to the astronomer—not only because of their prodigious abundance (more than three-quarters of all stars around us seem to be multiple), but also because a symbiosis of their components provides the best data with which to document our theories on stellar evolution. Observations (positional photometric, spectroscopic) of binary systems have provided almost all we know on the masses and absolute dimensions of the stars, and, in addition, have enabled us to gain more subtle empirical insights into their structure.

In spite of these facts, the students of this important branch of astronomy have so far been served none too well by the existing contemporary literature. For this reason alone the appearance of the book under review is to be welcomed, because in many aspects it usefully fills a noticeable gap. However, this welcome cannot be extended to it without reservation concerning certain parts of its contents, where the latter falls short of the actual needs.

The present reviewer has nothing but praise for the first half of the book concerned with wide (visual or astrometric) binaries—a field in which its author is a recognised expert. That part of its text presents the first comprehensive picture of the field since R. G. Aitken's *Binary Stars* of 1935 (Dover reprint, 1964), brought up-to-date by an account of more recent developments (such as the use of electronic cameras, speckle interferometry, and so on). All this should be very useful to the student and researcher alike—not only by what it describes, but also by many references to the original sources which can guide its user in further reading.

With his account of the close (that is, spectroscopic and photometric) binaries, contained in the second half of the book, the author has been somewhat less fortunate—perhaps because its contents constitute largely a second-hand report which is in many places quite out of date. Thus, on the methodical side (determination of the elements) it does not go really beyond what one could find in Aitken's 1935 classic: Had there been no developments of the subject since that time, would it have been worthwhile to write another book about it? Of course they were; and some of them spectacular; but the author went past them without much notice.

Thus, the reader of Heintz's book will not learn much from it alone on the effects of distortion (or reflection) on the determination of masses or absolute dimensions of stars constituting close pairs. He will not learn that the process of "rectification" of their light curves represents an empirical make-shift, without theoretical justification, which is apt seriously to falsify the original light message. Hydrodynamical phenomena (gas streams) in close binary systems are still treated in terms of particle mechanics (in which the pressure is ignored); and photometric effects are ascribed to them without appropriate inquiry as to the density of gas which could possess the requisite optical depth.

Moreover, in the last part of the book, the reader is being exposed to various evolutionary 'scenarios' without sufficient caution about their uncertainty or hypothetical nature. This part of the book is certainly not a safe guide for the uninitiated. However, if it succeeds in making him at least interested enough in this field to follow it up by further reading (or work) of his own, it will have satisfied a very useful aim.

Zdeněk Kopal

Zdeněk Kopal is Professor of Astronomy in the University of Manchester, UK.

Basic introduction to pesticides

Pesticides: Preparation and Mode of Action. By R. Cremlyn, Pp. 240. (Wiley: Chichester, UK, and New York, 1978.) £12

THIS book is aimed specifically at students who are taking first degrees or other qualifications in agriculture or related subjects. It covers, in separate chapters, insecticides, fungicides, herbicides, fumigants, rodenticides, nematicides, molluscicides; and the newer methods of insect control. The basic pattern of these chapters is to start with a brief history of how each particular group of pesticides came to be developed, to give brief details of synthetic routes, and to consider the biological activity.

As with so many agricultural subjects, a wide range of the traditional academic disciplines is involved, from organic chemistry to ecology. The book is obviously written by a chemist: I felt somewhat uneasy with some of the more biological statements. For example, "The nervous system is characteristic of mammals and insects . . . " True, but incomplete, and the uninitiated might wonder which other groups of animals have nervous systems. I am not a professional chemist, but the accounts of synthetic routes seemed to be brief and competent. However, I was less happy with some other aspects of the chemistry. Thus, on p56 DDA is declared to be a metabolite of DDE—as far as I am aware DDA is metabolised only from DDT. Aldrin and dieldrin are both declared (on p64) to be chemically very stable: obviously it depends on how one defines stability, but dieldrin is normally regarded as more stable than aldrin.

These chapters are illustrated with many structural formulae, which are useful, but identification is inconsistent. Some formulae are named, but many which can be identified by short names bear only a number. This number has to be discovered in the text before the identity of an unknown compound is revealed, which is tedious. There are also 28 black-and-white photographs, all taken by well-known manufacturers of pesticides, and mostly of crops with and without pesticide treatment They are of somewhat marginal value.

Two introductory chapters discuss broader issues that apply to the whole range of pesticides. One, on physico-chemical factors, discusses briefly the important topics of pesticide design, formulation and selectivity, application and behaviour of pesticides in the environment. The other covers biochemical reactions that are relevant to the mode of action of pesticides: respiration, photosynthesis, conduction of nerve impulses, transport in plants, synthesis of proteins.

The penultimate chapter considers pesticides in the environment, and crystallised some of the reactions I had experienced from the earlier chapters. Facts are often presented in a slightly misleading way, and often key references are absent. References are indeed rather few in number. They are placed at the end of each chapter, and the same standard texts such as Corbett, Hartley and West, Martin and O'Brien recur frequently. This book is of course more up-to-date than its predecessors, but does not replace them.

In summary, I cannot regard this as an authoritative book, but it may be useful for students who do not want to delve too deeply into any aspect of the subject.

F. Moriarty

F. Moriarty is a Principal Scientific Officer at the Institute of Terrestrial Ecology, Monks Wood Experimental Station, Huntingdon, UK.

Wiley NEW YORK · CHICHESTER

Physicochemical Applications of Gas Chromatography

by **R.J. Laub**, *University College Swansea*,
and **R.L. Pecsok**, *University of Hawaii*.

An up-to-date, critical review of recent advances covering all aspects in a simplified, user-oriented way. The author gives a brief historical review, and compares the technique with classical static methods for obtaining thermodynamic data, emphasising gas chromatography's accuracy and reproducibility. The potential for investigating kinetic phenomena and the properties of pure substances are examined; a comprehensive bibliography is included.

Errors in Practical Measurement in Science, Engineering, and Technology

by **B.A. Barry**, *Manhattan College*.

Covering all the elements of statistical error analysis in measurement this provides a step-by-step presentation of how random errors occur when taking measurements, how these errors behave, how measurement errors can be used to determine the reliability of the values, and how to accord weights to different measurements of the same quantity.

November 1978 200 pages
0471 03156 9 $25.00/£12.35

Measurement of Dissolved Oxygen

by **M.L. Hitchman**, *RCA Laboratories, Zurich, Switzerland*.

A critical assessment of the various aspects of dissolved oxygen measurements that uses a "why" rather than a "how" approach to emphasise physiochemical principles. This book illustrates the monitoring of dissolved oxygen and discusses various situations where a knowledge of oxygen concentration is necessary. *(Chemical Analysis Series Vol. 49)*

The Molten State of Matter:
Melting and Crystal Structure

by **A.R. Ubbelohde, C.B.E., F.R.S.**, *Department of Chemical Engineering and Chemical Technology, Imperial College, London*.

An approach to the study of liquids through the crystalline state of matter and through consideration of what happens to it on melting has become one of the main highways of modern molecular physics. The classical route to the description of liquids by analogy with gases — first explored by van der Waals — is fully effective only for molecules with simple force fields, and not too far from their critical temperature. Very few liquids, amongst the many thousands known, can be adequately described by these quasi-gaseous models. Much more diversified, if more complex, models are feasible starting with the crystals. Because of the enormous range to be covered, in this book on the molten state of matter one aim has been to include what may become effective lines of research in the future, as well as to describe more fully the well-established present developments.

The Physics of Liquid and Solid Helium
Part 2

edited by **K.H. Bennemann**, *Free University of Berlin*,
and **J.B. Ketterson**, *Northwestern University Argonne National Laboratory*.

This continues to examination of the theoretical and experimental results of research on the properties of condensed helium, with major emphasis on ^{3}He and ^{3}He-^{4}He solutions. It discusses the phenomenological theory of the normal state of these two fundamental systems, the superfluid phase of liquid ^{3}He, properties of adsorbed helium films for films ranging from less than a monolayer to the relatively thick saturated film, and neutron scattering in condensed helium. The subjects are presented in a self-contained manner by acknowledged experts in the field. *(Series: Interscience Monographs and Texts in Physics and Astronomy Vol. 29)*

November 1978 760 pages
0471 06601 X $94.00/£45.85

Progress in Inorganic Chemistry Vol. 24

edited by **S.J. Lippard**, *Columbia University*.

The twenty-fourth volume in this series which provides inorganic chemists with a forum for critical, authoritative evaluations of advances in every area of the discipline. This volume contains an up-to-date selection of papers by internationally recognised researchers.

0471 03874 1 $50.00/£25.40

The Chemistry of Heterocyclic Compounds Vol. 33: Chemistry of 1,2,3-Triazines and 1,2,4-Triazines, Tetrazines, and Pentazines

by **H. Neunhoffer**, *Technische Hochschule Darmstadt*,
and **P.F. Wiley**, *The Upjohn Company*.

The thirty-third of these up-to-date, detailed, and comprehensive monographs on the various branches of heterocyclic chemistry. Completeness, with respect to the listing of all compounds and their derivatives described in the literature, has not been attempted in general. The authors endeavour, however, to include all compounds important for reasons of their chemistry, physiological action and medicinal or industrial use, as well as to give ample guidance to the original literature. The monographs are published at irregular intervals and are available individually. *(Chemistry of Heterocyclic Compounds Series)*

November 1978 1364 pages
0471 03129 1 $120.00/£60.00

Thin Films: Interdiffusion and Reactions

edited by **J.M. Poate**, *Bell Laboratories*;
K.N. Tu, *IBM*,
and **J.W. Mayer**, *California Institute of Technology*.

This details the measurement techniques which characterize thin film reactions and their underlying physical and chemical concepts. It provides an understanding of thin film reactions in the context of sub-micron engineering for those concerned with integrated circuits, super-conducting elements, and solar energy conversion structures.

what's new—radioimmunoassay and biochemicals

These notes, prepared from material provided by the manufacturers, are intended to give an outline of the range of products on the market. More detailed information may be obtained by circling the appropriate numbers on the Reader Enquiry Card, bound inside the cover.
A feature on the measurement of radioactivity will appear in the 18 January 1979 issue.

Bethesda Research Laboratories. The BRL sequencing gel electrophoresis system for 34×40 cm gels, comes complete with comb and spacers, glass plates, 12 clamps, platinum electrodes and electrical leads. The support unit measures 17 inches high × 14 inches wide × 15.5 inches deep, overall. The vertical gel support measures 35×43 cm, and features a 22×25 cm cut out facilitating uniform heat dissipation from the sandwich during electrophoresis. The buffer chambers hold approximately 500 ml each. After polymerisation, the gel sandwich slides easily into place forming a liquid-tight seal with the upper buffer chamber by the unique silicone rubber gasket system. The gel dimensions are compatible with standard medical X-ray film, a convenience when preparing autoradiographs.

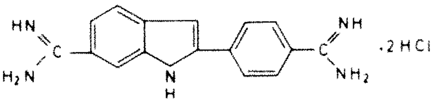
U.C.B. Bioproducts. The U.C.B. Peptide Department specialise in the synthesis of peptides to order. U.C.B. Bioproducts also provide reagents for peptide synthesis such as Merifield resins, protected amino acids (Boc, Z, Fmoc) and rare amino acids (protected or unprotected). Also available are highly characterised antigens and antibodies useful for radioimmunoassay or immunohistological analysis.
Circle No. 46 on Reader Enquiry Card.

Hopkin & Williams supply a wide range of liquid scintillation chemicals for radioimmunoassay. These include: Highly efficient cocktails, PCS (phase combining system) and ACS (aqueous counting scintillant); simple economical Cocktail T—based on toluene, Triton X-100, PPO and POPOP; fluors; scintillation grade solvents; carbon dioxide trapping agent, 2-methoxyethylamine. H&W also manufacture a very large range of high purity zwitterionic biological buffers including HEPES and PIPES which are widely used for tissue culture, analytical and preparative biochemistry and immunology.
Circle No. 47 on Reader Enquiry Card.

Accurate Chemical & Scientific Corporation. The biscationic fluorescent dye DAPI (see below) possesses specific binding properties with adenine-thymine-rich DNA of various origins.



Thus, DAPI will bind differentially to yeast mitochondrial and nuclear DNA forming highly fluorescent complexes and enhancing the separation of such DNAs in caesium chloride gradients. In tissue culture cells DAPI is rapidly taken up into cellular DNA, yielding highly fluorescent nuclei and no detectable cytoplasmic fluorescence. If, however, the cells were contaminated with mycoplasmas, discrete fluorescent foci were readily detected in the cytoplasm and on the surfaces of the cells. DAPI staining of cells infected with vaccinia virus reveals characteristic fluorescent virus 'factories' in the cytoplasm. In a similar way large DNA-virus, phages and bacteria can be stained and in yeast cells petite mutants without mitochondria can be clearly distinguished. Furthermore, trypanosomes and mesenchymal mammalian tissues can be stained. DAPI is soluble in water at $\sim 2.5\%$. Other new products from AC & S include four additions to the range of Dako-Accurate antibodies. (1) Monospecific rabbit anti-human placental lactogen chorionic somatomammotropin. (2) Antibodies to whole sera, rabbit anti-fetal calf serum protein. (3) Antibodies to animal antigens, rabbit anti-horse ferritin (spleen). And (4), horseradish peroxidase conjugated, rabbit anti-guinea pig immunoglobulins.
Circle No. 48 on Reader Enquiry Card.

Bio-Rad Laboratories. Bio-Rad high purity acrylamide and *bis* (*N*, *N'* -methylene-*bis*-acrylamide) are available premixed in the exact proportions needed for forming polyacrylamide gels. Just add water to reagents in the bottle, which is made large enough to hold the stock solution. Three acrylamide/*bis* ratios are available for maximum flexibility. Quality control ensures reproducibility, and the problems of handling the crystalline monomers are entirely eliminated.
Circle No. 49 on Reader Enquiry Card.

Miles. New alkaline phosphatase conjugated antisera to rabbit IgG and to human IgM, for use in enzyme immunoassays and indirect immunohistochemical techniques, are now available from Miles Laboratories Research Products Division. The new antisera have working dilutions of $>$ 1:3000 and $>$ 1:500 respectively. Both products are intended for use in enzyme immunoassay procedures based on the use of antigens or antibodies linked to an insoluble carrier surface. Miles also announce the availability of 15 new antisera for the research and veterinary immunology laboratory. Many are offered commercially for the first time. The new immunoglobulins include antisera to chicken IgM, IgA, and light chains; dog albumin IgM and IgA; horse IgG (T); mouse albumin and alpha-fetoprotein; porcine IgA; rabbit IgG Fab and Fc fragments; and the four rat IgC subclasses, IgG Fab′ fragments and light chains. To meet the need in the clinical veterinary laboratory for species-specific immunological diagnostics Miles have introduced new radial immunodiffusion (RID) kits for measuring canine IgM and IgA.
Circle No. 50 on Reader Enquiry Card.

Bio-Rad. A set of two SDS gel electrophoresis standards covering the ranges, 14,000—68,000 and 45,000—200,000 daltons is now available. The low molecular weight range consists of a mixture of lysozyme, soybean trypsin inhibitor, carbonic anhydrase, ovalbumin and BSA, while the higher range components are ovalbumin, BSA, phosphorylase B, β-galactosidase and myosin. Each kit contains sufficient material for 75 gels and the concentration of each component has been adjusted to give equal staining intensity with Coomassie brilliant blue R250. The SDS gel standards are provided in 5% glycerol, 0.5 m NaCl and 1% SDS at a concentration of 2 mg of each protein per ml. Bio-Rad Six folate standards covering the range 0–20 ng ml^{-1} PGA; nominally zero, 1.0, 2.5, 5.0, 10.0 and 20.0 ng ml^{-1}. These standards should prove useful to laboratories performing microbiological folate assays and those laboratories which prepare their own radioassay test systems. Bio-Rad now offer a comprehensive range of assays in the field of lipid chemistry namely the new Bio-Rad HDL/cholesterol assay, Quantazyme cholesterol, Quantazyme triglycerides and the Bio-Gram A lipoprotein electrophoresis test system.

Steady-State Enzyme Kinetics

Stanley Ainsworth

Identifies the basic ideas of the subject for the graduate and advanced undergraduate student, and familiarises the reader with them so that they may then be applied to any problem likely to be encountered. Although it cannot altogether avoid mathematical presentation, almost all the equations used require only an elementary acquaintance with algebraic manipulation. Moreover the arguments themselves are presented as fully as possible to enable the reader to progress easily from each stage to the next.

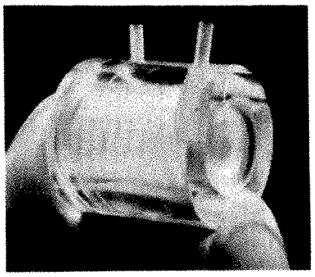
Boehringer Mannheim Biochemicals offer the most frequently requested peptides, including opioids, hypothalamic peptides, pituitary hormones and gastrointestinal hormones. All are stable for at least one year and guaranteed to be biologically active. Boehringer Mannheim now announce a new technique for the purification of DNA fragments. Base-pair specific affinity chromatography of double-stranded DNA is now possible by the use of base-pair specific dyes covalently attached to crosslinked bisacrylamide particles. The (A-T)-specific malachite green gel and the (G-C) specific phenyl neutral red gel are chemically stable materials with opposite base specificity. The DNA components can be successively eluted from a column, according to their base composition, by a sodium perchlorate gradient in a weak phosphate buffer. These affinity materials are convenient for handling and their chemical stability allows for re-use of the same column. Collagenase Dispase contains a highly purified collagenase from *Achromobacter iophagus* and Dispase, a neutral protease. It is a highly purified preparation with clearly defined ancillary protease content. Using purified enzymes offers reproducible tissue dissociation and in contrast to collagenase from *Clostridium histolyticum*, this enzyme mixture does not harm most cell membranes and receptors. The mixture has been used with chicken embryo, thyroid, and fat cells from mouse epididymis.
Circle No. 52 on Reader Enquiry Card.

Collaborative Research Inc. now offer restriction site linkers for recombinant DNA manipulation and cloning studies. The linkers are self-complementary oligonucleotides, each containing the recognition sequences of several restriction enzymes. When joined to DNA by polynucleotide ligase, the linkers add the restriction enzyme recogniton sequence to both ends of the DNA fragment or gene. This fragment can then be inserted by established procedures into a cloning vehicle using the restriction enzyme cohesive termini. Several linkers are available, covering the most widely used restriction enzymes, so it is possible to select an endonuclease for linking which does not cleave the DNA fragment of interest. Collaborative Research linkers are available for *Eco*RI, *Hind*III, *Bam*I, *Pst*I, *Sal*I, *Alu*I, *Xba*I, *Hae*III and *Hpa*II restriction endonucleases. The mitogenic proteins now available from Collaborative Research Inc. include epidermal growth factor, fibroblast growth factor, nerve growth factor, somatomedin, endothelial cell growth supplement, endothelial cell growth factor, human thrombin and human fibronectin.
Circle No. 53 on Reader Enquiry Card.

Technicon Instruments Corporation. The new Technicon bound hexokinase method is for the determination of glucose for users of Technicon SMAC, SMA, and SMA II continuous flow systems. The enzymes used in the assay are bound to the inner walls of a coil which will last at least one month, no matter how many tests are run.
Circle No. 54 on Reader Enquiry Card.



Technicon coil for glucose assay

National Diagnostics. Hydrofluor is a new nonflammable, highly efficient and economical liquid scintillation solution from National Diagnostics. This cocktail has a very low evaporation rate (1/18th that of toluene), to greatly reduce users' exposure to solvent vapours. Hydrofluor is a ready-to-use universal cocktail that will accommodate a wide variety of aqueous and nonaqueous samples, yielding superior counting efficiencies for tritium and carbon-14. Up to 5 ml of an aqueous sample can be incorporated in 10 ml of Hydrofluor.
Circle No. 55 on Reader Enquiry Card.

Prochem. Prochem—the UK based stable isotopes unit of BOC Special Gases—have introduced a list of additions to their range of stable isotopes and labelled compounds. Of particular interest to biochemists is the new range of amino acids available with various deuterium labels, including alanine, methionine and valine. More amino acids are also now available with ^{13}C labelling, including glutamic acid and serine: other ^{13}C compounds offered include barbituric acid and diethylacetamidomalonate—a useful intermediate for amino acid synthesis. New ^{15}N labelled compounds include cyanamides, thiourea and uracil. More multiply-labelled compounds are also now available.
Circle No. 56 on Reader Enquiry Card.

LKB. A new high-speed film for gross autoradiography of low energy emitting radioisotopes like tritium and ^{125}I is available from LKB. Ultrofilm ^{3}H is designed for direct high speed autographic detection of tritium and ^{125}I for autoradiography of tissue sections, electrophoresis and electrofocusing techniques in thin layer polyacrylamide and agarose gels and for paper electrophoresis and thin layer chromatography. Ultrofilm ^{3}H is 12–64 times faster for tritium detection than conventional X-ray films.
Circle No. 57 on Reader Enquiry Card.

Amersham. The supplement to the 1978/79 Amersham Radiochemicals Catalogue lists 35 new products including a number exclusive to Amersham. For example: 1α,25-Dihydroxy[23,24(n)–^{3}H]cholecalciferol, for use in studies of vitamin D; [^{3}H]CI.628, an anti-oestrogen and L-[^{75}Se]selenocystine, for studies of selenium-containing enzymes. New products announced since the supplement went to press include: α-bungarotoxin, *N*[propionyl-^{3}H]propionylated and [^{125}I]iodo-α-bungarotoxin for studies of acetylcholine receptors; methyl-3,5-di[^{125}I]iodohydroxybenzimidate, a unique protein labelling reagent that does not alter the charge on the protein; and 3-[^{125}I]iodohydroxybenzylpindolol for β-adrenergic binding studies.
Circle No. 58 on Reader Enquiry Card.

Cederlane. Cederlane Laboratories have developed a density separation medium designed specifically for the isolation of viable lymphocytes from mouse lymphoid cell suspensions. Lympholyte-M avoids the problems of selective loss of lymphocyte subpopulations which may occur in a normal density separation of mouse lymphocyte suspensions. Lympholyte-M provides a simple and reproducible method of removing red cells and dead cells from spleen, lymph node and thymus cell suspensions. The resulting cell population demonstrates a high and nonselective recovery of lymphocytes. The method is particularly useful for the isolation of spleen lymphocytes, and for the removal of dead cells in sequential cytotoxicity studies. The recovered cells are suitable for use as target cells for cytotoxicity studies, or for *in vivo* and *in vitro* functional studies. Cederlane Low-Tox-H rabbit complement is nontoxic in sensitive assay systems using human target cells, including: assays involving extended incubation times, ^{51}Cr-labelled target cells and highly sensitive target cells (including mitogen-stimulated blasts, lymphoblastoid cell lines, purified B-cells and MLC-stimulated blasts). Low-Tox-H rabbit complement demonstrates high activity and low toxicity in standard microlymphocytotoxicity assay systems.
Circle No. 59 on Reader Enquiry Card.

Research Products International. RPI produce a full range of antisera for radioimmunoassay, affinity chromatography, immunoelectrophoresis and immunodiffusion, including complete pretitered antisera systems for radioimmunoassay. All antisera are subjected to extensive testing for the determination of titre, binding affinity, specicifity, sensitivity levels, affinity constants, binding capacities, incubation condition etc.

FULL PROFESSORSHIP OF BIOCHEMISTRY

available at the

UNIVERSITY OF GENEVA MEDICAL SCHOOL,
Geneva, Switzerland.

Beside demonstrated abilities to lead an active research, the successful candidate should be able to teach in French. Send complete resume to:

Dr. A. F. Muller,
President of the Search Committee,
Department of Internal Medicine,
Hospital Cantonal,
1211 Geneva 4, Switzerland

8818(A)

UNIVERSITY OF READING
LECTURESHIP IN BOTANY

Applications are invited for a Lectureship in Botany Candidates should have special interests in cryptograms or gymnosperms and preferably experience in plant anatomy or embryology.

The person appointed should take up duties on October 1, 1979

Further information may be obtained from the Registrar (Room 214, Whiteknights House), The University, Whiteknights, Reading RG6 2AH, by whom applications should be received not later than January 31, 1979. 8847(A)

UNIVERSITY OF LONDON
Imperial College of Science and Technology

DEPARTMENT OF MATHEMATICS

LECTURESHIP IN MATHEMATICS

The department has a vacancy for a Lecturer in mathematics effective from October 1, 1979 or some mutually agreeable date. The current salary scale is £3,909 to £7,754 plus London allowance £450 per annum

The teaching duties of the Lecturer will include lecturing to students of engineering, including those in the new four-year course, and to students of mathematics

Candidates should have research interests in one or more of the applications of mathematics, in which the numerical and computational aspects of the subject play an essential role. The present interests of the applied areas of the department include theoretical fluid mechanics, continuum mechanics, theory of condensed matter and statistics. Preference will be given to applicants with an interest in one or more of these areas and to younger applicants

Applications (no form) should be sent by February 5, 1979 to Professor J T. Stuart, F.R.S, Department of Mathematics, Imperial College, Queen's Gate, London SW7 2BZ, from whom further particulars can be obtained. 8852(A)

CHROMATIN RESEARCH
BIOPHYSICS LABORATORIES
Portsmouth Polytechnic

RESEARCH ASSOCIATE

required for two years initially, to work in Dr E M. Bradbury's research group. The structure and function of chromatin are studied by both physical and biochemical methods. The group has a high field NMR spectrometer and is actively engaged in neutron and X-ray diffraction work. Experience of one of these techniques, although desirable, is not a prerequisite for appointment However, knowledge of, and some research experience in general biochemical techniques is expected. The successful candidate's project will depend on her/his interests and background.

Salary scale· £3,510 to £3,609 per annum.

Application forms and further details may be obtained from the Staff Officer, Portsmouth Polytechnic, Alexandra House, Museum Road, Portsmouth PO1 2QQ, to whom completed applications should be returned by December 30, 1978 quoting reference S55.

8795(A)

UNIVERSITY OF SIERRA LEONE
Fourah Bay College

Applications are invited for

TWO LECTURERS

for the

DEPARTMENT OF GEOLOGY

Applicants bould have a good honours degree in Geology and postgraduate qualifications preferably at Ph D. level The preferred fields are as follows I) Palaeontology, but candidates should also have experience or interest in Sedimentology and Stratigraphy; II) Tectonics and Structural Geology; but candidates should also have interest or experience in Archaean Geology. In addition to teaching duties, appointees will be expected to develop postgraduate and mapping courses in their subjects and organise and lead field excursions.

Salary Scale. Lecturer, Le3,740 to Le6,270 p.a. (£1 sterling=Le2.10) The British Government may supplement salaries in range £6,054 to £7,170 p a (sterling) for married appointees or £4,020 to £4,926 p a. (sterling) for single appointees (subject to the Government of Sierra Leone's approval—reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Superannuation or contract terms, outfit allowance Le120 (where applicable), car allowance Le600 p a.; annual leave; family passages; car loan negotiated. Part-furnished accommodation at reasonable rental

Detailed application (2 copies) with curriculum vitae naming three referees to be sent direct to Secretary, University of Sierra Leone, Freetown, Sierra Leone, by January 14, 1979.

Applicants resident in the UK should also send a copy to the Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT Further particulars may be obtained by writing to either address.

8856(A)

AGRICULTURAL RESEARCH COUNCIL
PLANT BREEDING AND GENETICS

A vacancy will arise shortly for a

Scientific Adviser

to the Secretary of the A.R.C. Applications are invited from candidates who would like to join the small team of senior scientists which advises him on the scientific aspects of research administration.

The post is graded Senior Principal Scientific Officer with a salary scale of £10,043 to £11,300 plus £465 for working in Central London. Superannuation is under a non-contributory scheme analogous to that of the Civil Service.

The duties of the Adviser will lie in the field of plant breeding of agricultural and horticultural crops including fodder crops and grasses, and the relationship of breeding programmes to the agronomy of field crops and forages. A proved record of research is required, preferably in plant breeding, but candidates whose experience lies in agronomic aspects of the field will also be considered.

Applications from candidates with a good honours degree or equivalent qualifications and a successful record in plant breeding and genetics, should be by letter, accompanied by a full curriculum vitae and the names of two referees.

ARC

Further particulars from Miss M. J. Gard, Agricultural Research Council, 160 Great Portland Street, London W1N 6DT. Closing date January 26, 1979. 8814(A)

MEMORIAL UNIVERSITY OF NEWFOUNDLAND
DEPARTMENT OF BIOLOGY

FISHERIES BIOLOGY

Applications are invited for a position open at senior rank, in the area of Fisheries Biology Candidates must demonstrate a strong record of research and publication in fisheries, and a successful background in supervision of fisheries research at the M Sc. and Ph.D. levels. The successful candidate will play a key role in development of a new fisheries program.

ASSISTANT PROFESSOR—AQUATIC ZOOLOGY

Applications are invited for a position open at the rank of Assistant Professor, in the area of Aquatic Zoology. Enquiries are especially welcome from candidates with specialisation in any of the following areas: marine and freshwater fishes, limnology; planktology; fish population dynamics.

Applicants should submit a curriculum vitae together with the names of three referees. Applications close on January 31, 1979 with Dr G. R. South, Head, Department of Biology, Memorial University of Newfoundland, St John's, Newfoundland A1B 3X9, Canada. 8787(A)

UNIVERSITY OF HONG KONG

Applications are invited for the following new posts which, it is hoped, will be established from September 1, 1979.-

LECTURESHIP/ASSISTANT LECTURESHIP IN PHYSICS

Applicants should have a Ph D degree in physics and be carrying out active research in any field of physics.

STAFF TUTORSHIP IN PHYSIOLOGY

The candidate selected for appointment will be expected mainly to assist in the teaching of Medical Laboratory Science.

Annual salaries (superannuable) are:-

Lecturer; Staff Tutor: HK$63,540 by 4,260 to 72,060 Bar 76,320 by 4,260 to 106,140; Assistant Lecturer: HK$46,260 by 4,320 to 59,220. (£=HK$9.30 approx)

Starting salary will depend on qualifications and experience.

Further particulars and application forms may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or the Assistant Secretary (Recruitment), University of Hong Kong, Hong Kong.

Closing date for applications for all posts is January 31, 1979. 8815(A)

Technicians

Animal Health Laboratories—Production

Two Technicians are required in our recently established production laboratories at Milton Keynes to fill important and challenging posts in the bacterial vaccines production department. The work, which is concerned predominantly with the preparation and purification of bacterial antigens on a large scale, is suitable for persons with either HND, HNC or pass degree qualifications in appropriate scientific subjects and, although prior experience in a microbiological or production field would be an advantage it is not essential, as full training will be given.

Pharmaceutical Research—Drug Analysis

A Technician is required in a research department involved in the development of analyses for new drugs. The department is well equipped with gas chromatography, high pressure liquid chromatography and mass-spectrometry. Experience in any or all of these techniques would be an advantage but training will be given to a suitable applicant.

We are part of a large expanding international company in which salaries and job security are of the high standards to be expected in such an organisation. Other benefits in our employment package include minimum of four weeks holiday, contributory pension scheme with free life insurance, free membership of PPP, flexible working hours, staff restaurant with meal vouchers, sports and social club facilities and contribution to removal expenses where appropriate.

Please write or telephone for an application form to: Adrian Forrest, Hoechst UK Limited, Walton Manor, Walton, Milton Keynes, Bucks. Tel: Pineham 5068.

ST MARY'S HOSPITAL MEDICAL SCHOOL
(University of London)

MEDICAL LABORATORY SCIENTIFIC OFFICER
(Technician)

required in Department of Chemical Pathology to assist with research project of 3 years duration, on oestrogen metabolis in post-menopausal women Work will involve some isotope studies and some radioimmunoassay. Commencing salary within range £3,261 to £3,813 plus £354 per annum London Allowance Apply, The Secretary, at above address quoting Ref. MLSO/CP/N.

8831(A)

TRINITY COLLEGE DUBLIN
GENETICS DEPARTMENT

RESEARCH FELLOW

A postdoctoral fellow is required for studies on the control of cell division in yeast, supported by a training grant from the Medical Research Council of Ireland Salary is £3,300 per annum tax free.

Applications with curriculum vitae and the names of two referees to Dr B L. A Carter, Genetics Department, Trinity College, Dublin 2, Ireland.

8805(A)

STATE OF KUWAIT
KUWAIT UNIVERSITY

Applications are invited for academic posts at Kuwait University. Contracts for two years renewable for a further period of four years if convenient to both applicant and the University.

Applicant should be.—

- a) Holder of Ph D. degree or its equivalent in the respective specialisation.
- b) Holder of an academic post at present in an accredited university or research centre

It should be noted that:—

- — Teaching in English is *a must.*
- — Method of teaching at Kuwait University is based on the credit system.

Field of specialisation —

Botany and Microbiology Department· Virology

Geology Department· Environmental Geology/Geomorphology.

Qualifications include experience in teaching environmental Geology and Geomorphology and willingness to participate (on rotating basis) in instructing elementary courses in marine, geostatistics and introductory geology The candidate will be expected to assist in developing research programmes in Geology and teaching in the Graduate School which opens shortly.

Rank and salary will be determined according to present position, qualification and years of experience.

Monthly total salaries are in the range of.—

Lecturer (U.S. Asst. Professor): K.D 460 to K D. 550

Asst. Professor (U.S. Assoc Professor): K.D 575 to K.D. 665.

Professor: K.D 665 to K.D. 755.

(One K D. is equivalent to U.S. Dollars 3.5. There is no income tax in Kuwait, currency is freely transferable without any restriction).

Candidates are also entitled to the following privileges —

1. Annual return air tickets to the country of citizenship would be provided to the applicant, his wife and three of his children not exceeding the age of twenty
2. Free furnished accommodation with water and electric supplies.
3. Excess baggage allowance in the vicinity of 30 (thirty only) kilogrammes for the staff member and 20 (twenty only) kilogrammes for each member of his family shall be incurred by the University, provided these members accompany him upon his joining the service.
4. The staff member shall be entitled to free sea freight allowance of 400 (four hundred only) kilogrammes, provided costs of the said freight for the said cargo do not exceed Kuwaiti Dinars 100 only. This is applied at the beginning and end of the contract.
5. Gratuity at the end of service shall be one month's basic salary for each year spent in the service of the University.

Application and Curriculum Vitae forms are obtainable from the nearest Kuwait Embassy Completed application accompanied by three letters of recommendation, together with a non-returned copy of the candidate's publications should be submitted *directly* to Kuwait University, Department of Administration Affairs, P O Box 5969, Kuwait Short terms contract (e.g. sabbatical, visiting, etc., will also be considered.

8838(A)

UNIVERSITY COLLEGE CARDIFF
DEPARTMENT OF PHYSIOLOGY

LECTURER IN PHYSIOLOGY

Applications are invited from those qualified in medicine, dentistry, physiology, or related disciplines for a Lectureship to begin on April 1, 1979 or as soon as possible thereafter The salary will be within the non-clinical lecturer range, with membership of U.S.S , at a starting point determined by the applicant's age and experience: £3,883 to £7,754 (medically qualified applicants normally at not less than 3rd point on scale).

Applications (2 copies), together with the names and addresses of two referees, should be forwarded to the Vice-Principal (Administration) and Registrar, University College, P O Box 78, Cardiff CF1 1XL, from whom further particulars may be obtained Closing date January 16, 1979. Please quote reference 1659. 8816(A)

UNIVERSITY OF MELBOURNE
LECTURESHIP
in the
DEPARTMENT OF OPTOMETRY

Applications are invited for the above-mentioned position in the Department of Optometry of the University of Melbourne.

Applicants should have a higher degree and a demonstrated capacity for research. The field of interest in which the appointment will be made is open. Applications are therefore sought from optometrists with interests in either the clinical or pre-clinical sciences, from physicists with post-graduate training and experience in optics, and from physiologists with developed interests in the neurobiology of vision.

SALARY: $A15,179 to $A19,940 per annum.

Enquiries about the Department may be directed to the Chairman, Professor B L Cole, in the University

Further information, including details of application procedure and conditions of appointment, is available from the Registrar, University of Melbourne, Parkville, Victoria, 3052, Australia, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications close on February 28, 1979. 8785(A)

CITY OF BIRMINGHAM POLYTECHNIC
Faculty of Engineering and Science
DEPARTMENT OF SCIENCE

PRINCIPAL LECTURER
in
BIOMEDICAL SCIENCES

required to contribute to the teaching of courses in Medical Laboratory Sciences and Biological Sciences and to make a significant contribution to the development of Medical Laboratory Science Courses in the Science Department.

Candidates should have suitable academic qualifications together with experience of teaching at degree level, and will be expected to contribute to research programmes within the department.

An ability to contribute to the teaching in one or more of the following areas of study would be an advantage: Virology, Immunobiology, Genetics, Cell Biology, Serology.

Salary Scale: Principal Lecturer: £7,047 to £7,818 (bar) to £8,844.

Further details and application forms (to be returned by January 5, 1979) from: The Personnel Officer, City of Birmingham Polytechnic, F Block, Perry Barr, Birmingham B42 2SU. (021-356 6911 Ext. 217). 8786(A)

THE PAPUA NEW GUINEA UNIVERSITY OF TECHNOLOGY

CHAIR OF FORESTRY

Applications are invited for the Chair of Forestry and Head of Department of Forestry in the University of Technology, Lae, which will fall vacant at the end of 1978.

DUTIES AND RESPONSIBILITIES:— The successful candidiate will be responsible for continuing the development of the Forestry degree course, for the formulation and carrying out of an applied research program in the Department, and for maintaining the closest links with the national forest service and with the forest-based industry. The basic degree course, started in 1975, is now well-established but may need to be evaluated and modified to meet the relevant and changing requirements of a developing Papua New Guinea.

Applicants must have a postgraduate qualification and considerable experience and expertise in tropical forestry, particularly in integrated land-use in the tropics, and must have appropriate teaching, research and administrative experience in a developing country. Academic calibre should be demonstrated by research and publications.

SALARY AND CONDITIONS OF SERVICE:— The salary will be that of a Professor K20,460 per annum. Allowances additional to salary are payable as follows:— Married K2,300 per annum; single K1,300 per annum. In certain circumstances a child allowance of K156 per annum is also payable. An additional allowance and additional fares may be provided for children being educated away from their parents' place of residence. Other benefits include furnished housing (hard goods only) supplied at nominal rental, leave fares to place of recruitment every second year and equivalent fares to Canberra, Australia, each alternate year and six weeks annual leave. Superannuation benefits apply in most cirmustances. Appoinment will be on a contract basis for a maximum of six years. Terms and conditions of service are currently under review.

APPLICATIONS:— Applications should comprise a full curriculum vitae including particulars of age, nationality, marital status, dependents, qualifications, experience, publications and also the names and addresses of three referees from whom confidential enquiries can be made.

Photo copies of certifying documents should be submitted with the applications addressed to the Registrar to reach this office by February 2, 1979.

Those applying from the United Kingdom should also submit a copy of their application to the office of the Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF.

Further information is available from the offices of the A.C.U. or from the Registrar of the University.

The University reserves the right to make no appointment or to make an appointment by invitation at any stage.

The Registrar
The Papua New Guinea University of Technology

UNIVERSITY OF SOUTHAMPTON

Computer Studies Group

Research into Relational Databases

Over the last 5 years a relational database management system (RDBMS) has been developed in prototype form by a joint team from ICL, the BBC and Southampton University. A three year research project to investigate and improve the efficiency of the RDBMS system has been financed by the Science Research Council, and applications are invited for the posts of RESEARCH FELLOW and RESEARCH ASSISTANT to work under the direction of Professor D W Barron. Candidates should preferably have a first degree in Computer Science and must have experience of programming in a language such as Pascal, Coral 66, Algal W or Algol 68. For the Fellowship a Ph D in a relevant branch of Computer Science, or extensive relevant experience, is required.

Salary: Research Fellowship from £3,883 (Scale 1A)
Research Assistantship from £3,384 (Scale 1B)
according to qualifications and experience.

Further particulars are available from Miss E C P Roberts, Staffing Section, The University, Southampton SO9 5NH.

COMMONWEALTH MYCOLOGICAL INSTITUTE

FERRY LANE, KEW, SURREY

Vacancies for

FOREST MYCOLOGIST and PLANT PATHOLOGIST

THE FOREST MYCOLOGIST will work on the fungal pathogens of Central American pines, in a post funded by the UK Ministry of Overseas Development, for a period of three years.

The successful candidate will be based at the Commonwealth Mycological Institute, but will be required to make annual collecting visits to Central America to survey and collect fungi associated with pines.

Qualifications: A good honours degree with postgraduate experience involving work on the identification of fungi. Experience in forest pathology will be an advantage.

THE PLANT PATHOLOGIST will work as a Liaison Officer under the UK Ministry of Overseas Development, based at the Commonwealth Mycological Institute.

He will assist developing countries on behalf of ODM with the identification of pathogens of forest trees; advise on control methods and supply information of current interest on forest pathology; conduct short-term surveys and make advisory visits overseas. He would be expected to contribute to the work of the Commonwealth Mycological Institute.

The post forms part of a small team comprising two Liaison Officers and two ancillary staff.

Qualifications: Preference will be given to a forest pathologist with knowledge of plantation problems. Tropical experience is essential.

Salary, FOR BOTH POSTS, in the scale £2,839 to £8,461 (which is subject to revision). Starting salary according to age, qualifications and experience.

Application forms, and further particulars, obtainable from: The Executive Director, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN.

Closing date for applications: February 12, 1979. 8844(A)

UNIVERSITY OF LONDON

CHAIR OF MATERIALS AT IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

The Senate invites applications for the above Chair, tenable in the Department of Metallurgy and Materials Science.

The Professor of Materials will take a leading part in teaching, curriculum development at the undergraduate and postgraduate levels and in initiating research. It will be an important function of the Chair to foster cooperation in the subject with other Departments of the College and to maintain links with industry.

Applications (10 copies) must be received no later than February 16, 1979 by the Academic Registrar ( ), University of London, Senate House, London WC1E 7HU, from whom further particulars should first be obtained. 8784(A)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the post of postdoctoral Senior Research Assistant in the Department of Biochemistry. The post is funded by a grant from the North West Cancer Research Fund to study the hormone responsiveness of a line of human breast cancer cells. Experience of tissue culture would be an advantage.

The initial salary will be within the range £3,883 to £4,882 per annum (Senior Research Assistant 1A). The appointment will be for one year in the first instance.

Applications, together with the names of two referees, should be received not later than January 12, 1979, by The Registrar, The University, Liverpool L69 3BX. Quote Ref. RV/422/N. 8833(A)

UNIVERSITY OF SURREY

DEPARTMENT OF METALLURGY AND MATERIALS TECHNOLOGY

Applications are invited for the post of Redland Research Fellow tenable in the Department of Metallurgy and Materials Technology at the University of Surrey.

The research programme carried out by the Fellow will relate closely to the research and development interests of Redland Limited, and the Fellow normally carries out a number of subsidiary investigations requested by the Company's Research and Development Centre. The post affords an excellent opportunity for the incumbent to familiarise himself with industrial research and to make the transition from academic to the industrial environment.

Applicants should have a Ph.D. or equivalent experience in some area of material science, or solid state chemistry. Preference may be given to candidates with interests or experience in silicate chemistry, Portland cement and ceramics. In view of the nature of the appointment, candidates having the ability to formulate new experimental approaches to unresolved problems would be preferred. The Fellow appointed will undertake research in materials of interest in construction and building and the main concern will be with property structure relationships of interest in developing new or improved materials.

The appointment would be made for two years and can be renewable.

Remuneration will depend on age and experience and will be in the range £3,883 to £4,382 (under review), on scales related to the University lecturer scales. Applications, from men and women, in the form of a curriculum vitae, with the names and addresses of three referees, should be sent to:

Professor J. E. Bailey,
Department of Metallurgy and
Materials Technology,
University of Surrey,
Guildford,
Surrey GU2 5XH 8791(A)

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF BIOCHEMISTRY

RESEARCH TECHNICIAN

(Grade 3)

required for Monoclonal Antibody Production and Biochemical Investigations of Erythrocyte Proteins, particularly those affected by Heredity Spherocytosis, to work in a new well-equipped reserch group investigating cell membrane diseases. A sound biochemical background and previous experience in tissue culture, protein chemistry, electrophoresis and/or chromatography are disirable.

The appointment is from January 1, 1979 initially until July 31, but extendable subject to continuing support from granting agencies, at a starting salary of £3,153 (under review) including London Weighting.

Write or telephone soon for an application form to the Departmental Superintendent, Biochemistry Department, Imperial College, London SW7 2AZ. Tel: 01-589 5111 Ext. 1119, quoting reference DMS RT3.

8713(A)

POSTDOCTORAL POSITION

(funded by the
Cancer Research Campaign)

available for a 3-year study of the role of proteinase inhibitors in the prevention of tumour invasion. A background in cancer research or cell biology would be advantageous, but not essential.

Salary on M.R.C. Scale II, up to £4,631 p.a.

Applications, with curriculum vitae and the names of two referees should be sent to:

Administrative Secretary,
Strangeways Research Laboratory,
Wort's Causeway,
Cambridge. 8845(A)

UNIVERSITY OF RHODESIA
School of Agriculture
DEPARTMENT OF LAND MANAGEMENT

TWO LECTURESHIP vacancies, one in SOIL CHEMISTRY and one in SOIL PHYSICS, exist in the newly-established Department of Land Management, School of Agriculture and applications are invited for these posts.

Depending on qualifications and experience appointments will be made at Lecturer or Senior Lecturer level.

SALARY SCALES (approx sterling equivalent) Senior Lecturer, £7,609 to £10,059, Lecturer Grade I, £6,902 to £7,942, Lecturer Grade II, £4,260 to £6,681

Both Permanent Pensionable Terms and Short-term Contracts are available

Further particulars and application procedure from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Closing date for receipt of applications: JANUARY 15, 1979

British subjects considering applying for posts in Rhodesia are urged to consult the Foreign and Commonwealth Office (telephone 01-233 8727) or their nearest British Consular Office.

8857(A)

COMMONWEALTH AGRICULTURAL BUREAUX
Vacancy for
SCIENTIFIC INFORMATION OFFICER
at the
Commonwealth Bureau of Plant Breeding and Genetics

Department of Applied Biology
Cambridge CB2 3DX

Duties include scanning the world literature dealing with the breeding, genetics and cytology of economic plants, preparing abstracts for publication in **Plant Breeding Abstracts**, and answering enquiries within this field

Qualifications. A degree either in botany, agriculture or genetics or in German is required Applicants combining scientific and linguistic aptitudes will receive prior consideration. Capability to read foreign languages other than German will count as additional qualification Ability to write good English is essential.

Salary. The salary is in the scale £2,839 to £5,448 per annum plus a compensatory allowance (taxable but not superannuable) of 3.3% of basic salary to offset personal contribution to superannuation scheme. Starting salary according to qualifications and experience Promotion to higher scales on merit

Application forms and full particulars from Executive Director, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN

Closing date for applications: January 15, 1979 8807(A)

RESEARCH GRADUATE

to undertake studies in relation to human myeloma cultures and their influences on antibody formation etc Prior experience of tissue culture, lymphocyte culture or bone marrow work is preferred. Excellent opportunity for a Ph D thesis (postdoctoral applicants will only be considered if they already have this experience) Salary Whitley A Scale according to experience. Applications, with 2 referees, to Professor J. R Hobbs, Department of Chemical Pathology, 17 Page Street, London SW1P 2AR, by December 18, 1978 8809(A)

UNIVERSITY OF OXFORD, Department of Forestry. A Research Officer is required for a three-year project in Honduras concerned with the ecology and regeneration of Central American pines. Candidates with an appropriate degree and research experience should apply to the Administrator, Department of Forestry, Commonwealth Forestry Institute, South Parks Road, Oxford OX1 3RB before December 31, 1978, from whom further particulars may be obtained A knowledge of the country and some fluency in Spanish would be desirable Salary on University Scale £3,384 to £8,257 (under review) according to age and experience. 8839(A)

PRINCETON UNIVERSITY
DEPARTMENT OF BIOLOGY

Seeks applicants for the position of.

ASSISTANT PROFESSOR

in the field of population biology. Preferential consideration will be given to candidates whose interests overlap and complement those of existing members of Princeton's population biology group Gould, Horn, May and Terborgh Appropriate areas are. the ecology and adaptive behaviour of animals and plants, population dynamics, sociobiology and biogeography Field experience and a wide ranging interest in organisms are desirable qualifications Evidence of exceptional promise in research is essential Teaching duties will consist of one undergraduate and one graduate level course and counselling students in research. Salary competitive, to be negotiated. Applicants should send a curriculum vitae, a statement of research experience and interests, and three letters of recommendation to. Dr John Terborgh, Department of Biology, Princeton University, Princeton, New Jersey, 08540

Equal Employment Opportunity/Affirmative Action Employer, M/F

8783(A)

UNIVERSITY OF WASHINGTON
CHAIRMAN
DEPARTMENT OF GEOLOGICAL SCIENCES

The College of Arts and Sciences invites applications for the position of Chairman of the Department of Geological Sciences The department has a broad teaching and research program leading to B.S., M.S and Ph.D degrees Twenty faculty members supervise the studies of 70 graduate and 140 undergraduate students.

Extensive facilities are available for research in Crystallography, Isotope Geology, Petrology, Quaternary Geology, Remote Sensing and Lunar Geology, and Structural Geology.

Applicants should submit their curriculum vitae, list of publications and names of four references to Professor Dean A McManus, Chairman of the Search Committee, University of Washington, WB-10, Seattle, Washington 98195.

An Equal Opportunity Affirmative Action Employer 8781(A)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF CHEMISTRY
RESEARCH IN RAMAN SPECTROSCOPY AND ELECTROCHEMISTRY

Recently it has become possible to study the molecular processes involved in electrochemical reactions by making *In situ* Raman spectroscopic observations The pioneer work in this field was carried out in this Department, and an expansion of the effort is planned. We wish to appoint two postdoctoral research fellows as soon as possible

Applications are invited from researchers experienced in vibrational spectroscopy and/or electrochemistry Salary on grade 1A (£3,883 to £6,555)

Further details can be obtained from Dr P. J. Hendra or Professor M Fleischmann on 0703 559122, ext 597 or 371, or by writing to the Department of Chemistry, The University, Southampton SO9 5NH Please quote ref. MH1/2/Na. 8789(A)

THAI NATIONALS

Faculty positions available for graduates in biochemistry or related fields. Good opportunity to join a young dynamic department with active programs in research (currently: nutrition, reproduction and tropical diseases) and teaching (medical and postgraduate students) Special consideration to those trained in biotechnology, cancer and endocrinology. Send curriculum vitae to **Chairman, Department of Biochemistry, Faculty of Science, Mahidol University, Rama VI Rd., Bangkok. Thailand.**

8717(A)

We have an immediate vacancy in the London office for a

PHYSICAL SCIENTIST

preferably one who has some postdoctoral experience. He or she would be engaged largely in the assessment of scientific manuscripts submitted for publication but would probably also help with other sections of the journal. Experience in the earth, ocean or atmospheric sciences would be an advantage.

Write to:
The Editor
NATURE
MACMILLAN JOURNALS LIMITED
4 Little Essex Street, London WC2R 3LF
enclosing a curriculum vitae and any other material you consider relevant.

8661(A)

THE AUSTRALIAN NATIONAL UNIVERSITY
Research School of Chemistry
RESEARCH FELLOWS

Applications are invited for appointment as postdoctoral Research Fellow in the Research School of Chemistry. Appointments will be for two or three years and may be made in any area of chemistry Current major research interests in the School are:-

Organic Chemistry: (Professor A. J. Birch, Mr R. W. Rickards, Dr J. K MacLeod, Dr L. N Mander) including organic chemistry of biologically active compounds; synthetic organic chemistry, organometallic chemistry in organic synthesis, metal-ammonia reduction studies.

Inorganic Chemistry: (Professor A M. Sargeson, Dr M. A Bennett, Professor B G. Hyde (to arrive)): including synthesis, structure and reaction mechanisms of transition metal complexes; biomimetic chemistry and organotransition metal chemistry, solid state inorganic chemistry

Physical and Theoretical Chemistry: (Professor D P Craig, Dr J. Ferguson, Dr R Bramley, Dr T. R Welberry). including molecular and crystal theory, solid state spectroscopy; photophysics, disordered materials

Theoretical Organic Chemistry Dr L. Radom.

Mass Spectrometry: Dr J. K MacLeod: organic and biological applications, ICR spectrometry

X-ray Crystallography: Dr G B Robertson.

Analytical Chemistry: Miss B J Stevenson.

Appointments will be made primarily within these research groups, but proposals for independent research in areas which complement existing programmes will also be considered.

The School is non-departmental and is well equipped to contemporary standards

Salary on appointment will be in accordance with qualifications and experience within the range of $A15,179 to $19,813 per annum, Australian currency. Current exchange rates $A1 : 58NP : $US1.14

Reasonable travel expenses are paid and assistance with housing is given for an appointee from outside Canberra. Superannuation benefits are available

The University reserves the right not to make an appointment or to make an appointment by invitation at any time

There is no application form Applicants should supply to the undersigned by **February 23, 1979** a curriculum vitae, list of publications and statement of research interests, together with two passport-sized photographs, the names and addresses of three academic referees and the probable date on which the postdoctoral Research Fellowship, if awarded, could be taken up.

G E. Dicker,
Academic Registrar,
P.O Box 4,
Canberra, ACT, 2600,
Australia

8832(A)

City Hospital

BASIC GRADE CYTOGENETICISTS

Applications are invited for two posts as Basic Grade Cytogeneticists in the South Trent Sub Regional Cytogenetics Service.

Applicants should have an Honours Degree in Genetics or some other Biological Science.

Preference will be given to candidates with previous experience in diagnostic chromosome analysis or tissue culture. Whitley Council Salary and conditions of service.

Further details and application forms available from: Personnel Services, Valebrook House, Sherwood Hospital, Hucknall Road, Nottingham. Telephone: (0602) 625459 anytime.

Closing date: 5th January 1979. **8824(A)**

NORTH NOTTINGHAM HEALTH DISTRICT (T)

Nottinghamshire Area Health Authority (Teaching)

University College, Galway, Ireland

RESEARCH ASSISTANT

Applications are invited from graduates in Physiology, Biochemistry or allied subjects to study the metabolism of glutamine in isolated segments of kidney tubules. The research is supported by the Medical Research Council of Ireland.

Applications should be sent to: Professor D. J. O'Donovan, Physiology Department, University College, Galway, Ireland, **not later than December 18, 1978.** 8797(A)

CHARING CROSS HOSPITAL MEDICAL SCHOOL

(University of London)

RESEARCH TECHNICIAN

required to work on the development of methods for diagnosis and monitoring of patients with cancer. Experience in protein chemistry or immunology would be an advantage. Post vacant January 1, and the appointment will be for 21 months.

Salary range: £3,261 to £4,680 plus £354 London Allowance.

Further details obtainable from Dr R. Begent, tel: 01-748 2040, extn 2087, and application forms from The Secretary, Charing Cross Hospital Medical School, The Reynolds Building, St Dunstan's Road, London W6 8RP. (Ref: 450/1.) 8850(A)

UNIVERSITY OF OXFORD UNIVERSITY LECTURESHIP IN ELEMENTARY PARTICLE PHYSICS

Applications are invited for the above post. Stipend according to age on the scale (under review) £3,883 to £8,257. The successful candidate may be offered a tutorial fellowship by Hertford College (for either a man or a woman). Details of both appointments may be obtained from:

Professor K. W. Allen, Department of Nuclear Physics, Keble Road, Oxford OX1 3RH, to whom completed applications (one typed copy) and the names of 3 referees should be sent by February 15, 1979. 8810(A)

McGILL UNIVERSITY

Faculty of Medicine

DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS

DEVELOPMENTAL PHARMACOLOGY

Applications are invited from a senior faculty position from individuals interested in directing a multidisciplinary group in this area of research. The group is guaranteed adequate research space and facilities, a generous operating budget and sufficient monies for clinical and non-clinical investigators as well as support personnel. Curriculum vitae, bibliography, résumé of current research activity and interest and names of three referees should be sent to Dr R. I. Ogilvie, Chairman, Department of Pharmacology and Therapeutics, McGill University, 3655 Drummond Street, Montreal, Quebec, Canada H3G 1Y6. 8820(A)

POSITION OPEN

Postdoctoral position available immediately for individual with background in biochemistry or cellular genetics. Studies involve somatic cell genetics, purine metabolism, nucleic acid synthesis and recombinant DNA technology. Salary $11,000. Contact: Dr Milton Taylor, Department of Biology, Indiana University, Bloomington, IN 47402. An Equal Opportunity/Affirmative Action Employer. 8821(A)

UNIVERSITY OF THE SOUTH PACIFIC

Applications are invited for the post of

UNIVERSITY FELLOW

in the INSTITUTE OF MARINE RESOURCES (Post 78/75). This vacancy exists at the newly established Atoll Research Unit. This unit is to be located on Tarawa, in the Gilbert Islands. The appointee will be initially required to develop and carry out where practicable the applied research and advisory and educational programmes of the Unit, in consultation with the director of I.M.R. The most immediate project to be undertaken by the appointee is a survey of Tarawa lagoon and subsequent monitoring of any existing pollution indices. The appointment will be made at lecturer or senior lecturer level. Housing and some laboratory facilities are available. An appropriate vehicle for transportation on Tarawa will be provided. Salary Scales: Senior Lecturer F$11,178 to F$13,209 per annum; Lecturer F$7,640 to F$10,808 per annum (salary scales are curerntly under review). (£1 sterling=F$1.62.) The British Government may supplement salary in range £1,842 to £2,796 per annum (sterling) for married appointee or £444 to £1,164 per annum (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. In addition, the University provides 15% gratuity, superannuation contribution, appointment allowance, partly furnished accommodation at maximum rental of 12½% of salary (under review), family passages. Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Registrar, University of the South Pacific, P.O. Box 1168, Suva, Fiji, by January 22, 1979 quoting post reference number. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 8855(A)

THE UNIVERSITY OF MANCHESTER

TEMPORARY LECTURER IN RADIOCHEMISTRY

Applications are invited for this one-year post starting as soon as possible.

Salary range £3,883 to £4,631 p.a.

The radiochemistry group in the Department of Chemistry consists of another member of staff, two post-doctoral fellows and eight postgraduate students. There is a wide range of research topics including nuclear reaction studies, activation analysis and radiation effects in solids. The appointee would play an active role in the teaching and research activities of the group.

Particulars and application forms (returnable by January 6) from the Registrar, The University, Manchester M13 9PL. Quote ref: 270/78/N. 8843(A)

UNIVERSITY OF BRISTOL

DEPARTMENT OF BACTERIOLOGY

VIROLOGY RESEARCH ASSISTANT—RANGE 1A

A vacancy exists for a Research Assistant for a period of 21 months to undertake investigation into the RNA biochemistry of measles virus in chronic infections. The preferred applicant would be a postdoctoral biochemistry graduate with particular experiences of nucleic acid (especially RNA) techniques.

The post is M.R.C. funded and the commencing salary will be up to £4,133 per annum (scale under review).

Applications, citing two referees, should be forwarded to Dr L. W. Greenham, Department of Bacteriology, University of Bristol BS8 1TD. 8846(A)

THE WEST OF SCOTLAND AGRICULTURAL COLLEGE AGRONOMY SPECIALIST

Applications are invited for the above post in Agronomy Department tenable for three years, within a group responsible for the evaluation of sewage sludge as a fertiliser for grassland. The duties will be primarily concerned with overseeing the planning and conduct of field performance trials in which comparisons are made between sludge and conventional fertilisers. Duties would also include literature review, preparation of data for publication and the writing of advisory literature.

Candidates should have an honours degree or equivalent qualification in grassland/crop production or related discipline, or a higher degree, and a special interest in experimental work. The appointee will be based at Auchincruive but appreciable travel is involved and a current driving licence is essential.

The starting salary will, according to age, qualifications and experience, be on one or other of the following scales:-

Grade IV—£2,998 (Honours—1st or 2nd Class—£3,167) rising to £3,924.

Grade III—£4,178 rising to £6,898.

Conditions of appointment and application forms are available from the Secretary, The West of Scotland Agricultural College, Auchincruive, Ayr KA6 5HW, with whom applications should be lodged not later than January 5, 1979. 8837(A)

UNIVERSITY OF ABERDEEN

DEPARTMENT OF BIOMEDICAL PHYSICS AND BIOENGINEERING

RADIATION PROTECTION OFFICER

Applications are invited from PHYSICISTS for the above post carrying duties throughout the University and with certain service commitments to hospitals in the Grampian, Orkney and Shetland areas. Graduate technical and secretarial assistance is provided. The successful candidate will be expected and encouraged to participate in the general activities of the Department including teaching and research.

Salary on Lecturer Scale £3,883 to £7,754 per annum, with appropriate placing. Superannuation benefits.

Further particulars from The Secretary, The University, Aberdeen with whom applications (2 copies) should be lodged by January 12, 1979. 8836(A)

UNIVERSITY OF OXFORD UNIVERSITY LECTURESHIP IN BIOCHEMISTRY

Applications are invited for the above post for appointment from October 1, 1979, Stipend according to age on the scale £3,883 to £8,257 p.a. Other things being equal, preference may be given to candidates with research interests in nucleic acid chemistry, carbohydrate chemistry, immunology, or bioenergetics. The successful candidate may be offered appointment as an official fellow and tutor at St Catherine's College (open to men and women). Further particulars of both the University and college posts may be obtained from Professor R. R. Porter, Department of Biochemistry, South Parks Road, Oxford OX1 3QU. Applications for the lectureship (eight typed copies, one from overseas candidates) including the names of three referees should be sent to Professor Porter by January 31, 1979. Applications for the college fellowship should be sent to The Master, St Catherine's College, Oxford OX1 3UJ by the same date. 8811(A)

EDUCATION OFFICER

required by the Sussex Trust for Nature Conservation for development of educational activities, including servicing of Woods Mill Educational Centre. Starting salary £3,300 to £3,500. Car ownership essential. Details and application form from The Administrative Officer, S.T.N.C., Woods Mill, Henfield, West Sussex. 8808(A)

LIVERPOOL POLYTECHNIC
DEPARTMENT OF BIOLOGY
RESEARCH ON DEVELOPMENT OF CONTAMINATED LAND
(3 posts)

This is a long-term contract undertaken for and funded by the Department of the Environment to establish optimum soil cover and ameliorant treatments for reducing the uptake of cadium and other trace metals by vegetables and soft fruits from contaminated land intended for housing. The Project is based in Liverpool, with a permanent research site at a former Sewage Farm near Leicester.

In conjunction with the establishment of the Project, three posts are offered: —

1. POSTDOCTORAL RESEARCH FELLOW

To assist in the overall direction and formulation of the study, including day-to-day control of the research work; the assessment of analytical and other data and the preparation of regular Project reports. The appointee will be responsible for the analysis and interpretation of materials collected from the main experimental plots. He/she will also be required to liaise effectively with the Site Officer, and to assist the Project Director in plotting the overall course of the study. Frequent visits to Leicester will be involved, but the appointee will be based in Liverpool. A current driving licence is essential.

QUALIFICATIONS: The successful candidate should possess a Ph.D. in an appropriate botanical or agricultural field, and should, if possible, have previous experience in field trials.

Salary scale: £4,101 to £6,558 p.a.

2. SITE OFFICER

The appointee will be responsible for the day-to-day management of the permanent research site, and will be based full-time in Leicester. The duties will include planting, sampling, plot maintenance and supervision of other long-term experiments and ancillary staff. The Site Officer will also be responsible for liaison with contractors during the establishment phase of the research station. It may be possible for a suitable person to register for a higher degree during the course of the Project. A current driving licence is an advantage.

QUALIFICATIONS: A degree or equivalent in Agriculture, Botany, Horticulture or a related field. Some experience of management is desirable.

Salary scale: £3,192 to £5,334 p.a.

3. ANALYST/TECHNICIAN

To carry out analysis in connection with the Project using mainly atomic absorption techniques. Based in Liverpool, but may be required to assist at research site at Leicester in sampling, etc., to meet seasonal peak work-loads.

QUALIFICATIONS: An appropriate degree or related qualification and relevant analytical experience.

Salary scale: £3,192 to £5,334 p.a.

Application forms and further particulars are available from the Personnel Office, Liverpool Polytechnic, Richmond House, 1 Rumford Place, Liverpool L3 9RH. Tel: 051-227 5581, extn 43.

Please quote: Reference LP/250.

Closing date for applications is January 12, 1979. 8862(A)

BEATSON INSTITUTE FOR CANCER RESEARCH
SCIENTIST

Postdoctoral scientist required with immunological experience to join a new three year project using the Hybridoma technique for raising monoclonal anti-bodies to analyse red blood cell development. Please apply to: Dr P. R. Harrison, The Beatson Institute, Garscube Estate, Switchback Road, Bearsden, Glasgow. 8865(A)

NEW ZEALAND
University of Canterbury Christchurch

Applications are invited for the following position:

LECTURER IN EXTENSION STUDIES

Applicants should possess a higher degree in Science. The appointee will be required to carry out teaching, administrative and organisational responsibilities with special reference to an extension programme in science.

Applications close on **January 15, 1979.**

The salary for a Lecturer is on a scale from NZ$11,894 to $14,488 per annum.

Particulars, including information on travel and removal allowances, study leave, housing and superannuation, may be obtained from the Association of Comonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 8830(A)

UNIVERSITY OF LONDON
INSTITUTE OF ARCHAEOLOGY
BOTANIST

required with knowledge of plant taxonomy and anatomy to work on botanical material from archaeological excavations in England. A degree in a relevant subject, familiarity with pollen and seeds and previous archaeological experience would be advantageous.

SKELETAL BIOLOGIST

required for studies on excavated early British human skeletal samples. Candidates should hold an appropriate degree and preferably have some postgraduate experience in this field.

Both posts on scale for Research and Analogous Staff £3,410 to £4,892 per annum plus £450 per annum London Allowance. Appointments initially for three years from February 1, 1979, or as soon as possible thereafter. Further details from the Secretary, Institute of Archaeology, 31-34 Gordon Square, London WC1H 0PY, telephone 01-387 6052. Closing date for applications January 5, 1979. 8829(A)

UNIVERSITY OF ASTON IN BIRMINGHAM
DEPARTMENT OF MATHEMATICS
LECTURESHIP

Applications are invited for appointment as a lecturer in the Department of Mathematics. In addition to the usual teaching and examining responsibilities of this post, the appointee will be expected to participate in the research programme and administration of the Earth Satellite Research Unit. This Unit is funded by S.R.C. and operates two Hewitt cameras, one installed near Birmingham and the other to be sited in Australia.

Research experience in classical mechanisms and computing or in other relevant areas is required.

Commencing salary will be within the range £3,883 to £5,842 per annum according to age and qualifications) on a scale rising by annual increments to £7,754 per annum (currently under review).

Application forms and further particulars may be obtained from the Staff Officer (Ref. 322/6) University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET (Tel. 021-359 3611 Ext. 201) to whom applications should be forwarded not later than January 1, 1979. 8796(A)

BIOLOGY TEACHING OVERSEAS

RESEARCH–TEACHING positions available beginning Fall 1979 in such specialties as Ecology, Plant Physiology, Developmental Biology, Invertebrate Zoology. Ph.D. required, rank and salary depend on experience and qualifications. Usual contract is for 3 years with RT travel and other fringe benefits.

Curriculum vitae and letters of recommendation should be airmailed to: Dr Samir Deeb, Biology Department, American University of Beirut, Beirut, Lebanon.

Application review will begin March 1, 1979. 8842(A)

THE BRITISH COUNCIL

invites applications for the post of:

Lecturer in Plant Genetics
(Sri Lanka)

UNIVERSITY OF SRI LANKA, JAFFNA CAMPUS,

to plan and conduct undergraduate and advanced courses in Genetics and to guide postgraduate research. Candidates should hold a Ph.D., preferably in Plant Genetics or related field and have 2–3 years' teaching experience.
Salary: £5,681 to £7,707.

Benefits: Personal allowance, free furnished accommodation and other benefits. 2-year contract. Return fares are paid. Local contracts are guaranteed by the British Council.
Please write briefly stating qualifications and length of appropriate experience, quoting reference 78 PU 102 and title of post, for further details and application form to:

The British Council (Appointments)

65 Davies Street, London W1Y 2AA

8840(A)

UNIVERSITY COLLEGE GALWAY

DEPARTMENT OF MICROBIOLOGY

RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant commencing on January 1, 1979. This post, funded by the Medical Research Council of Ireland, will involve an investigation of mutagenesis in *E. coli.*

Applicants should hold a Degree in microbiology and should write immediately to:

Dr E. Farrell, Department of Microbiology,
University College Galway, Ireland

8860(A)

UNIVERSITY OF STRATHCLYDE

Applications are invited for a

POSTDOCTORAL RESEARCH FELLOW
or a
GRADUATE RESEARCH ASSISTANT

in Organic Chemistry in the Department of Pure and Applied Chemistry

The work will involve an investigation of chemotherapeutic agents based on studies of the biosynthesis of dihydrofolate. The appointee will have the opportunity to work in the areas of synthetic organic chemistry and enzyme chemistry and to collaborate with scientists in a major pharmaceutical company. The Graduate Research Assistant may be eligible to pursue research leading to a higher degree.

Salary scales on the national salary structure for research and analogous staff: Postdoctoral Research Fellow, Range 1A, commencing salary within the scale £3,883 to £4,882; Graduate Research Assistant, Range 1B, commencing salary within the scale £3,384 to £4,382. Superannuation benefit.

The appointment will date from January 1, 1979, or such other date as may be arranged and will be tenable for up to a period of three years.

Applications with curriculum vitae and names and addresses of two referees (quoting R47/78) should be sent as soon as possible to Professor H. C. S. Wood, Department of Pure and Applied Chemistry, University of Strathclyde, Thomas Graham Building, 295 Cathedral Street, Glasgow G1 1XL, from whom further particulars may be **obtained.** 8859(A)

THE LONDON HOSPITAL MEDICAL COLLEGE
(University of London)

SENIOR LECTURER/LECTURER IN MEDICAL PHYSICS
(Physiological/Clinical Measurement)

Applications are invited for the above newly established post, preferably at Senior Lecturer level. An honours degree in physics (or related subject), together with a higher degree is required, together with substantial knowledge and experience of electronics, preferably in the medical field. The duties will involve:

(i) Participation in the Research and Development work of Pre-Clinical and Clinical College Departments, including work on equipment associated with patient care;
(ii) Initiation of basic research;
(iii) Undergraduate and Postgraduate teaching in association with other Departments where required;
(iv) Liaison with the Physics Departments of the London Hospital.

Salary according to qualifications and experience in the range: Senior Lecturer, £7,506 to £9,263 plus £450 London Allowance p.a.; Lecturer, £4,382 to £7,754 plus £450 London Allowance p.a., together with superannuation under U.S.S. or N.H.S.

Further information available from Professor M. Braden, tel: 01-247 0644, extn 80. Applications, giving full details of qualifications and experience, together with the names of two referees, should be sent to The Secretary, The London Hospital Medical College, Turner Street, London E1 2AD, within **21 days.** 8861(A)

KINGSTON POLYTECHNIC
SCHOOL OF CHEMICAL AND PHYSICAL SCIENCES
SENIOR TECHNICIAN

To be responsible for a Life Science laboratory, used for undergraduate teaching, research and project work. Duties will include microbiology, plant studies and tissue culture work, plus experimental development and investigational work. An important job requiring someone with initiative and enthusiasm. Further details on application.

T3/4 grade £4,017 to £4,917 inclusive.

Application forms from Assistant Registrar (Personnel), Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. 01-549 1366.
8825(A)

UNIVERSITY COLLEGE CARDIFF

Applications are invited for the post of:

LECTURER

in the DEPARTMENT OF BIOCHEMISTRY.

Salary range: £3,883 to £7,754. Duties to commence as soon as possible.

Applications (2 copies), together with the names and addresses of two referees, should be forwarded to the Vice-Principal (Administration) and Registrar, University College, P.O. Box 78, Cardiff CF1 1XL, from whom further particulars may be obtained. Closing January 8, 1979. Please quote reference 1660.
8817(A)

CONGRESS

To mark its Centennial in 1980, The Graduate School of Arts and Sciences of Columbia University in the City of New York will convoke an International Congress meeting on

THE LANGUAGES OF KNOWLEDGE AND OF INQUIRY

concerned with the means whereby the various sciences, social sciences, and humanities pursue their inquiries and conceptualize and transmit their results.

University of California
Davis, Ca. 95616 U.S.A.

Monday, August 27: Physiology of gamete activation and interaction. Chairs: R. A. Leopold, USDA, Fargo, N. Dakota; V. D. Vacquier, University of California, San Diego.

Tuesday, August 28: Gonad-produced hormones. Chairs: A. Schuetz, Johns Hopkins University, Baltimore, Md.; K. G. Davey, York University, Ontario, Canada.

Wednesday, August 29: (informal meetings/workshops).

Thursday, August 30: Environmental synchronisation of reproduction. Chairs: J. Pearse, University of California, Santa Cruz; R. M. Woollacott, Harvard University, Cambridge, Mass.

Friday, August 31: Artificial manipulation of reproduction. Chairs: D. Morse, University of California, Santa Barbara; L. L. Sower, USDA, Forest Service, Corvallis, Oregon.

Symposiums will be held in the mornings, and afternoons will be devoted to contributed papers.

LECTURES

1st FEBS LECTURE TOUR

A new Lectureship Programme has been started by the Advanced Courses Committee of the Federation of European Biochemical Societies. The 1st FEBS Lecture Tour will take place in 1979.

GARY FELSENFELD

(Bethesda, Md)

will lecture on

"Nucleosome Architecture and Chromatin Function"

as follows:

February 1,	London (King's College Department of Biophysics)
February 1,	Cambridge (M.R.C. Laboratory of Molecular Biology)
February 5,	Orléans (Centre de Biophysique Moléculaire)
February 6,	Paris (Institut de Recherche en Biologie Moléculaire)
February 8,	Munich (Institut für Physiologische Chemie, Physikalische Biochemie, und Zellbiologie)
February 9,	Heidelberg (European Molecular Biology Laboratory)
February 12,	Strasbourg (Laboratoire de Génètique Moléculaire des Eucaryotes)
February 14,	Barcelona (Depto. de Quimica Macromolecular)

ASSISTANTSHIPS

BRIGHTON POLYTECHNIC
Faculty of Natural and Life Sciences
DEPARTMENT OF PHARMACY
RESEARCH ASSISTANTSHIP

Applications are invited from honours graduates in pharmacy, biochemistry or related disciplines, to pursue research in one of the following areas:—

1. The interaction of drugs with mucus;
2. The effects of biopolymers on drug absorption;
3. The release of drugs from polymeric systems.

Salary scale: £2,613 by £87 (2) to £2,787.

Details of post and application form from Administrative Officer, Faculty of Natural and Life Sciences, Brighton Polytechnic, Moulsecoomb, BRIGHTON BN2 4GJ, to whom completed forms should be returned by January 3, 1979
8849(P)

IMPERIAL COLLEGE
DEPARTMENT OF ZOOLOGY

Applications are invited for a postdoctoral Research Assistantship tenable at the College Field Station for work for three years on a Medical Research Council sponsored project on the sexual development of malarial parasites. The successful applicant will be expected to develop new methods for the culture and purification of the parasite, and to study the biochemistry/physiology of the parasite plasmalemma. Experience in the fields of cell fractionation of membrane chemistry would be an advantage.

Salary in the range £3,883 to £4,631 on the Research and Analogous Staff scale, plus U.S.S.

Applications with the names of two referees in writing by December 15, to Dr R. E. Sinden, Imperial College Field Station, Ashurst Lodge, Ascot, **Berks.**
8604(P)

ASSOCIATESHIP

HERIOT-WATT UNIVERSITY
DEPARTMENT OF PHYSICS
POCTDOCTORAL RESEARCH ASSOCIATESHIP IN SOLID STATE THEORY

Applications are invited for an S.R.C. Postdoctoral Research Associateship, for studies of Anderson localisation and other topics in the theory of disordered solids, in association with Dr D. Weaire. The starting date should be no later than October 1, 1979.

Informal enquiries can be addressed to Dr Weaire.

Initial salary will be in the range £3,883 to £4,382 p.a. (under review) of Range 1A.

Application forms are obtainable from the Staff Officer, Heriot-Watt University, Chambers Street, Edinburgh EH1 1HX. Ref. No. 22/78.
8841(O)

FELLOWSHIPS

UNIVERSITY OF NOTTINGHAM
FACULTY OF AGRICULTURAL SCIENCE
Readvertisement
RESEARCH FELLOWSHIPS (PHYSICS/ENGINEERING)

Two fellowships are available for projects supported by the A.R.C. The first is concerned with the physics and economics of very low cost solar energy collectors for use in crop drying and the successful candidate will work with Dr J. A. Clark and Mr B. Wilton. The second project, supervised by Professor J. L. Monteith, will examine the feasibility of assessing the growth rate of crops from the spectral composition of reflected radiation, including measurements from the air.

Both appointments are for three years. Candidates should preferably have a Ph.D. or equivalent experience in an appropriate branch of physics, engineering, or environmental science (salary scale commencing £4,382 per annum at age 26). Applications will also be considered from newly qualified graduates with a good honours degree (salary scale commencing at £3,384 per annum).

Applications with the names of two referees should be submitted to and further details may be obtained from The Secretary, University of Nottingham School of Agriculture, Sutton Bonington, Nr. Loughborough.
8790(E)

The Wellcome Trust

Wellcome Research Fellowships in Veterinary Medicine

Applications are invited for research fellowships in Veterinary Medicine from Veterinary graduates in British Universities who have already had at least three years' post-graduate research experience.

The Fellowships are tenable for up to three years and may be held in any University Department or Research Institute in the United Kingdom concerned with research. Applications must be sponsored by the Head of a Department who is an expert in the field of study chosen by the candidate. Age limit is 32 years.

Salary is according to age: £4,382 per annum at the age of 26, rising to £5,842 per annum at the age of 32. In addition £500 per annum is given to the Head of the Department as a contribution towards the research expenses of the Fellow. In cases where veterinary graduates propose to submit their work for a PhD degree a lower scale will apply.

Wellcome Veterinary Research Training Scholarships

Applications are invited from Veterinary graduates of British Universities (or those who expect to graduate in 1979) for Research Training Scholarships in the United Kingdom.

These scholarships are for training in research techniques and may be held in any University Department or Research Institute in the United Kingdom in which work can be carried out for a PhD. Applications must be sponsored by an expert in the field of study chosen by the candidate.

The Scholarships are tenable for three years subject to satisfactory annual reports, and carry a stipend of £2,752 per annum. In addition the Trustees will pay for all approved College Fees and £500 per annum is given to the Head of the Department as a contribution towards the research expenses of the scholar.

Application forms are available from: Grants Section, The Wellcome Trust, 1 Park Square West, London NW1 4LJ. Tel: 01-486 4902.

Closing date for applications is 14th February, 1979.

8828(E)

Cancer Research Campaign

Post-Doctoral Research Fellowship in Biochemistry

A postdoctoral research fellowship is now available for work at the Microbiological Research Establishment on coupling biologically active proteins to polysaccharides to improve performance in antitumour therapy and for application in diagnostic enzymology. Experience in protein : polysaccharide interaction and enzymology is desirable. The post is tenable for up to three years with a starting salary in the range £4,101 to £4,579.

Research Assistant

An assistant with good academic qualifications is required to support the work of a postdoctoral research scientist on the above project. The post is tenable for up to three years with a starting salary in the range £2,319 to £2,633.

Applications, including a full curriculum vitae and two academic referees should be sent to The Director, Microbiological Research Establishment, Porton, Salisbury, Wiltshire.

Closing date for applications is January 4, 1979.

8803(E)

THE ROYAL SOCIETY
LOCKE RESEARCH FELLOWSHIP
ROSENHEIM RESEARCH FELLOWSHIP

Applications are invited by the Council of the Royal Society for:

(a) A Locke Research Fellowship for research in experimental physiology and pharmacology;

(b) The Rosenheim Research Fellowship established under the will of the late Mrs M. C. Rosenheim for research on the biochemistry of plants and the simpler forms of animal life. Preference will be given to candidates wishing to study the biochemistry of higher plants.

Both appointments are tenable in any appropriate university department or research institution approved by the Council of the Royal Society (the Rosenheim Research Fellowship is restricted to places in Great Britain). Candidates should supply the usual personal details and two referees. Testimonials will not be considered. The subject of the proposed research and where it will be done, together with the name of the head of department, whose consent should first be obtained, must be stated.

The appointments, which will be subject to the Society's general regulations governing research appointments, will be tenable for three years in the first instance from October 1, 1979, and may be renewable for a further two years, such renewal being considered at the end of the second year of tenure. Applicants should preferably be under 33 for the Locke Research Fellowship and under 26 for the Rosenheim Research Fellowship on October 1, 1979.

Stipend scales are as follows (the point of entry will be determined by Council), and superannuation benefits are provided: Locke Research Fellowship (Category C): £6,153 by £240 to £7,113 by £243 to £7,356 per annum; Rosenheim Research Fellowship (Category D): £4,461 by £249 to £5,706 per annum.

Applications should be made on forms to be obtained (stating name of Fellowship) from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG, and should be received not later than February 28, 1979.

8848(E)

FELLOWSHIPS continued

UNIVERSITY OF SUSSEX
SENIOR AND JUNIOR RESEARCH FELLOWSHIPS
IN THEORETICAL ASTRONOMY

Applications are invited for S R C.-supported posts of Research Fellow in Theoretical Astronomy, for a period of one or two years, with possible extension to a third. There is one Senior Research Fellowship, with a stipend equivalent to the Reader scale (£7,506 to £9,263 per annum, under review) The junior posts are based on the Research Fellow 1A scale (£3,883 to £6,555 per annum, under review) All posts carry U.S S. benefits Appointments will normally commence on October 1, 1979.

Candidates should propose an independent research programme Further information can be obtained from Professor L Mestel, Astronomy Centre, Physics Building, University of Sussex, Falmer, Brighton BN1 9QH, U.K Applications should arrive by **January 31, 1979.** Applicants should ask up to three referees to send confidential reports, to reach the Astronomy Centre by the same date.

8801(E)

CHRISTIE HOSPITAL & HOLT RADIUM INSTITUTE

Withington, Manchester M20 9BX

PATERSON LABORATORIES

FELLOWSHIP IN CELL BIOLOGY

Fellowship available at postdoctoral level for studies on epithelial proliferation and differentiation control in collaboration with Dr C S Potten Some experience in the cellular pathology of replacing tissues would be an advantage The fellowship (£4,631 per annum) would be tenable from early 1979

Letters of application together with curriculum vitae should be sent to the Director, Professor L G Lajtha, as soon as possible Ref· 78/72

8794(E)

JOHN INNES INSTITUTE POSTDOCTORAL FELLOWSHIP

The use of protoplasts for the interspecific and intergeneric transfer of chromosome fragments.

Work with animal cells has shown that heterokaryons formed by the fusion of somatic cells can be exploited in such a way as to lead to the transfer of chomosome fragments from a donor to a recipient cell We now seek a postdoctoral fellow to explore the possibility of similarly exploiting heterokaryons of plant cells There is considerable expertise in the technology of protoplast production and manipulation within the John Innes Institute where protoplasts are used as vehicles for studying virus infection and multiplication The person appointed will work in collaboration with this group.

Candidates who have a background in molecular biology, genetics or related fields are invited to apply for this fellowship which is for a period of three years and will be funded by the John Innes Charity Salary will be in the scale £4,101 to £5,065 per annum according to experience Superannuation.

Further details are available from Professor R W. Horne, John Innes Institute, Colney Lane, Norwich NR4 7UH

Applications with curriculum vitae, full details and the names of two referees should be sent to the Secretary, John Innes Institute, Colney Lane, Norwich NR4 7UH by February 3, 1979.

8823(E)

THE OPEN UNIVERSITY

Discipline of Earth Sciences Postdoctoral Research Fellow

Applications are invited for a three year postdoctoral research fellowship supported by NERC The PDRA will investigate metamorphic and geochemical changes associated with major shear belts in the Archaean craton of South India The study will be part of a collaborative project with the National Geophysical Research Institute and Geological Survey of India. Previous analytical and field experience in complex Precambrian terrains would be an advantage.

Salary in the range £3,883 to £6,555 p a. with superannuation benefits Appointment is from as soon as possible

Application forms and further particulars are available, by postcard request please, from The Recruitment Office (JD3722/2), The Open University, P O Box 75, Walton Hall, Milton Keynes, MK7 6AL or telephone Milton Keynes 63868 24 hour answering service. Closing date for applications. 20th December, 1978

8822(E)

UNIVERSITY OF SURREY RESEARCH FELLOWSHIP
EMBRITTLEMENT BY LIQUID METALS

There is a vacancy in the field of high temperature surface reactions for work concerned with the embrittlement of steels by liquid zinc The structure, composition and the physical nature of the reacted specimens will be examined using a wide range of analytical techniques including metallography, Electron-probe, E S C A etc.

The post will be suitable for either a postdoctoral Fellow wishing to gain further experience in the field of high temperature surface reactions or a graduate experienced in the field of solid metal-liquid metal surface reactions

Preference will be given to candidates with a lively interest in practical work and an imaginative approach to interpretation. The appointment will be for two years Starting date is visualised as January 1, 1979 or as soon as possible thereafter The salary will be on an appropriate point on a scale range £3,883 to £5,367 per annum

Applications in the form of a curriculum vitae, including the names and addresses of two referees should be sent to Dr J Mackowiak, Department of Metallurgy and Materials Technology, University of Surrey, Guildford, Surrey GU2 5XH

8792(E)

UNIVERSITY OF GLASGOW
DEPARTMENT OF CHEMISTRY
M.R.C POSTDOCTORAL FELLOWSHIP

The above position is available from March 1, 1979, for the determination of the structure of Chloramphenicol acetyl transferase at atomic resolution. Experience in protein crystallography is essential Starting salary will be within Range 1A of the salary scale for Research and Analogous Staff, £3,883 to £4,382, depending on age and experience

Further particulars are available from Dr I D A Swan, Department of Chemistry, University of Glasgow, Glasgow G12 8QQ, to whom applications, together with a curriculum vitae and the names of two referees, should be addressed

In reply please quote Ref No 4325M.

8812(E)

SCHOLARSHIPS

QUEEN ELIZABETH COLLEGE
Kensington
(University of London)
POSTGRADUATE RESEARCH SCHOLARSHIPS
October 1979

Applications are invited for postgraduate research scholarships in science tenable at Queen Elizabeth College Candidates should, by the date of the appointment, have obtained a first class or an upper second class honours degree from a British University, or hold an equivalent qualification and they should have a clear idea of the topic on which they wish to undertake research Appointment will be offered following competitive interview and will be in one of the College departments or units, i e :-

Biochemistry
Biology
Chemistry
Food Science and Nutrition
(including Management Studies)
Mathematics
Microbiology
Physics
Physiology
Computer Unit
Isotope Unit

The maximum value of the basic maintenance award is £1,990 p a (1978/79 rates, currently under review), plus approved fees Certain expenses and allowances are payable in addition where applicable Holders may be asked to undertake demonstrating for which additional payment will be made.

Queen Elizabeth College is a science-based institution with approximately equal numbers of men and women students. Out of a student body of some 1,050, 250 are postgraduates As the departments are all on the same pleasant four-acre site on Campden Hill in Kensington, interdisciplinary contacts are readily established Public transport and parks are nearby Some accommodation is available in College-owned houses

Further particulars and application forms are obtainable from the Academic Registrar, Queen Elizabeth College, Campden Hill Road, London W8 7AH, to whom application forms should be returned by April 1 1979

FEBS ADVANCED COURSES

No. 58, "Biomolecular Electron Microscopy"
Ulm, FRG,
29 March—7 April 1979

The Course, organized by A K. Kleinschmidt, is intended to offer information on selected methods of biomolecular structure studies, and laboratory instruction in electron-microscopic methods of macromolecular analysis, to 40 qualified applicants Specialised fields, e.g. electron microscopy of nucleic acids, membrane structure, nucleoprotein particles, immunocytochemistry, lipoproteins and proteoglycans, and autoradiographic procedures and image analysis methods will be included to participants' choice in laboratory practical sessions. Course fee, including accommodation and food; approx DM400 — Applications (b **January** 1979) and info. Dr A K. Kleinschmidt, University of Ulm, Department of Microbiology, Postfach 4066, 7900 Ulm, FRG.

No. 60. "Gene Structure and Formation of RNA of Viruses and Animal Cells"
Israel, 15—21 May 1979

A workshop organized by Y. Aloni and co-sponsored by EMBO. Fee: $280.— Info: Mr Y. Berman, Congress Section, Weizmann Institute of Science, Rehovot, Israel.

No. 62. "Genome Organization and Expression in Higher Plants"
Edinburgh, Scotland,
11–21 July 1979

A course for up to 125 participants Accommodation including ful board, £130 approx Applications (**by 14 February 1979**) and info: Dr C Leaver, Dept of Botany, The King's Buildings, Mayfield Road, Edinburgh, EH9 3JH, Scotland

No. 56. "Membrane Proteins"
Berne, Switzerland,
10–22 September 1979

The course, co-sponsored by the Swiss Committee for Molecular Biology and organized by P Zahler and A Azzi, will consist of 1 week each of lectures and experimental work, and discussions The course will concentrate on specific problems of membrane proteins (solubilization, fractionation, isolation, characterization, reconstitution) Places will be restricted to 80–100 for the lectures and to 40 advanced participants for the experimental part Fees (including registration, accommodation and food)· Sw Fr.700.—for the full course or Sw Fr 340 —for the lecture course only Applications should be addressed **before 1 April, 1979** to: Professor P Zahler, Institut für Biochemie, Universität Bern, Freiestrasse 3, CH-3012 Bern, Switzerland.

No. 57. "Genetic Engineering"
Zagreb, Yugoslavia,
8–24 October 1979

Info: Dr V. Škarić, Institut "Ruđer Bošković", Post. pret 1016, 41001 Zagreb, Yugoslavia.

Cloning Reagents from BRL

Terminal Transferase - T4 DNA Ligase

Regardless of how you construct your plasmid chimaera, BRL terminal transferase and DNA ligase are guaranteed to get the job done.

BRL's T4 DNA ligase has excellent activity for joining blunt (base paired) ends of DNA—a rigorous challenge of ligation efficiency. For homopolymer "tailing" of duplex DNA, you can expect terminal transferase from BRL to add at least 50 residues dAMP or 200 residues dTMP per strand within 30 minutes (λ DNA ends).

BRL Terminal Transferase and T4 DNA Ligase: the reagents of choice for cloners the world over.

Microbiological Research Establishment

Microbial Products

Azurin
Minimum Quantity 100mg @ £280
Isolated from **Pseudomonas aeruginosa**
this product is pure (A_{625}/A_{280} = 0.58).
Supplied as a solution which is stable when
stored at −20°C.

Micrococcal Nuclease
Minimum Quantity 10^6 units @ £336
(5 × 10^6 units @ £1300; 10^7 units @ £2200)
Isolated from **Staphylococcus aureus**
(Foggi). Supplied as a lyophilised powder
with a minimum specific activity of 8000 U/mg
protein. Stable at +4°C.

Staphylococcal Immunoadsorbent
Minimum Quantity 2.5 litres @ £200
Heat killed, formaldehyde treated cells of
Staphylococcus aureus (Cowan Str. 1)
washed three times with buffer. Supplied as
a 10% wet weight/volume suspension in
150 mM NaCl, 40 mM potassium phosphate,
pH 7.2 containing 0.02% NaN_3 Stable
at +4°C.

Superoxide dismutase
Minimum Quantity 100mg @ £280
Isolated from **Bacillus stearothermophilus**
and purified to homogeneity with a specific
activity of 2900 U/mg protein. Supplied as a
solution in 20 mM potassium phosphate,
50% glycerol pH 6.8. Stable at −20°C or for
one year at +4°C.

Transfer RNA
Minimum Quantity 2 grams @ £210
Isolated from **Escherichia coli** K12 CA265
as mixed species tRNA containing about 50%
chargeable tRNA as judged by
aminoacylation. Supplied as a suspension in
70% ethanol. Stable at −20°C.

The listed products are offered at the quoted sterling prices, which remain firm until 1 April 1979 subject to availability. Prices include packing and delivery on UK orders, which are subject to VAT at ruling rates. Overseas orders are subject to transport charges at cost. For listed items please send your official order and delivery instructions to the:

Microbial Products Section,
Microbiological Research Establishment,
Porton, Salisbury, SP4 0JG, Wiltshire, UK.

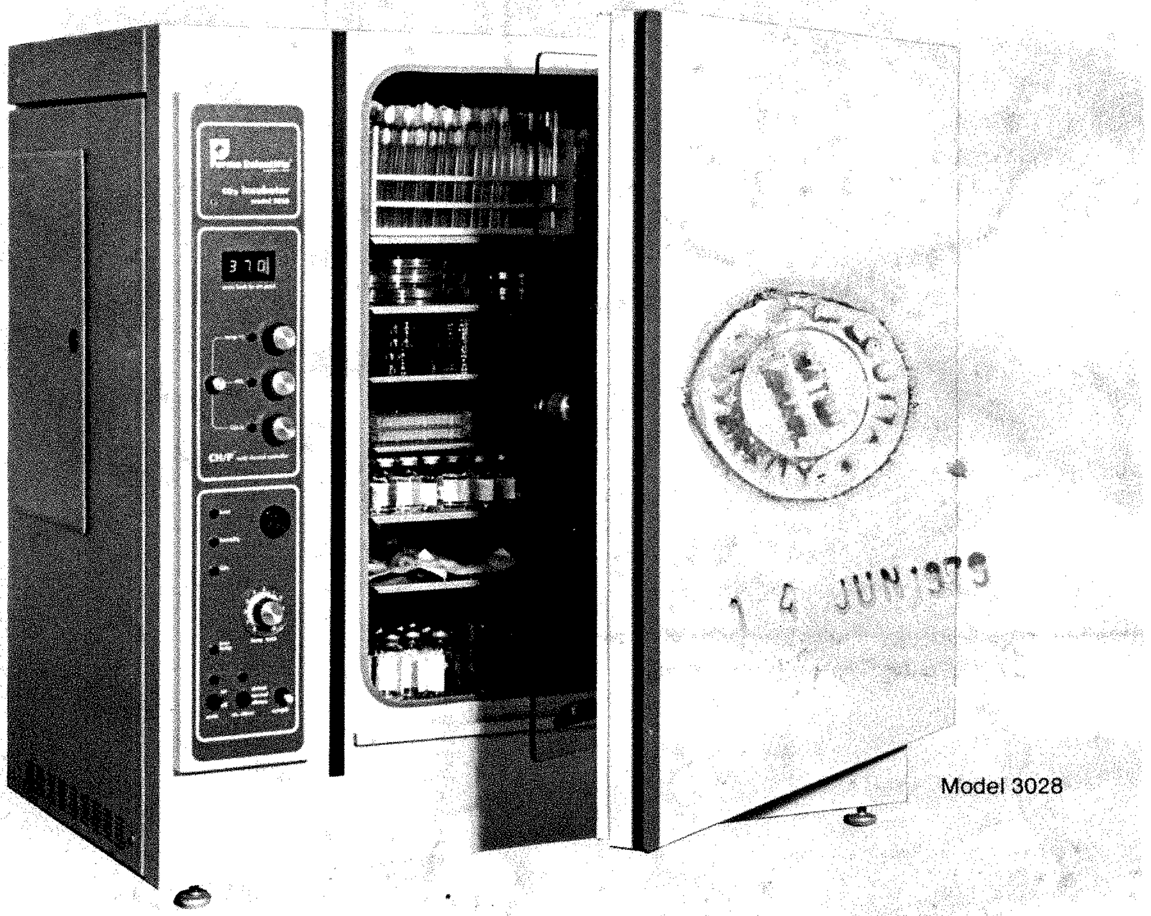
If it isn't Forma, it isn't CH/P.™



Model 3028

14 JUN 1979

And if it isn't CH/P, it isn't the finest incubator controller in the world.

Forma's CH/P System is a miniature computer that senses, calculates, and remembers. A multi-channel controller that gives you direct digital setpoint and digital display of temperature, relative humidity, and CO_2. A technical revolution that goes a step beyond solid-state electronics.

Forma's new CO_2 sensor is the most accurate available because we built it ourselves. CH/P totally eliminates obsolete hot wire sensors prone to corrosion in high humidity.

CH/P assures precise linear control of CO_2 setpoints to within .1% over the full 0-20% range. And a *unique* CO_2 Deviation Alarm protects against CO_2 drift from your setpoint.

The CH/P System relative humidity controller eliminates humidity sensors and wet/dry bulb probes. CH/P computes and controls two independent heat sources to balance your RH% against your temperature setpoint. The result is a maintenance-free yet amazingly accurate RH% system designed specifically for CO_2 incubators.

The CH/P mini-computer also controls direct digital temperature setpoints in .1 °C increments with accurate control sensitivity to within .06 °C. And Forma's *unique* horizontal air flow assures remarkable top to bottom temperature uniformity throughout the cabinet.

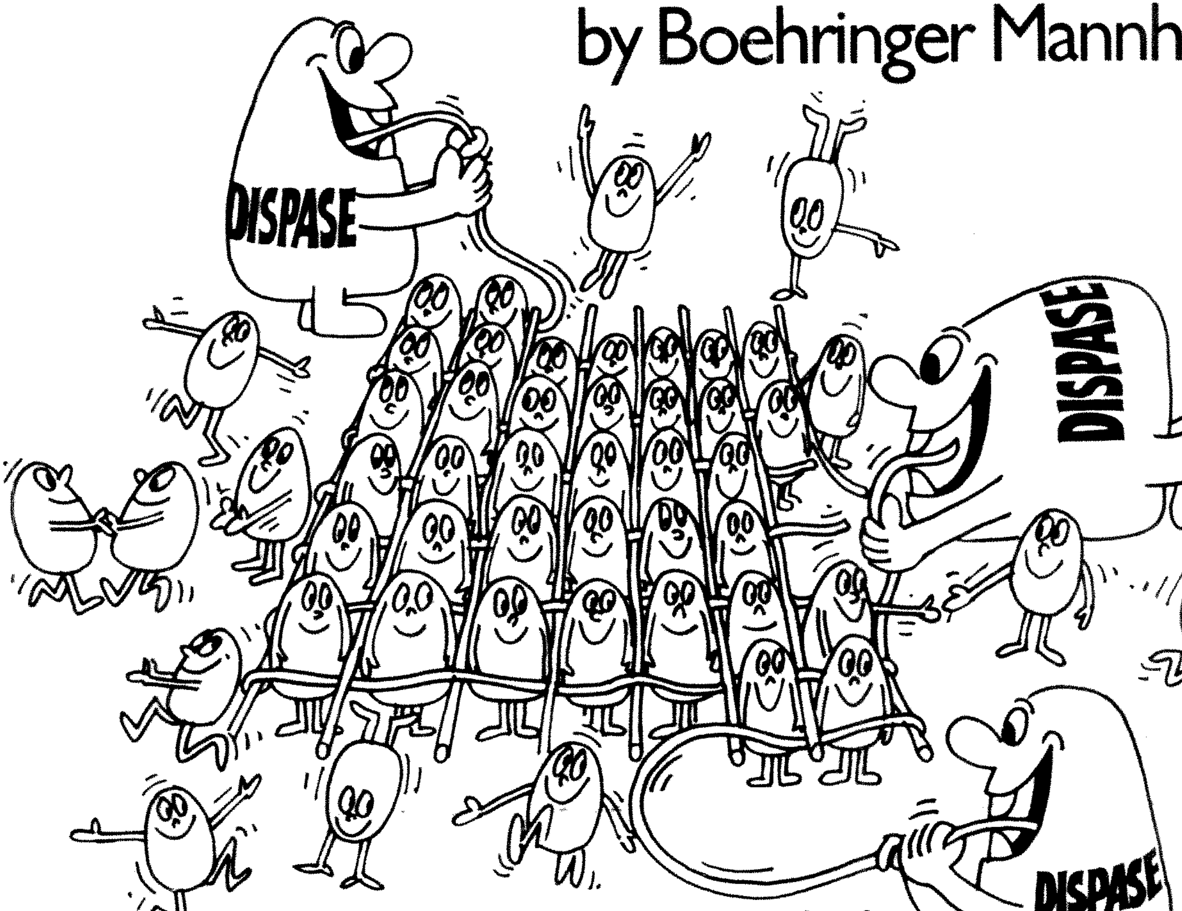
Capillary waves

The big liberator is here!

A revolution in tissue culture techniques by Boehringer Mannheim!



The neutral protease "Dispase" is the most favourable enzyme in tissue culture techniques for the enzymatic disintegration of tissues into single cells or to keep cells in suspension culture.

The advantages over trypsin are:

- * no damage of cell membranes
- * no inhibition of cell growth
- * tissue disintegration in presence of a complete nutrient medium even with serum
- * increase of the yield of living cells
- * no loss in enzyme activity under tissue culture conditions
- * no contamination by viruses or mycoplasms possible

Commercially available:
Dispase, Grade I, Cat. No. 241750
Dispase, Grade II, Cat. No. 165859
Dispase/Collagenase mixture, Cat. No. 269638

EMBO

WORKSHOPS PROVISIONAL PROGRAMME 1979

Subject	Organiser and Address for Further Information		Date Place Number of Participants
Genetic Recombination	Professor N. Symonds	Biology Building The University of Sussex Falmer Brighton BN1 9QG ENGLAND	25 — 30 June Nethybridge 60
Chromatin	Dr. G. Milanesi	Laboratorio di Genetica Biochimica ed Evoluzionistica Via S. Epifanio, 14 27100 Pavia ITALY	23 — 26 March Courmayeur 50
The Molecular Biology of the Gene	Professor M. Birnstiel	Institut für Molekularbiologie II Winterthurerstr. 266A 8057 Zürich SWITZERLAND	18 — 22 March Davos 50
Muscle Cell Culture in the Study of Gene Expression during Differentiation	Dr. M. Shani	Department of Cell Biology Weizmann Institute of Science Rehovot ISRAEL	October Rehovot 75
Chloroplast Membrane Polypeptides	Professor D. von Wettstein	Department of Physiology Carlsberg Laboratory Gl. Carlsbergvej 10 2500 Copenhagen Valby DENMARK	11 — 16 June Copenhagen 30
The Nerve Growth Factor and other Specific Growth Factors	Professor R. Levi-Montalcini	Laboratorio di Biologia Cellulare Via G. Romagnosi 18/A 00196 Rome ITALY	early in October Rome 40-50
Comparative Study and Recent Knowledge on Quaternary Structure and Active Sites of Oxygen Carriers and Related Proteins	Professor J. Lamy	Laboratoire de Biochimie Faculté de Médecine 2, bis Bd. Tonnellé 37032 Tours Cédex FRANCE	20 — 24 August Tours 50
Concepts of Chemical Recognition in Biology	Dr. F. Chapeville	Laboratoire de Biochimie du Développement, Institut de Recherche en Biologie Moléculaire du CNRS 2, Place Jussieu-Tour 43 75221 Paris Cédex 05 FRANCE	17 — 21 July Thiverval-Grignon 70
X-ray and Neutron Small Angle Scattering of Biological Structures	Professor H. Stuhrmann	European Molecular Biology Laboratory Notkestieg 1 2 Hamburg 52 FEDERAL REPUBLIC OF GERMANY	24 — 28 September Hamburg 40-60
Polypeptide Neurotoxins: Structure and Function	Professor M. Lazdunski	Centre de Biochimie Faculté SPCNI Université de Nice Parc Valrose 06034 Nice FRANCE	24 — 27 July Nice 50-80
EMBO-FEBS Workshop on Gene Structure and Formation of RNA of Viruses and Animal Cells	Professor Y. Aloni	Public Affairs Office Weizmann Institue of Science Rehovot ISRAEL	15 — 21 May Rehovot 75
Cell Lineage, Stem Cells and Determination	Professor N. Le Douarin	Institut d'Embryologie CNRS 49bis, av. de la Belle Gabrielle 94130 Nogent-sur-Marne FRANCE	20 — 24 May Onzain 40
Molecular and Cellular Aspects of Obesity	Professor G. Ailhaud	Centre de Biochimie Faculté des Sciences Parc Valrose 06034 Nice FRANCE	27 — 29 August Nice 50-70
Erythropoieses and Differentiation in Friend Leukemia Cells	Professor G. B. Rossi	Laboratorio di Malattie Batteriche e Virali Istituto Superiore di Sanità 299 Viale Regina Elena 00161 Rome ITALY	September/November Urbino 60
Control of Replication and Partitioning of Bacterial Chromosomes and Plasmids	Professor R. Pritchard	Department of Genetics University of Leicester University Road Leicester LE1 7RH ENGLAND	September Leicester 45
H-2 Antigens: Genetic Control, Expression and Function of Normal, Tumour and Virally Infected Cells	Professor H. Festenstein	The London Hospital Medical College University of London Turner Street London E1 2AD ENGLAND	29 April — 3 May London 25

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**,1 (1975) and **264**, v, 11 Nov. (1976).

Sephacryl®

the different medium for gel filtration

- Faster separations: Sephacryl has speed and resolution to spare; separates proteins 5–10 times faster than conventional media.
- Faster packing: Sephacryl is pre-swollen, ready-to-use and packs fast.

Use Sephacryl S-300 Superfine for separations up to an exclusion limit of 1.5 million for globular proteins; ideal for serum proteins. Use Sephacryl S-200 Superfine up to an exclusion limit of 250,000 for globular proteins.

When you use Sephacryl, the difference is clear. Find out more about Sephacryl from your usual supplier of Sephadex®, Sepharose® and other separation media.

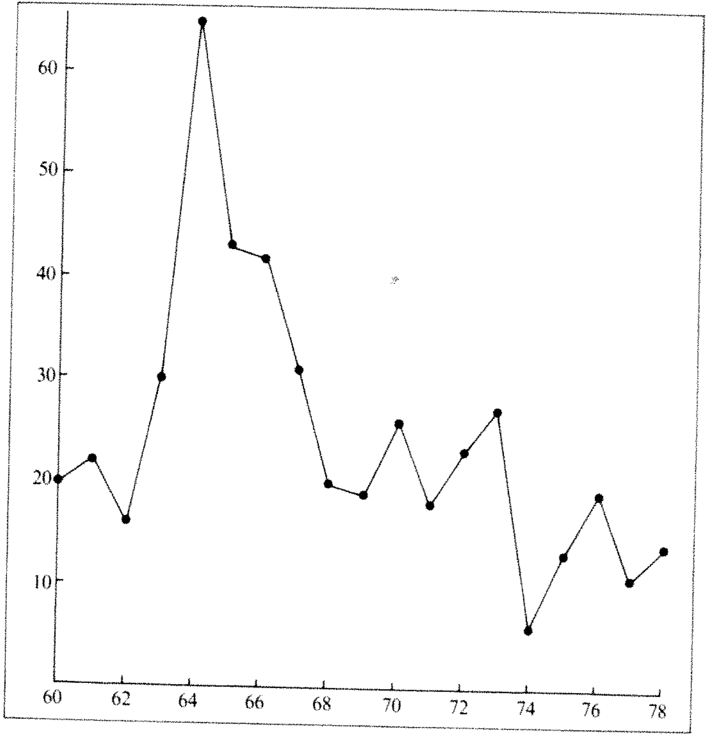
No end in sight to jobs gloom

Four years ago (Vol. 253, p. 79) we looked at the fluctuations in job opportunities in British universities since 1960. Now is a suitable time to bring the record up to date. The graph shows in a schematic way numbers of tenured posts available up until the end of 1978.

The technique used is the same as that employed in 1975. The classified advertisements in *Nature* for two weeks, in May and November, of each year were examined. Posts at or above the level of lecturer at a British university scored one. Temporary posts scored half. The figures for May and November were added together. Various objections can be raised; that not all jobs will be advertised in *Nature;* that the method of measurement, though consistent, is crude; that many universities have research-council establishments attached to them which perhaps should also be included; that there are large research-council and other establishments not attached to universities but which offer at least a semi-academic environment. Nonetheless, it is likely that the graph is a moderately good guide to the ups and downs of employment prospects for the academically inclined.



The enormous spike in the mid 1960s need not detain us long. This was the time when new universities were rapidly coming on stream and recruiting with immense enthusiasm. This cohort of new-university staff is now largely in its 30s and 40s and unlikely to retire for some time. In the late 1960s recruiting seemed to return to its old level but then in 1974 many university posts were 'frozen', owing to a major economic crisis.

What has happened since then? There has been no obvious rebound; it must be assumed that many of the frozen posts have never re-appeared. In fact the level of recruitment in the past four years looks unmistakably down on that of the early 1970s, for which the present low-level of retirements from universities must take part of the responsibility. Nor is there much comfort just over the horizon. The numbers of students choosing to do science at university is certainly not growing quickly enough to warrant major increases in staff; indeed in recent years numbers have often declined. And the demographic signs are unmistakably that young people of university age will be substantially less in number in ten years' time than they are now, so teaching opportunities are hardly likely to increase.

At present a large and growing number of post-doctoral research workers find themselves caught in the trap. Tenured posts are few and far between whilst short-term contract research merely delays the day of decision and offer no security. The recently formed Association of Researchers in Medical Sciences, intended to articulate the concern of medical researchers thus trapped, could easily have a counterpart in other branches of science.

No one simple solution will emerge to this very serious problem. The encouragement of early retirement is likely to increase, and will help, at least temporarily. Specific initiatives have helped in some particularly difficult circumstances. But in the long run the responsibility may lie as much as anywhere on those tenured university staff who take on new graduates to study for a Ph.D. In the flush of satisfaction at having found just the right person to solve the problem in hand, it is all too easy not to make discouraging noises at the same time about long-term job prospects. Research students should be told in no uncertain terms that a Ph.D. is no longer a guarantee of entry into the academic world and in some circumstances overqualifies for non-academic jobs and so could even be a liability. Any research supervisor who fails to make potential students think twice about the path on which they are entering is failing in one of his most important responsibilities. □

US extends recombinant DNA controls to private industry

A SERIES of moves was announced this week by Mr Joseph A. Califano, Jr, US Secretary of Health, Education and Welfare, designed to extend the guidelines currently covering federally-sponsored research involving the use of recombinant DNA techniques to all such research carried out in the private sector.

In particular, Mr Califano has directed the Food and Drug Administration to use its statutory authority to require that all recombinant DNA research submitted to satisfy regulatory requirements—for example in order to licence a new drug—comply with the guidelines that have been developed by the National Institutes of Health.

And as regards research in the private sector which would not be submitted to the FDA in this way, he has requested the Environmental Protection Agency to take all the action it can "to require that recombinant DNA research conducted by the private sector complies with the NIH guidelines."

Mr Califano also announced that he has approved final guidelines prepared by Dr Donald Fredrickson, director of NIH, that significantly revise the safety requirements for conducting recombinant DNA research.

As expected, the revised guidelines substantially broaden public representation on the Recombinant DNA Advisory Committee, which assists the NIH in administering the guidelines. It also increases public participation in the administration of the guidelines by local biosafety committees, as well as public access to information about recombinant DNA research.

Finally, since the revised guidelines require the director of NIH to determine that any proposed action under the guidelines "presents no significant risk to health or to the environment," Mr Califano has directed the NIH to formulate a balanced programme of risk-assessment experiments at NIH directly, or under NIH support.

"In my view, the more risk assessment experiments NIH carries out, the better we will be able to judge whether the guidelines—and actions taken under them—afford appropriate protection for health and the environment," he says in a memorandum to Dr Fredrickson and Dr Julius Richmond, Assistant Secretary for Health.

In a public statement announcing these various actions, Mr Califano says that the final version of the NIH guidelines based largely on proposed revisions published in July, relax in two major respects the guidelines that were placed in effect in 1976.

The first is that the revisions exempt altogether five categories of experiments, which the NIH has concluded present no health risk. This will exempt approximately one-third of the research now covered by guidelines.

The second relaxation is a general easing of restrictions on other permissible experiments. Almost all categories of research are assigned to physical containment and/or biological containment levels at least one step lower than in the 1976 guidelines.

"Since the likelihood of harm now appears more remote than was once anticipated, the scientific community has now concluded that this downgrading is appropriate," Mr Califano says.

A number of significant changes to the proposed revisions have been introduced to the ways in which the guidelines are administered, following a review carried out by a departmental committee chaired by Mr Peter Libassi, DHEW's general counsel.

In particular, whereas the 1976 guidelines had no specific requirements for public participation, it is now specified that 20% of the members of local institutional biosafety committees (IBCs) must represent the public, and have no connection to the institution.

It is also now required that the same proportion of the Recombinant DNA Advisory Committee be "persons knowledgeable about such matters as applicable law, standards of professional conduct and practice, public and occupational health, and environmental safety". And it is recommended that one member be a "non-doctoral" person from a laboratory staff.

To take in these extra interests, the membership of the committee is to be increased to 20, and the new members are expected to be announced by Mr Califano in the near future. Furthermore all federal agencies represented on the Federal Interagency Advisory Committee will have non-voting members on the RAC.

One result of demands for increased public participation is that all important records relevant to research carried out under the guidelines must be made public. In particular, the bulk of IBC records must be made available to the public, and problems, violations of the guidelines, illnesses and accidents must be reported to NIH.

Major actions under the guidelines—such as decisions to approve on a case-by-case basis experiments that are generally prohibited, to exempt additional categories of research from the guidelines, or to permit the insertion of genes into new types of bacteria—cannot be taken without the advice of the RAC, with public and federal agency comment on the proposals.

Califano: more risk assessment experiments

In addition, the Director of NIH cannot approve any proposed actions unless he determines "that they present no significant risk to health or the environment". This implies the need for some type of risk assessment.

In a statement accompanying the final version of the guidelines, Dr Fredrickson says that one reason for distinguishing between the hazards of different organisms on the basis of phylogenetic relatedness—a subject recently debated in Britain's Genetic Manipulation Advisory Group (GMAG)—is that the more closely related the species, the more likely that polypeptide hormones or related proteins would be pharmacologically active, particularly in the case of recombinant DNA integrating into the human genome.

"This matter lies in a crucial area of risk analysis and will undoubtedly continue to be a subject of both further debate and improved understanding in the coming months", Dr Fredrickson writes.

The final guidelines also include detailed presentation of the types of responsibility to be delegated to the local biosafety committees. Dr Fredrickson says that although this will place a burden on the human and financial resources of the institution, the responsibility is better delegated than retained at the federal level.

A new proposal will allow NIH to require prior approval of all recombinant DNA research if the institution fails to comply with the guidelines.

David Dickson

UK researchers claim rights over short-term contracts

At least two scientists believe universities and research councils are treating post-docs shabbily, writes **Joe Schwartz**

Two British scientists are turning to the courts and industrial tribunals to find redress over dismissal at the end of short-term research contracts. Dr Desmond Turner has brought a tribunal hearing against the University of Sussex; and Dr Amiram Ur is bringing another, continuing this week, against the MRC's Clinical Research Centre in Harrow.

Dr Turner, 39, was asked to leave the University of Sussex in June at the end of an MRC-funded project to isolate gastro-intestinal hormones involved in the regulation of insulin secretion. Dr Ur, 44, was also asked to leave, in his case after limited-term contracts totalling eight years' work with the MRC at Harrow.

Both have been productive scientists. Turner has published 15 papers relating to the hormonal regulation of insulin secretion over a period of 14 years on short-term contracts. Ur, a bioengineer, has numerous patents, most notably an impedance measuring device for monitoring blood coagulation and bacterial cell growth which is patented in 18 countries and is marketed in the UK under the names Biobridge and Bactbridge.

Turner and Ur have found themselves at the centre of a legal and political thicket. First, the legal status of short-term contract workers is not at all clear. Despite the fact that post-doctoral fellowships, for example, extend only for an agreed fixed term, there appear to be rights under the Employment Protection Act, 1975, to redundancy pay and claims over unfair dismissal at the end of the contract. But increasingly employers—universities and research councils—have been introducing a 'waiver clause' into the contracts which nominally eliminate those rights.

Turner says: "There is no justification for the use of special forms of contract that deprive employees of their normal rights under the law. . . . We need to bring to public notice the shabby way in which institutions are treating temporary appointments".

On the one hand it would seem sensible that the granting institutions should be free to allocate money according to their own perception of scientific merit without fear of redress. On the other, it would also seem fair that the increasing number of experienced post-doctoral and other short-term contract researchers (perhaps 10,000 in the UK) should find some security of employment. Mr P. C. Stephenson, Secretary of Science at the University of Sussex and responsible for Turner's employment, recognises the problem but feels that the Government and the Association of University Teachers (AUT) are responsible for creating a coherent national policy. "We are aware of the problem but we need to find the right place to start the argument," says Stephenson.

The legal position of contract workers became more complicated on 26 July 1977, when an Industrial Appeals Tribunal ruled in L. D. Dixon v. BBC that Dixon's contract was not fixed term during its tenure, thereby invalidating the waiver clause, but that it became fixed term at its point of expiration, thereby entitling Dixon to redundancy pay. In October of this year, an appeal court overruled the Appeals Tribunal and decreed that the waiver clause as customarily employed was valid.

Following this decision the AUT withdrew from Turner's case. However, Turner, with the aid of Brian Salter, chairman of the research subcommittee of the AUT's Sussex University branch, took his case to the tribunal hearing on 27 November, 1978. "We felt we still could make a case and we wanted the tribunal to commit itself to say that the appeal court ruling on Dixon v. BBC was relevant to research workers," says Turner. The tribunal has not yet made its decision.

Salter, who is encouraging researchers to press redundancy claims, agrees that a coherent national policy is called for, but says that the AUT is not sufficiently aware of the conditions of research workers. Salter feels that bridging loans betwen contracts, reorganisation of the nation's research into core areas located within universities and a well defined career structure alongside the normal university lecturer scales is needed. "The Research Councils will also have to accept that people have to be hired even when they get older", says Salter.

Salter and Turner both think that a closed union shop may be the only way for short term contract workers to get any control over their jobs at all. "Under conditions where there are so many out of work scientists, the jobs will go to the cheapest bidder to the detriment of us all", says Turner.

The case of Dr Amiram Ur, being heard again last week in London by an industrial tribunal after two months adjournment, also raises fundamental questions. In July 1974, the MRC introduced 'Establishment Code 335' which radically revised the career structure for non-clinical staff. Citing the greatly reduced university job opportunities as a reason, the MRC instituted a procedure under which, after four years, "awards of unlimited tenure will be made on average to 75% (taking one year with another) of the number of staff awarded limited-term appointments."

Approximately 600 people were affected by the order, which would result in 450 tenured posts but also redundancy for 150 scientists. Changes in the Establishment Code are negotiated agreements and as the negotiating body, the AUT is implicated in this ruling. But as one experienced observer noted, "This AUT negotiated tenure procedure is really a dismissal procedure and doesn't meet the minimum legal requirements of a dismissal system." Ur was one of the MRC's employees that came under the new ruling.

On 29 March, 1974, Ur was transferred from clinical to non-clinical status which brought him under the new requirements imposed later in the year. In November 1976 Ur's mandatory application for tenure was denied and under the new terms of service was given a year to find another job. Ur protested the decision citing deficiencies in MRC procedure beginning with his transfer to non-clinical status. This failing, Ur was dismissed in November 1977. The first tribunal hearing on the case was scheduled for April 1978. After an MRC request for postponement, in June 1978 the MRC offered Ur a settlement, which included back pay, reinstatement on a three-year contract, legal costs up to £4,000, return of pension rights and an elaborate and costly procedure to "investigate the grievances for and against Dr Ur".

The grievance procedure provided for a three-person committee, one member selected by Ur, one by the MRC and a chair person by mutual agreement. In case of difficulty with the latter choice, nominations were to be received from the President of the Royal Society. The committee was to have a paid secretary and to have had the ability to call and pay witnesses. However, its findings were to be confidential to the MRC and council actions based on the report were to be final and binding. Ur refused the settlement.

Meanwhile, the hearings of Ur's tribunal are expected to carry over until March. ☐

Better Med than Dead

Vera Rich reports on Israel's plan to save the Dead Sea from drying up by building a canal linking it to the Mediterranean

ENVIRONMENTAL protection is normally one of the first victims of a war economy. It would be tempting, therefore, to interpret the Knesset motion tabled last month by former Foreign Minister Yigal Allon, to avert ecological disaster by constructing a canal linking the Mediterranean and the Dead Sea, as a sign of approaching political normalisation Ironically, this is by no means the case; indeed, according to some Israeli sources, the signing of a peace treaty with Egypt would effectively block any such plans.

The idea of such a canal is not new. It was first proposed at the end of the last century by Theodore Herzl, the Zionist leader who first envisaged a future Jewish state. Since then, a number of plans have been proposed, including a grandiose scheme for a ship-canal down from Haifa, viá the Sea of Galilee, lower Jordan and the Dead Sea, down to the gulf of Aqaba. Present plans, however, and there are five under consideration by the Israeli government, with three possible routes, concentrate rather on the possibility of using such a canal as a source of hydro-electric power which could produce up to 10% of Israel's present generating capacity

The Dead Sea lies some 400m below the level of the Mediterranean. Theoretically, therefore, such a canal could descend via a number of hydroelectric cascades. Such a project is highly favoured by Israel's anti-pollution lobby, notably by Dr Anthony Pirano of the Techion, who has worked out his own "integrated" scheme, with desalination of the water at the inlet end, and use of the proposed storage reservoir at Arad as a winter spa. Other proposals are somewhat less elaborate, but all would admit that the construction of such a canal would not be at present justifiable economically, on the basis of the energy produced alone

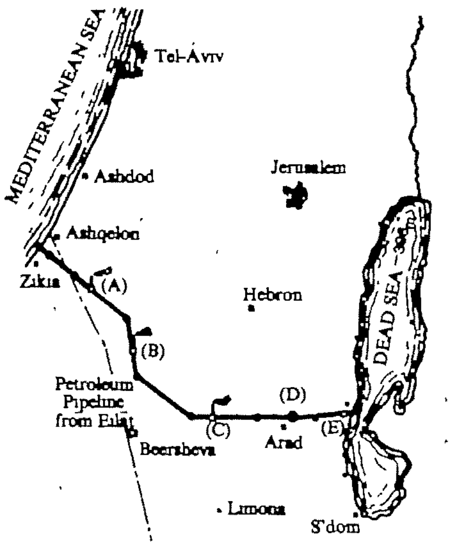
Replying in the Knesset to Mr Allon's motion, the Energy Minsiter, Yitzak Moda'i, stressed this point. Electricity, he said, can still be generated more cheaply by conventional power-stations using fossil fuels. The main purpose of the canal would not, however, be the hydroelectric scheme, although, as Mr Joseph Vardi, official spokesman for Israeli Ministry of Energy and Infrastructure told *Nature*, power production would be a spin-off which would make the canal economically feasible. Its prime purpose would be to recharge the Dead Sea

Of recent years, Israel's use of the Sea of Galilee as the water source of the whole country has led to a significant drop in the level of the lower Jordan and a consequent fall in the level of the Dead Sea. The arid climate of the Dead Sea region causes a high evaporation rate—a fact utilised by the Dead Sea potash plant at S'dom, which is based on the natural evaporation of brine from shallow pans. Already the receding shore-line has left the S'dom works some distance "inland," and it has been necessary to construct a new pumping station and canal to bring the brine to the evaporation pans.

Although the Dead Sea Works has thus solved their own immediate problem, this is no remedy for the ecological changes produced by the recession of the Sea According to Mr Allon, the situation is becoming "urgent" due to continuing progress by the Jordanians in their own water projects. The diversion of the Yarmuk river (a tributary of the lower Jordan) via the East Ghor canal for irrigation purposes is almost complete. Half the streams flowing into the Jordan from the east have already been dammed, and the damming of the remainder is proceeding at full speed. Once these Jordanian schemes are complete, said Mr Allon, the lower Jordan will dissappear completely, save as a drainage channel, the level of the Dead Sea will fall completely and the southern part of the present area of the Eea would become a salt desert This, as Mr Moda'i admitted in his reply, could cause "tremendous" ecological damage, which could not be easily repaired.

Use of the Jordan water by Israel's eastern neighbours has always been a sensitive issue. The "war over the waters" between Israel and Syria, was one of the prime causes of tension which led ultimately, to the Arab-Israeli conflict of 1956. Since it is not the loss of the lower Jordan itself, but the drying up of the Dead Sea that is seen as the ecological hazard, the construction of the proposed canal would clearly remove at least one potential cause of future conflict between Israel and Jordan.

A speedy separate peace with Egypt, however, would almost certainly force any such construction project to be deferred. Not for any political reason, but simply because Israel's resources, both human and financial are limited, indeed, overextended. Military withdrawal from the Sinai would entail the construction of new defence installations in the Negev.



Dr Pirano's proposed canal route

Furthermore, troops stationed in the Sinai have left their families at home, generally in the populous areas in the north If transferred to the Negev, however, they would probably bring their families south, with consequent development of such towns as Be'er Sheva and Dimona, as well as less fortunate settlements such as Yeruhanm which have never really become fully viable. Under such circumstances, Ben Gurion's vision of the Negev as the heartland of Israel's prosperity could well come true—but at the cost of resources which could be otherwise used for the proposed canal

According to some Israeli sources, there is considerable pressure "from outside" for a post-treaty Israel to develop a joint nuclear power capability with Egypt, the stations being situated in the Sinai, as a further incentive to peace. Such a project running into "billions of dollars" would be of considerable interest to foreign investors Israeli attitudes to nuclear power are generally cautious—particularly since the proposed coastal site for one nuclear station between Ashqelon and Ashdod (see map) was found to be earthquake-prone. Until now, however, costs have been too high for Isreal to considér any major nuclear power programme.

Should the proposed joint Israel-Egypt Sinai scheme become a reality, the proposed canal would be less important from the energy point of view, and with still more of Israel's construction workforce committed to the Sinai power-stations, its early construction would seem most unlikely.

The ecological threat to the Dead Sea would remain. It would be ironical if the peace-makers who urge Israeli-Egyptian nuclear cooperation should prove later to have laid the foundations for a second "war of the waters". ☐

Inflation forces new tactics on US environmentalists

LAST SUMMER the environmental sciences board of the US National Academy of Sciences prepared a list of topics requiring its attention. At the top of the list was the potential threat to schemes for environmental management and regulation posed by pressures on the economy, and the political measures which might arise.

The board's concern reflected a debate that has been simmering in Washington since President Carter's administration began its attempts earlier this year to take a "firm grip" on the problem of inflation. A major component of the ensuing debate has been whether environmental controls are inflationary; and if so, what should be done about them.

Concern among environmentalists erupted briefly at the beginning of the autumn when Mr Robert Strauss, then the administration's chief inflation fighter, let slip his view that environmental regulation was one of the first areas in which cut-backs could be made.

Since then the rhetoric has been softened. Administration economists now talk about the need to demonstrate the cost-effectiveness of proposed regulations; and both regulators and environmentalists have won a number of important battles. But they are now on the defensive.

On balance, 1978 has not been a bad year for environmentalist causes. Though backing away from some commitments, President Carter has put up a strong fight against many potentially damaging water projects opposed by groups such as the Sierra Club, and recently signed into law the preservation of large areas of Alaska.

Furthermore last week the Tennessee Valley Authority announced after years of opposition, that it was prepared to invest over $1 billion to clean up air pollution at ten of its power plants, a settlement described by the Environmental Protection Agency as "the largest ever made with a major source of air pollution".

However just as four years ago environmental regulations were being blamed for the problems of increasing unemployment, so the same is now being widely said about their contribution to inflation; industry claims, for example, that meeting new controls means taking away money from more productive areas of investment.

In reply, environmentalists claim not only that such regulations make a very small contribution to the increase in the consumer price index—estimated at less than 0.5%—but that if factors such as reduced health care costs are taken into account, the benefits of pollution control measures outweigh the costs.

"Most important, I believe that the public wants those benefits and is prepared to pay for them," says Douglas M. Costle, administrator of EPA. A recent survey conducted by Resources for the Future found that 62% of those questioned were prepared to pay higher prices to reduce pollution.

But to answer the charges being laid against the regulators, convictions previously expressed in qualitative terms are now having to be quantified. "We need to focus more on the adequacy of data, their interpretation, the need for risk-benefit analysis from a systems view," says Dr Gilbert S. Omenn, assistant director of the President's Office of Science and Technology Policy.

This need is reflected in the shifting strategies of environmentalist groups. Initially reluctant to place quantifiable values on that which they are trying to defend, this is now becoming necessary to respond to proposed "anti-inflation" measures. The Natural Resources Defense Council, for example, one of the strongest such groups, is setting up a working group on the economics of the environment, and others are moving in this direction.

> **'We are going to insist on better data on the cost-effectiveness of environmental control measures. I do not see this as necessarily bad, unless the pendulum goes too far'**
> —Prof John Cantlon

A major problem, however, is that whereas the likely costs of any new regulation are relatively easy to predict, the same is not true for the other side of the equation. "There is no question that trying to get at the benefits side of the picture is a very much tougher job of analysis and study," says Professor John E. Cantlon, professor of botany at Michigan State University, and chairman of the NAS's environmental sciences board.

"However it is something that needs to be done. The scientific community should not stand around wringing its hands, but should start getting research groups interested in the problem," he says.

"The climate in government and in industry broadly—and I would even say in society—is that we are going to insist on better data on the cost-effectiveness of environmental control measures. I do not see this as necessarily bad, unless the pendulum goes so far as to call into question genuine concerns about internalising the social costs of production."

Others are concerned at this happening. Speaking at a meeting last week organised by a group called Environmentalists for Full Employment, Ms Peggy Seminario, an industrial hygienist with the American Federation of Labour and Congress of Industrial Organisations (AFL-CIO), claimed that many companies were using inflation as an excuse to resist further regulation, often using suspect data to support their arguments.

"At the heart of the debates on cost estimates, there are not many numbers, and the numbers are not that good. In 1974 environmental impact statements claimed the cost of meeting proposed vinyl chloride standards would be between $65 million and $90 million; recently, after the standards were introduced, it has been estimated that the costs to industry of meeting the regulations was less than $1/2 million."

But the increasing incursion of economics into the environmental debate is also raising difficult issues within the environmentalist movement. Some have argued, for example, that the price of energy should be allowed to rise so that solar energy, already environmentally preferable to more conventional sources, can become economically competitive as well.

Others dispute this strategy, claiming that any increase in energy prices has an unfair impact on the poor. "The net result of present policies is to force people at the low end of the income distribution to lose food to pay for solar energy," Dr Gar Alperovitz, co-director of the Exploratory Project for Economic Alternatives, told the EFFE meeting.

"It is time for the environmental movement to take responsibility for what it is saying. We must reconsider the relation between strategies on prices and the desirable goals of conservation; for example there are other ways of getting to solar energy than by supporting higher prices."

Whichever way the various debates go, they seem destined, in Washington at least, to be increasingly fought on a terrain of economic argument which few can afford to ignore. As one Congressional aide put it last week: "Economists now seem to be playing the same role in Washington that scientists used to play in the 1960s."

David Dickson

news in brief

● **Death halts Greenpeace action over nuclear waste:** The first ship to carry nuclear waste from Japan to the reprocessing plant at Cap de la Hague near Cherbourg in France, has had to alter course for Barrow-in-Furness in England after one of its senior technical experts, Mr Robin Dale Hartley, died. Preliminary reports suggests that he died of a heart attack while in his bunk. Mr Hartley was an electrical engineer responsible for maintaining the cooling systems of the 26 containers of fuel rods of uranium oxide aboard the Pacific Fisher. British Nuclear Fuels Ltd, which had chartered the vessel, said that it expected that an inquest into the death might be necessary.

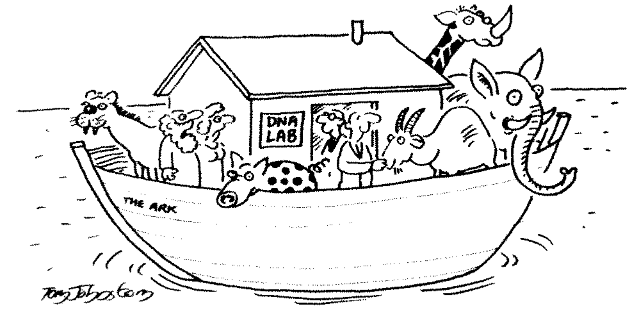
The consignment of nuclear waste is to be reprocessed at Windscale in Cumbria and at Cap de la Hague, under the terms of a contract between Britain, France and Japan by which each of the two European countries is to reprocess 1,600 tons of Japanese uranium oxide over a nine-year period from 1982. Although Britain has been taking nuclear waste from Japan since 1969, this is the first consignment to go to France.

The Greenpeace conservation group had planned to harass the Pacific Fisher as it entered Cherbourg, as part of a demonstration against shipping nuclear waste to France which involved 18 different French anti-nuclear and other political organisations. They were going to use their converted trawler the Rainbow Warrior which successfully frustrated the seal cull in the Orkneys last October.

Mr David McTaggart, European director of Greenpeace, said they were planning to run inflatable dinghies in front of the Pacific Fisher. Even though the ship is not going straight to Cherbourg, Mr Peter Wilkinson, Greenpeace director in charge of the anti-nuclear campaign, said they were still going ahead with a demonstration with the French organisations, but they were not going to demonstrate at Barrow-in-Furness, in deference to the dead man's family.

● **Museum can show Darwinian evolution:** The Smithsonian Institution's National Museum of Natural History is not required to depict the Biblical version of the creation of the universe as part of a scientific exhibition on evolution, a court in Washington ruled last week. Two religious groups claimed that a $½ million exhibition, which opens next May, violated the Government's role of religious neutrality by presenting Darwinian evolution as "the only credible theory of the origin of life". They asked the court either to ban the exhibition, or to require the museum to spend a comparable amount of money illustrating the Biblical account of the origins of man.

In rejecting both claims, US District Court Judge Barrington D. Parker said that the primary effect of the evolution exhibits was not to advance a religious theory, or to inhibit plaintiffs in their religious beliefs. "Even accepting their argument that evolution is hostile to their beliefs as to creation, this impact is at most incidental to the primary effect of presenting a body of scientific knowledge."



"Maybe it wasn't such a good idea to take along the two scientists!"

● **Thumbs up for re-usable satellite:** A favourable report on Britain's involvement in the MRS re-usable satellite project is now being prepared by a Science Research Council team and is to be presented to the council's astronomy, space and radio board in the new year. The Multi-discipline Refurbishable Satellite project, which could allow different instrument packages to be replaced while a spacecraft is in orbit, makes use of the Multi-Mission Satellite (MMS) being studied by the Americans. If it is given the go-ahead by NASA, this would lead to the setting-up of a joint UK-US feasibility study that could see the development of the revolutionary new satellite at a cost of several tens of millions of pounds.

Recently a team at the SRC's Appleton Laboratory, in collaboration with British Aerospace engineers at Stevenage, has been considering the most testing shapes and types of various scientific instrument packages that would have to be fitted to the craft. And it is now known that no serious drawbacks have been found to the various tricky configurations considered and a favourable report is to be presented to an informal meeting of the ASR board on 10 January. A more detailed report is likely to be presented to a future formal meeting of the board.

● **First evidence of gravity waves:** A team of astronomers at the University of Massachusetts at Amherst claims to have discovered evidence of gravity waves, whose existence was first predicted in Einstein's general theory of relativity 60 years ago, but has yet to be demonstrated. Using the 1,000-foot diameter radio telecope at Arecibo, Puerto Rico, Dr Joseph Taylor, Professor of Astronomy at Massachusetts, Dr Peter McCulloch, on temporary leave from the University of Tasmania, and Lee Fowler, a graduate student, monitored the radio emissions from a pulsar, discovered in 1974, which is orbiting another massive object. According to the general theory of relativity, the orbiting pulsar should radiate gravitational energy which would cause the two bodies to move closer together and thus increase the speed of rotation, which is currently a cycle every eight hours. Relativity predicts that the period of rotation should decrease by one-tenth of a millisecond each year. The astronomers found that the pulsar has slowed down by four-tenths of a millisecond, ± one tenth, in the four years since its discovery.

The results were presented at the symposium on relativistic astrophysics at the Max Planck Gesellschaft Astrophysik in Munich this week. The research workers say that they have been able to rule out other factors, such as tidal movements on the two bodies, which might have caused the changes. Calculations of the periodicity of the pulsar, which circulates its companion at 0.1% the velocity of light, have been complicated by the fact that its orbit processes at a rate of 4 degrees a year.

One physicist pointed out last week that a rotating pulsar was an almost perfect system by which Einstein's theory could be tested, since his theoretical framework was based on the concept of observers with clocks—in this case the rotating neutron star—falling freely through space.

● **Correction:** In the article "Czech Chartists claim two died in nuclear accident" (*Nature*, 276, 7 December, 1978, p.551), the fifth paragraph should commence, "A year and six weeks later, however, disaster struck again (according to the Chartists)".

Science in China: is 'the bumpy road' better?

By Stephen Risch, Michael Hansen, Judith Weinstein, Theodore Goldfarb and Carol Cina

China is bent on a great leap forward in science and technology—but it should not be at the expense of its peasants or workers

Joseph Needham's articles on science in the People's Republic of China (31 August, 1978 page 832) are for the most part informative discussions of recent changes in the organisation and process of Chinese science. However, Dr Needham's report does not accurately reflect important aspects of the political-social history of the past few years in China, and as a result draws a somewhat unbalanced picture of the evolving role of science. This is largely due to Dr Needham's uncritical acceptance of the position of the current leaders with regard to the role attributed to the "Gang of Four" (G_4), especially with respect to their influences on science and technology.

A delegation of 12 members of Science for the People[1] visited China from 4 June to 2 July at the invitation of the Scientific and Technical Association of the PRC to study scientific and technical decision-making in agriculture and food production. We travelled from Hainan Island in the south to as far north as Peking, visiting universities, research institutes, People's Communes, and factories and interviewing researchers, peasants, workers, and local and national officials. We saw much evidence of the Chinese leadership's decision to place great emphasis on science and technology to accelerate modernisation. We would like to analyse some of the important points made by Needham and present a somewhat different view of the way science is developing in China.

Needham essentially repeats the current official line in China that the G_4 caused the economy to stagnate, that their ideas were heretical to all Maoist thought, and that they nearly brought science and technology to a standstill. For instance, he agrees with the assertion that the G_4 "brought the economy to the brink of economic collapse". This simply was not so. Between 1965, the last year before the Cultural Revolution, and the most recent years for which we have estimates, production of electricity increased 157% (1974), production of steel 162% (1974), coal 76% (1974), oil 619% (1975)[2], and machinery 350% (1975)[3]. Overall industrial production was 7% higher during the first half of 1976 than in the same period of 1975[4].

Needham asserts that "the cutting off of funds for all higher institutions was, under the G_4, a matter of course", and "necessarily in alliance with this was a general despising of science and scientists". We obtained quite a different picture. Needham says the G_4 exercised a dominant influence in China during the years 1974–6. We received detailed accounts of a number of large-scale research projects that were underway then at Chungshan University and the Institute of Entomology in Canton, the Institute of Zoology in Peking, and the Shanghai Academy of Agricultural Sciences, including some that were initiated during that period.

One of the institutes that Needham singles out as having suffered most from the G_4 was the Natural Tropical Products Research Institute on Hainan Island. When we visited the Institute we found that most of the research was stopped in 1965 for eight years, that is, before the Cultural Revolution had even begun. Students and staff returned to the institute in 1973, and vigorous new research programmes started in 1975 (during the peak of the G's influence).

This example serves to illustrate a general observation we made during our visit. The Cultural Revolution clearly had a profound influence on the organisation and practice of science in China, and in many cases the level of scientific activity at research institutes and universities was slowed up or interrupted. Most researchers spent some time living in the countryside with the peasants and they devoted a considerable amount of time at their research institutes to political discussion. These policies were not instituted by the G_4 in order to punish scientists. Rather, they were principled policy decisions made by the Chinese leadership to discourage the development of a scientific elite divorced from the needs of the people and to reverse the progress already made toward that end. (This does not mean that at the local level these policies were not occasionally used as a method of punishing particular individuals; we were told that this happened.)

The redirection of science and technology was initiated at the very onset of the Cultural Revolution in 1966. In certain respects, such as the demystification of science, the decentralisation of scientific decision-making and emphasis on the practical rather than the theoretical, the new policies were a continuation and intensification of those introduced in 1958 during the "Great Leap Forward".

What is more important than assigning blame (or acclaim) to individuals for a certain science policy is to analyse what the effects really have been and will be in the future. We learned that there is still a significant difference of opinion on the costs and benefits of the Cultural Revolution.

Many scientists we talked to thought that their experience of working in the countryside had been very valuable in developing a consciousness about the needs of the peasants, whom they are supposed to be serving. They developed ideas for their investigations by discussing their work with peasants, with whom they established continuing and mutually productive intellectual exchanges. For example, Li Li-ying, head of the Institute of Entomology in the outskirts of Canton, told us how the Laboratory of Biological Control gets most of its research ideas from nearby communes. Research begun there in 1974 is centred on ways to increase the natural population density of a predator which feeds on red mites, a common citrus pest. Tang Yuan, a weed control specialist at the Shanghai Academy of Agricultural Sciences told us that before the Cultural Revolution his research work, based on techniques developed in foreign countries, was rejected by the local peasants as unsuited to the conditions in Chinese paddy rice fields. When he began to work alongside the peasants and respect their knowledge about the problems that need to be solved he discovered a suitable herbicide which is now widely used in the Shanghai area. He now believes that intellectuals should integrate themselves with workers and peasants.

We also heard complaints however, from some scientists and technicians concerning their experiences during the

Manual work for students and scientists was policy not punishment

Cultural Revolution. They complained of serious interruptions to their research work by long periods of manual labour. In some cases no use was made of the training and skills of these researchers. We could not find out why the treatment of these individuals was so different from others.

Two universal complaints we heard were about the deemphasis of theory and a nearly total disregard for foreign scientific developments. While we are pleased with the reversal of these policies by the present Chinese leadership, our discussions raised some serious questions about potential problems that may result from the present drive to develop rapidly a large scientific and technical workforce as the key to modernisation by the year 2000.

First, we were told that a system of "key" schools (including secondary schools, universities, and agro-technical colleges) has been re-instituted. Set up at the national, provincial, and county levels, these schools are endowed with better facilities and faculty than most schools and their function is to channel the "brightest" students into the best schools in the hopes of rapidly producing a large work force of better scientists and technicians.

In addition, a system of nationally standardised exams was reinstituted this year. We were told that the results of these exams will be the most important criteria in deciding which students go to universities and which are sent to key schools. Further, the old requirement of students spending one or two years in manual labour before pursuing advanced studies has been dropped. Vice chairman Teng Hsiao-ping said in his 18 March speech, "Those who labour, whether by hand or brain, are all working people in a socialist society". Some scientists we spoke to agree with this idea. Others, however, suggested that all intellectuals benefit from manual labour and contact with the masses. We also learned that the government has decided to give special perquisites such as higher wages and better living conditions to scientists.

Associated with these policy changes is the danger of the development of a scientific elite that will become separated from the masses and do work unconnected to the needs of the peasants and factory workers. During the years of the Cultural Revolution there was much concern about the possibility of such an elite developing in China, as had happened in the Soviet Union. The fact that China was a society in transition to socialism meant that social classes still existed. Before the Cultural Revolution most scientists and technicians came from the upper classes. Thus, at that time, the leadership saw the division of mental and manual labour as a form of class antagonism with the upper classes performing primarily mental labour and the peasants and workers primarily manual labour. Consequently, they emphasised the need for scientists and intellectuals to engage in political study and perform manual labour alongside the masses so as to better understand their living conditions and be reminded of who their knowledge and science should be benefiting. Virtually everywhere we went this summer we were told how important it was that scientists develop a proletarian outlook so that their work would serve the needs of the people, but some of the new policies seem to conflict with this goal.

Throughout our trip, however, we did see evidence of integrating science and technology with agricultural and factory work. An excellent example of this is China's Four-Level Agro-science Research Network. This network involves agricultural workers in research and decision-making in agriculture-related science work. It consists of a county level research institute and a team of agricultural technicians and trained peasants for each county, commune, brigade, and production team[5]. The teams of technicians are engaged in agricultural research, agro-science, education, and popularisation of both the results and the methodology of scientific farming. We studied the network in detail in Wu county, Kiangsu province. Eighty per cent of the counties in China have been similarly organised since the networks were initiated in 1974.

We would like to emphasise that we did see considerable evidence that science will continue to serve the people of China. Yet, the political turmoil of the Cultural Revolution has subsided over the last several years. In its place, there has been an increased emphasis on stability and economic growth. Both Dr Needham and the editor of *Nature* apparently view this as a positive development: "So what do the Chinese scientists need most at present? They certainly need a period of many years of tranquility, away from the limelight of political attention . . . Science cannot survive intact given such a bumpy road". We are not so sure.

If one measures progress in science only in numbers of publications, research projects and highly trained scientists, perhaps they are right. At one time at least, however, the Chinese decided that this was not to be the measuring stick for their science. Rather they said that the best science comes from researchers who are fully integrated with other workers in the society and who are committed to serving the needs of the broad masses of the population. At times this may slow down the rate of scientific growth, as measured by Western standards. During the difficult transition to a socialist society, it may be that the "bumpy road" is the only way to achieve this alternative vision of science. Developments in China during the next few decades may help answer this question. □

Frelimo concentrates on the practical side of science

Pamela Smith and David Wield recently spent two years in Maputo at the Ministry of Health and the University Eduardo Mondlane. Here they assess the state of science in Mozambique

MOZAMBIQUE, independent since June 1975, almost ten years later than most of her northern neighbours, spent this last decade of Portuguese colonialism fighting an armed liberation struggle. The necessity to gain independence through fighting Portugal, herself a backward country, had some positive aspects. By independence, for example, Frelimo policies were already clearly formulated and tried out in the 'liberated zones' of the north, which covered about one-third of the country's total surface area. These policies had obvious implications for higher education and research and as such for science.

Higher education was to exist therefore, not to train a small elite in advanced techniques, but to "permit access to scientific and technical knowledge by the peasants and workers, for them to be able to assume economic power and increase production for their own benefit." This statement was issued as part of a policy document emanating from a National Seminar on Technical Education, held in December 1975. It is further reinforced by the report of the Central Committee of Frelimo to the third congress in February 1977, stating that "In education, it is indispensible that we continue to promote a constant increase in technical and scientific knowledge among the labouring classes and guarantee their access to the higher levels of education." This position originates from early on in the history of Frelimo, when in 1968, the only Frelimo secondary school, based in Tanzania, was closed after students refused to go into the 'liberated zones' for their holiday activities, demanding instead higher education opportunities in foreign countries, far away from the realities of the armed struggle.

Policy in independent Mozambique continues to be formulated by Frelimo. It is then analysed at the planning ministry responsible, as its name suggests, for coordination and overall planning, and by commissions, including members of the various ministries, such as education, health, agriculture, industry, concerned with particular areas of study. Before any plan is made, discussion takes place at all levels, including the individual institutions, such as factories or schools where representative committees will have been elected. In a factory, for example, the workers elect a workers' council, which has responsibility for suggesting measures to improve safety at work, or to increase productivity and quality of products. They may also make suggestions for the type of training courses required for different grades of personnel from inservice to undergraduate programmes. Proposals are then made on the basis of discussion reports received by the Planning Ministry and analysed once more at ministry level. Any criticisms or further suggestions are then directed back to the planning ministry. This two way process between the centre and the periphery is very important to keep policies based on everyday realities.

Mozambique is now coming to the end of the second year of her three year plan, outlined during the third party congress in February 1977. The plan's overall objective is to raise the economy to pre-independence 1973-levels, and to develop by 1980 the basic structure for the next period of national reconstruction. The plan, as it relates to science, is taking place on two levels : first in education, where as many people as possible are to be provided with the technical and scientific skills necessary to the development of the country; and second through research mainly in certain priority areas, such as geology and crop production. Unlike many other third world countries, Mozambique does not possess a national science policy research council. Science policy is seen as an integral part of an overall plan, and as such, statements related to research can be found in the economic and social directives in the third party congress documents.

How can the two level objective be put into practice, given the colonial education system which gave only 5-10% of Mozambique's population the skills of reading and writing? Or which set up a few luxury secondary schools and a university in Maputo (formerly Lourenço Marques) for the Portuguese settlers and a handful of African and mixed race 'Assimilados'? Research done at the university and government research institutes, was for the most part irrelevant to Mozambique's needs and only questionably useful to the colonial power herself. Portugal, though poor and backward as a nation, under the Salazar and Caetano regimes, was bent on the pursuit of a high level of research to gain international prestige. Even in the Mozambican agricultural sector, with large exports, research was very restricted in comparison with neighbouring colonies like Tanganyika, which at least had competent research programmes and well staffed institutes for the major export crops such as sisal, coffee and cotton.

Camera Press

The president of Mozambique, Samora Machel, said when visiting the university in May 1976, "It is not by chance that we find that our university engineering graduates working in generating stations cannot begin to repair a generator, and medical professors who have difficulties diagnosing simple illnesses of the local population". Not only was the top scientific education that Mozambique had to offer at independence virtually useless for national reconstruction, but the schools' system was also highly theoretical and restricted to a minority, leaving an illiteracy rate of over 90%. Only those in the elite 'liceu' secondary schools could enter the University. Those in the industrial and commercial secondary schools, had to be satisfied with technician training in lower level technical institutes.

It is for this reason that in the early years of independence priority has been given to building the educational base, particularly in the rural areas. Crash literacy programmes have begun using not only school and university students but also those who are themselves barely literate, to teach those who are not. The primary education system, which takes four years to complete, has trebled since 1974 and now about 1.2 million pupils are registered.

0028-0836/78/0276-0751$01.00

New schools are often set up through local initiative, and in the absence of buildings pupils can be seen learning beneath the trees of many Mozambican villages.

At independence, the secondary schools shrank rapidly as the Portuguese settlers left, but there are now over twice as many schools and pupils as in 1974. In the university, founded in 1962, the student population of over 2,000 in 1973 diminished to one-quarter of this number in the early independence period. University teachers and technicians also left in great numbers, being part of the settler and 'assimilado' population, with the result that faculties and research institutes were denuded of qualified personnel.

Further data on scientific training, manpower and budgeting is difficult to obtain. Colonial statistics were either incorrect—for example, the last population census in 1970 underestimated the population by over 20%—or non-existent. Mozambique is one of the few countries in the world with no government estimate of gross national product. However a national statistical centre is in formation this year, and a national accounting system will be organised by 1980. More comprehensive educational tatistics are being collected this year but are not yet available.

Nevertheless it is possible to estimate that there are now 200-400 Mozambican graduate-level scientific workers, mostly involved in agriculture, health, education and engineering. The majority of these are under 30 years old, and were trained in the pre-independence period. They therefore had to make a positive decision to remain in Mozambique, helping to keep services running amid the initial confusion that ensued as many of their colleagues left for Portugal. There are a few Mozambicans with postgraduate qualification from Portugal, South Africa, England, France and USA. As the policy of the government was to keep the university and research institutes going, these Mozambican scientists find themselves working alongside a considerable number of foreign scientists, some of whom remained from the pre-independence period to help national reconstruction, as well as those recruited since 1975 from socialist and progressive countries and groups.

The university and research institutes work under the general orientation of the ministry of education, placing their 'human and material resources . . . at the service of the social and economic priority sectors", as defined during the third congress. A scientific worker may therefore find him/herself engaged in curriculum planning, teaching university students and technicians, organising fieldwork and research projects and serving on interdisciplinary commissions at ministry level. Within the university, some changes have been effected. Courses have been reduced from five or six years' duration to three. In 1975, for example, the final year agronomy students decided that they did not wish to graduate until they knew something of the agricultural reality of the country. Instead of graduating, they volunteered to work in the countryside for a period. Other courses have since become more practically orientated. Last year, for the first time, chemical engineering students learned control engineering and smelting practice, in local factories as well as in the classroom. Previously, they would have conducted routine experiments solely within the laboratory and studied theoretical mathematics and physics. Hence for example, complex atomic theory has now been withdrawn from the curriculum, permitting a greater emphasis on more relevant theoretical and practical work.

Literacy is the educational priority, particularly in rural areas

In addition to existing courses, university teachers have been asked to set up new ones for lower level students. Some of the teachers were unhappy, but the majority perceived a way of changing elitist attitudes in the university. Pre-university courses for workers and crash teacher training programmes have begun. Only about 20% of the students are fulltime, the others provide technical backup in the ministries, schools, factories and other government institutions. The university's function was described by the president as having "to leave its doors and go to the factories and villages, putting its techniques at the service of national reconstruction. There it will learn new techniques from practical life. This will stimulate the study of scientific realities, not in an abstract way, but in a creative manner, linking its knowledge to the material wellbeing of the population."

New research priorities and methods of working have thus emerged. As already indicated, there is a close link between the university and the various ministries, particularly in the field of scientific research. Scientists are working in the ministry of health and the faculty of medicine; others are based in the agronomical and veterinary faculties, the ministry of agriculture and two research institutes in Maputo or small up-country laboratories.

One specific example of the type of research project that is being undertaken in Mozambique, is in the field of traditional medicine. Two hundred plants have already been collected which traditional healers claim have medicinal properties. Library research is currently being undertaken by a commission in the ministry of health, to see what is known about them. It is already clear that most traditional treatments for diarrhoea contain tannin. Within a short period, some plants which the literature search suggests are safe, will be tried out, not by extracting the active ingredients and turning them into modern pharmaceuticals, but by encouraging rural health workers to use them in the traditional manner, such as in tea form.

In the university, research has been geared to seeing how technology can be adapted and used according to priority needs. One final year student of chemical engineering carried out an important project on charcoal production, charcoal being the fuel used by the majority of Maputo's 800,000 population. Deforestation of the surrounding areas of the city seems to be one of the problems resulting from present production methods. Her work was to look at these methods not only to see how to improve their efficiency, but also to check on possible extraction and use of methanol and ascetic acid from wood distillation, since Mozambique does not produce either of these chemicals. She was also investigating the effect of centralising production on family level charcoal producers, dependent on this for their livelihood. This project has since been integrated into the planning of a larger project, based on the ministry of agriculture's forestry department. Also within the university, an appropriate technology unit has been set up, working on problems such as methods of grain storage, food preservation and water purification, especially relevant to the rural areas. In the ministry of agriculture, soil studies have begun as have studies of local foodstuffs and their usefulness for poultry rearing.

Sometimes, useful research results come unexpectedly. A recent study on the extent of migrant labour from Mozambique showed that returning labourers have technical skills which are in short supply. Another example is the national vaccination campaign, which is almost complete, having begun in 1976. Mobilisation has been extremely good and WHO estimate that already 92-96% of the population has been vaccinated against smallpox, tuberculosis, DPT (Diphtheria, pertussis, tetanus) or measles, depending on age. The 1970 census figure of 8.3 million has already been exceeded and estimates expect final totals to be in the region of 11 million. The vaccination campaign also gives demographic information on the age distribution and density of the population. In the past four years, Mozambique has been able to restructure its educational system placing the main emphasis on basic skills. Its higher scientific manpower, small in number, has been actively involved in this restructuring in teaching, planning as well as research. Teaching has become more practical, planning has had to take into account national priorities and research has thus been research with a small 'r', requiring only restricted laboratory and library facilities and using students as well as teachers.

This year, one of the priorities of the university and government research institutes has been to plan for research in the medium term that is for the next planning period beginning 1980, not as until now, on a short term basis. Stricter planning is required and the lessons learnt from the last few years, are being analysed in detail so that improvements can be made ensuring that research tasks are put more, not less, into line with national priorities.

The Mozambican government continues to recruit scientists able to work in various fields. Those who feel that they may have relevant skills and could be useful in the Mozambican context, should write to: — The Mozambique Information Centre, 34, Percy St., London W1P 9FG, Telephone No. 01-636 7108 who coordinate recruitment in Britain and would be happy to receive enquiries. ☐

'By nature not nurture' they sang . . .

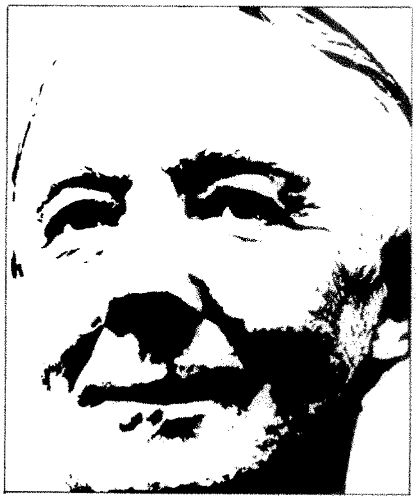
AT THE recent International Conference on the Unity of the Sciences in Boston in the United States of America, the life sciences committee, of which I was chairman, had a useful, calm and objective discussion on genetics and society, when the importance of inheritance and environment in man was considered. One of those present was Professor Arthur Jensen from the Institute of Human Learning of the University of California. At the end of the meeting he said that he had been very favourably impressed by the behaviour of the discussants and of the audience; all shades of opinion had been expressed without fear of interruption. He compared this experience to that obtained before audiences in universities in America and Europe, where certain left-wing groups have disrupted the meetings, saying that these topics should not be investigated or publicly debated.

It is interesting to note the changes which have occurred in the attitudes of the politically motivated in this field. In the 1920s there were many Socialist Sunday Schools in Glasgow, Scotland, where young people were nourished in what was then considered to be pure Marxist doctrine. Techniques of instruction familiar to the audience, many of whom had previously attended Church Sunday schools, were used. They listened to "sermons" and sang secular "hymns". One favourite hymn included the lines:

"By nature not nurture we'll rise
to the skies
The means of production we'll
nationalise."

Although nationalisation may still remain within socialist political programmes, views on nature and nurture appear to have changed. Fifty years ago those running the Sunday schools took the view that those of their pupils with innate, inherited ability would triumph over the effects of their unfavourable environment. In fact they believed that the effects of heredity could be even more important than those of the environment, if the individual then received the appropriate type of education. Professor Jensen and others have, in recent years, been vilified for suggesting that this may still apply.

There has also been a change in attitude to the use of Intelligence Quotients (IQs). Left wing opinion



KENNETH MELLANBY

condemns these as instruments in promoting racism. However, at one time these were considered the fairest method by which bright children from poor educational backgrounds, who found conventional examinations difficult, might be admitted to grammar schools. The intention was not to show that the underprivileged were stupid, but to give them a better chance to develop their potentialities.

I found IQ tests to have some value when selecting students to admit to the first university courses we started at Ibadan in Nigeria in 1948. Our infant university could only admit a very small proportion of those who applied. Nigerian schools at that time were very variable, ranging from the government colleges which compared with grammar schools in Britain, to those run privately with few trained staff. We set what were then considered conventional written papers in arts and science subjects, and I also gave each candidate an IQ test. Most entrants were selected on the results of the written papers, and none whose marks where above an arbitrary minimum was excluded, but I also admitted a few who did badly in written work but who had high IQ scores.

I am glad to say that members of this latter group almost all did well in their later university courses. In fact I found that, for all students, their results in their degree examinations correlated better with their IQ figures than with their marks in the entrance examination. Incidentally the IQ scores of our successful Nigerian students were in the same range as those found with white undergraduates I tested in Britain, so these findings should not be offensive to those who, for political reasons, oppose this type of investigation. ☐

Biochemical nomenclature

Sir,—Every biochemist knows the frustration of being told to use a new name for a substance when he was perfectly happy with an old one. It can, however, be just as frustrating when different groups of workers use different nomenclature systems. Widely agreed recommendations may, at the very least, prevent a name from implying an incorrect structure; they may even indicate correct ones.

Slavish adherence to fully systematic nomenclature gives unusably long names; at the other extreme laboratory jargon is understood only by the initiated. There is therefore a need for specialised nomenclatures in many fields to compromise between the needs of the workers in the field and more general readers.

A difficulty in the past has been that names may be established before it is realised that they are misleading or ambiguous to those in related fields. A glaring example of this is 'diphosphate'. This was long used to mean two phosphate groups, and also, as in ADP, a single diphosphate group. The latter usage has been approved, and two separate groups are now distinguished by being called 'biphosphate' [strictly bis(phosphate)] as in fructose 1,6-biphosphate.

Much of the difficulty can be avoided if recommendations for a self-consistent nomenclature are agreed at the very beginning of the study of a new class of compounds. This is the thought behind general principles for naming natural organic compounds, prepared by the Commission on Nomenclature of Organic Chemistry of the International Union of Pure and Applied Chemistry (IUPAC) and published as: Nomenclature of Organic Chemistry, Section F, IUPAC Information Bulletin, Appendix 53, 1976 (*Eur. J. Biochem.* **86**, 1–8; 1978).

The basic idea of Section F is to have a set of stem names for each group of natural products to which the general principles of organic nomenclature will apply. Thus, unsaturation and the presence, type and number of functional groups will be indicated by prefixes and suffixes according to the standard methods of Nomenclature of Organic Chemistry, Section A–D, stereochemistry according to Section E and isotopic substitution according to Section H. Modifications of a skeleton will be shown by methods first introduced in the Steroid Rules, and now set out generally in Section F.

Although Section F is designed to guide individuals so that they can themselves propose a clear and simple system of nomenclature for a new class of compounds, there remain great advantage in bringing together many workers in a field to agree on how its general principles should be applied. The Joint Commission on Biochemical Nomenclature (JCBN), joint between IUPAC and IUB (International Union of Biochemistry), set up in 1977, has, as one of its main tasks, the application of these principles to appropriate groups of natural products. In this it works closely with the Nomenclature Committee of IUB (NC-IUB).

In some areas recommendations for nomenclature have already been made. In others JCBN will be inviting specialists who are active in the biochemistry and chemistry of particular groups of compounds to form working parties to make such recommendations.

We hope that our colleagues will accept invitations to serve on such working parties and carry out an important task. We hope too that specialists in areas that need agreed nomenclature will offer to form working groups themselves. We would be glad to hear of suggestions for topics from any groups in such areas that already meet for discussion. We would be glad to hear of suggestions for topics that may need nomenclature agreements, even when not accompanied by an offer to serve on working parties!

Has food production kept up?

Sir,—John Gribbin has referred (16 November, page 208) to FAO data indicating that in the past two decades, while population has grown at 2% per annum food production has grown by an average of 2.8% per annum. As I have pointed out elsewhere (*Proc. Nutrition Soc.* **36**, 121; 1977) such aggregate figures are highly misleading Whereas, in the developing countries, the total increase in food production was 2.8% per annum in the 1960s, demand for food increased by 3.5% in those countries. Almost two-thirds of all developing countries showed a fall in self-sufficiency in 1970–72 as compared with 1961–63.

Even more critical is the situation in the food-deficit less developed countries, in which grain production increased by 2.5% per annum in 1960–74 but only by 1.7% per annum in 1967–74. Analysis by the International Food Policy Research Institute shows that even if grain production in those countries were to increase by 2.5% per annum to 1985, they would by then have a deficit of 100 million tonnes of grain per annum. The trend over the past four decades has been of an increasing surplus of grain in North America and an increasing deficit in the developing countries. The problem, therefore, is not that of overall world food production but of where the food is produced, and of its distribution, both between and within different countries, and also whether it is used to feed animals or human beings.

Mr Moon's philosophy

Sir,—While I know very little about the ICUS of 1972 and 1973 and the organisation of Mr Haskell, it is ridiculous for Professor Nicholas Kurti (16 November, page 206) to place the ideas of Mr Moon on a par with those in Haskell's book "Full Circle: The Moral Force of Unified Science" where the latter postulates periodical tables for botany, zoology and sociology.

Professor Kurti seems to assume that he can simplify to the necessary degree to reach his conclusions situations which are extremely complex. The 'Give and Take' relation is a fundamental metaphysical principle and we are consciously or unconsciously dependent upon it. Mr Moon's philosophy asserts that the true unity exists in the Creator while in the creation there is only plurality even though it is ordered plurality. Mr Moon is concerned primarily with the order of life and with ordering life and he presents us with a conceptual apparatus which sets out many things to which we can relate in a gradual and ordered way.

I must explain that the ICUS meetings are not public relations ploys to further the Unification Church, nor are they frosting on Mr Moon's theological cake. Mr Moon founded the ICUS conferences because of his deep and sincere desire to set up a forum to further the striving of man to resolve "the most important problem of our time—the reconciliation of religion and science. The problem is not simply a matter of reconciling two academic disciplines. Rather the problem points to the need to investigate the dichotomy of facts (science) and values (religion and ethics). This separation of science and religion in the modern world has caused untold harm and serious damage to the development of humanity."

But while Professor Kurti himself says that the ICUS conferences should be judged by the contents of the published conference proceedings and not by selected remarks and others, his ideas about the teachings of Mr Moon's movement indeed echo the popular press. It would have been better for all concerned if Professor Kurti had consulted the official publications of Mr Moon's teachings and the activities of his movement.

Echoes of the bat's cry

from Jennifer Altman and Shin-Ho Chung

As the basic mechanisms of hearing are beginning to be understood, auditory physiologists are turning their attention to the neural processing of complex acoustic signals. From several recent studies on amphibian (Pettigrew *et al. Nature* **272,** 138; 1978), avian (Knudsen & Konishi *Science* **200,** 795; 1978) and mammalian (Chalupa & Rhoades *J. Physiol. Lond.* **270,** 595; 1977) species, we now know that auditory space is accurately mapped onto a nucleus in the midbrain, while neurones in the higher cortical centres are specifically tuned to extract certain features of sound. As might be expected, those animals which rely mainly on their ears for survival have the most highly developed auditory brain, and slowly neurobiologists are unravelling the neural mechanisms by which such animals handle acoustic signals.

Of the several known species which construct a picture of the external world by listening to echoes from ultrasonic pulses, bats are the best known Each species of bat has its characteristic ultrasonic cry. Some, such as the little brown bat (*Myotis lucifugis*), use cries which are frequency-modulated, changing in pitch from high to low, whereas others, such as the moustache bat (*Pteronotus parnellii rubiginosus*), emit a cry of constant frequency, which tails off with a brief downward change in pitch. As the animal approaches the target, the emission rate of its cries increases, and the duration of each cry is shortened. From the echoes of its cries, the animal then gauges the size, distance and velocity, as well as the location, of the object ahead of it. Such an unorthodox way of seeing the external world is extremely efficient, as demonstrated by the agility with which bats avoid moving barriers (Jen & McCarty *Nature* **275,** 743; 1978), and the accuracy with which they catch their prey. It is estimated that a bat on a hunting spree catches about 500 insects per hour.

Several recent studies on the horseshoe bat (Möller *et al. J. comp. Physiol.* **125,** 217, 227; 1978) and on the big brown bat (Feng *et al. Science* **202,** 645; 1978) show how cells in the midbrain nuclei respond immediately to the distance of an object gauged by echolocation. In the auditory midbrain, there is a class of neurones which discharges only when an ultrasonic pulse mimicking the animal's cry is followed by a faint echo. These neurones are particularly sensitive to the delay between the pulse and echo, and different neurones are tuned to different ranges of pulse–echo delays; the optimal delay for eliciting discharges varies from 4.5 to 20 ms, which corresponds to target ranges from 0.75 to 20 m. Indeed, the entire midbrain appears to be elaborately designed to extract information from a pair of stimuli. Möller (*op. cit.*), for example, showed that the presentation of a first tone briefly enhances the sensitivity of the midbrain neurones, so that a faint echo following soon after can effectively be detected. The precise excitatory and inhibitory neural network underlying these observations remains to be elucidated.

In a series of studies on the moustache bat, Suga and his colleagues have demonstrated that a large part of the auditory cortex is devoted to detecting a slight shift of frequency components of the returning echo compared with the emitted cry (Manabe *et al. Science* **200,** 339; 1978; Suga *et al. Science* **200,** 778; 1978; Suga *Fed. Proc.* **37,** 2342; 1978). This Doppler shift contains information about the relative velocity of the animal and the target, and a remarkable behavioural adaptation enables the bat to utilise the specific tuning of its auditory neurones to the full. When the frequency of the returning echo is shifted to, for example, 63 kHz from the emitted frequency of 61 kHz, the bat reduces the pitch of its cry, so that the Doppler-shifted echo frequency would be at 61 kHz, the frequency to which the inner ear is specifically tuned (Suga & Jen *J. exp. Biol.* **69,** 207; 1977) and to which a disproportionately large area of cortical surface is devoted. In the primary cortex, neurones responding to frequencies from 61 kHz to 63 kHz are ordered concentrically, with the area excited by a 61 kHz tone located at the centre and the surrounding rings of cells excited by progressively higher frequencies. In addition to frequency selectivity, each neurone in this area responds only to a very restricted range of sound intensity. Lines of isoamplitude are at right angles to the isofrequency contours, and each neurone has both a best frequency and a best amplitude. When the echo is faint, neurones located on the lower part of the auditory cortex respond and these are excited by inputs from both ears. As the intensity of the echo becomes louder, neurones located on the upper part of the cortex begin to respond. These units are directionally sensitive, as they are driven by an input from the contralateral ear and inhibited by the ipsilateral ear. In this way, the brain encodes the location and the velocity of a target.

Further towards the centre, there is a cortical region which is devoted to processing frequency-modulated signals. Unlike the Doppler-shift region, this portion of the auditory brain has only a vague tonotopic representation, but contains instead clusters of neurones with similar response characteristics. The stimulus parameters to which neurones respond are more specific. Some neurones, for example, respond best when the frequency-modulated sound is followed by a faint overtone of the first sound. Others respond only to a pair of sounds with particular combinations of frequency, amplitude and timing, similar to the delay-specific

0028-0836/78/0276—0755$01.00

cells in the midbrain. These neurones thus seem to act like feature detectors, and by comparing the spectral composition of echoes with the emitted signals, they may serve to detect the size and location of the reflecting object.

The study of the bat's auditory system is providing us with unexpected insights into how the brain is designed to utilise biosonar signals. The next task for researchers is to elucidate the intricate neural network that enables certain features of acoustic stimuli to be extracted, and the processes by which such connections evolve during development. Moreover, it will be of great interest to know how the middle ear of the animal is constructed so as to vibrate optimally at ultrasonic frequencies. Once this task is achieved, we shall be a step nearer to understanding the mechanisms of sensory processing and integration, for which the brain is most exquisitely designed.

Positrons at surfaces

from John Pendry

RADIOACTIVE sources provide a supply of positrons in the laboratory, and one of the applications of these particles is to studies of the solid state. In a recent Letter (Mills, Platzman & Brown, *Phys. Rev. Lett.* **41,** 1076; 1978) an important new advance in technique has been demonstrated: positrons can be controlled precisely enough to probe the surface of a solid on an atomic scale.

Conventional experiments use positrons straight from the source with energies of the order of an MeV, and fire them into the solid under study. Once inside, a positron interacts strongly with the electrons through Coulomb forces. Plasmons, collective oscillations of the electrons, rapidly dissipate the energy and in a very short time the positron has lost almost all its energy and momentum. Capture of the positron by its antiparticle, the electron, will eventually take place, producing a pair of γ rays with the disappearance of the positron and an electron, though the time for annihilation is long compared with the time to come to rest in the solid. By conservation of momentum the γ rays must have almost oppositely directed momenta, slight deviations from 180° being due to the relatively small but finite moments of the electrons with which the positrons annihilate. Measurement of the deviation, in experiments which look for coincidences of two γ rays, gives the momentum distribution of electrons in the solid, information which can be used to understand bonding of solids, and to measure the Fermi surfaces of metals.

An additional complication arises for insulators, where the positron's Coulomb potential is largely unscreened, and is strong enough to bind an electron into a hydrogenic state known as positronium. The positron will preferentially annihilate with its 'own' electron, and signals characteristic not of the solid, but of the positronium bound state, are seen.

Surface sensitivity in positron experiments came a step nearer when it was shown that the thermalised positrons can be re-emitted from a solid before they have time to annihilate. Unlike electrons, positrons tend to be repelled by many solids and if in diffusing around the solid they encounter a surface they will be expelled from the solid. The positrons do not acquire more than about 1 eV energy so are reasonably monochromatic and can be accelerated by electric fields to form a collimated beam with easily controlled energy (Canter, Mills & Berko *Phys. Rev. Lett.* **33,** 7; 1974).

The point is that positrons with only 100 eV kinetic energy have limited powers of penetration, typically a few tens of Å, and therefore can be used to probe surfaces on an atomic scale.

Mills, Platzman and Brown have performed the first experiments of this nature. They worked with clean, well characterised, single crystal surfaces of aluminium, silicon and chromium. The characterisation by LEED and Auger techniques is most important in surface experiments as contaminants can easily cover a surface and obliterate all of the clean surface properties. The energies of positrons re-emitted from the surface were analysed by applying a retarding field to the sample and measuring the increase in the number of positrons annihilating inside the sample. The spectra had two components: a sharp peak at very low energies due to positrons that had thermalised inside the solid, and a much broader distribution due to incompletely thermalised positrons. The latter component became more intense as the incident energy was lowered below 1000 eV, a consequence of decreasing penetrating power.

The sharp peak was seen in all the materials studied, beginning its rise at zero kinetic energy and having a width dependent on the solid: 0.5 eV for aluminium, 1.0 eV for silicon and 1.7 eV for chromium. Because the positrons in this peak have thermalised inside the solid, the peak cuts off at a maximum energy which is the 'negative affinity' the solid has for positrons.

Our understanding of positrons in solids and at surfaces is based on calculation and on some experimental annihilation rates and angular distributions. The new experiments will provide a more detailed picture of positron behaviour. Theories of the positron-solid force law such as that of Hodges & Stott (*Solid State Commun.* **12,** 1153; 1973) can now be checked, even to the extent of diffracting positrons from surfaces. The rate of energy loss of positrons in solids can be determined from the ratio of thermalised to unthermalised positrons emitted: accurate calculations are difficult especially when the positron is moving slowly. Some new problems present themselves. The width of the low energy emission peak is only of the order of 1 eV but this is still more than an order of magnitude larger than the thermal spread in energies. Simple theoretical arguments require that the positrons are accelerated normal to a perfect surface, and if inelastic collisions are excluded, emerge in a parallel beam with only a thermal spread of energies. Certainly this is the situation found for electrons in negative electron affinity systems. The emission process for positrons must be more complicated and is yet to be elucidated.

Finally, we can look forward to the more difficult experiment of detecting emission of positronium. Canter, Berko and Mills (*Phys. Rev. Lett.* **33,** 7; 1974) have shown that a large fraction of the positrons pair with electrons as they leave the solid and emerge as positronium. This pair-tunnelling process reminiscent of the interface between a normal and superconducting metal can be studied by measuring the angle and energy distribution of the ejected positronium. ☐

John Pendry is at the Daresbury Laboratory of the Science Research Council.

A hundred years ago

THE *Japan Mail* states that an astronomical observatory is to be established within the precincts of the Geographical Bureau of Tokio. The same journal also announces that telegraphic insulators, made at the village of Imari, in the province of Hizen, are of such good quality that they find large sale in Europe.

Discrepancies in claims for endothermy in therapsids and dinosaurs

from R. E. H. Reid

L. S. Russell's claim, made in 1965, that dinosaurs were warm-blooded animals, has since been supported chiefly by the work of de Ricqlès on bone histology, and in papers by Bakker on other topics. The concept of dinosaurian endothermy has been welcomed by some authors, and represented as established in a popular book by Desmond; but such workers as Feduccia, Thulborn and Charig have remained unconvinced, and have severely criticised some of Bakker's claims. As usual some disputed issues authors are mistaken, while some of identical evidence, but one of Bakker's later arguments involves a serious factual error, unless many other authors are mistaken, while some of the arguments used in different papers are inconsistent or contradictory.

Bakker's later views appear in summary in his popular article 'Dinosaur Renaissance' (*Scient. Amer.* **232**, 4; 1975), in which late (Middle and Upper) Permian reptiles from southern Africa are said to be exclusively therapsids. These are interpreted as endotherms, and as living in cold post-glacial conditions, which restricted large ectotherms to the Permian tropics. They are restored as possessing hair as insulation, and as able to stay active in winter snows. Even Triassic climates were supposedly not warm throughout the year, and large thecodonts (erythrosuchids) from the early Triassic of South Africa were therefore probably also insulated endotherms. The relevance to dinosaurs is that thecodonts are the group from which dinosaurs originated.

These claims are consistent with de Ricqlès' conclusions from bone structure (in *Morphology and Biology of Reptiles* (eds Bellairs & Cox), 123 (*Linn. Soc. Symp. Ser.* **3**, no. 3, London, 1976)), but, unfortunately, not with other evidence. Charig points out (*ibid.* page **65**) that glaciation of southern Africa was not Permian but late Carboniferous, and that the late Permian reptiles include various non-therapsid types, some of which (pareiasaurs) reached large sizes. There was even a large labyrinthodont amphibian (*Rhinesuchus*). This information is easily available from well-known textbooks, such as Romer's standard *Vertebrate Paleontology* (third ed., Chicago University Press, 1966) or Haughton's *Geological History of Southern Africa* (Geol. Soc. S. Afr., 1969). Even stranger, Bakker's earlier analysis of predator–prey ratios, in a paper published in *Nature* (**238**, 81; 1972), shows more than one-third of the total prey biomass for the earliest late Permian zone (*Tapinocephalus*) as consisting of pareiasaurs, and describes its therapsids (deinocephalians), with pareiasaurs, as "almost certainly ectothermic". Later treatment of early therapsids as endothermic is within the bounds of reinterpretation; but what has become of the pareiasaurs?

Bakker also gives two opposite pictures of gait in therapsids. In his study of tetrapod locomotion (*Evolution* **25**, 636; 1971), he insists that their gait was always sprawling, and never even semi-erect; but, in 'Dinosaur Renaissance', even the earliest are said to have limb modifications which permitted trotting gaits. This leads to a further problem. In the earlier paper, Bakker argues that the 'fully erect gait' seen in dinosaurs is probably necessary for large endothermic tetrapods, because of the food-gathering requirements of endothermic physiology, and claims that the echidna *Zaglossus*, at 10 kg weight, "illustrates about the size limit possible for a homeothermic vertebrate with sprawling limbs." Large therapsids which he estimates at weights between 500-1500 kg in 'Dinosaur Renaissance' should hence have needed erect gaits as endotherms, if this argumen for dinosaurian endothermy is justified, but they cannot have had erect gaits if his analysis of limb movements is correct. In any case early forms seem unlikely to have had them.

The type of bone called 'endothermic' by Bakker is compact bone with a primary structure called fibro-lamellar by de Ricqlès (often, laminar bone *sensu* Currey), with more or less extensive Harversian substitution. This is now characteristic of large endotherms, and is seen by de Ricqlès (*op. cit.*) as reflecting their rapid initial growth rates, which in turn reflect high metabolic rates. A possible alternative correlation would be with size and gait only. It might, for instance, be claimed that bone formed from densely packed cylindrical primary osteons, with progressive Harversian remodelling as size and weight increase, is simply better adapted mechanically than lamellar-zonal ('ectothermic') bone as a structural material for the limb bones of large animals whose limbs support weight for long periods. It may even be needed for them to reach large sizes. This seems ruled out, however, as a primary correlation, if therapsid gaits are pictured conventionally, by the occurrence of this type of bone in early deinocephalians, and even the eotheriodont *Biarmosuchus*, but, ironically, this does not follow if even early forms possessed erect trotting gaits.

Treatment of therapsids as endotherms also weighs against this status for dinosaurs. Feduccia argued that impetus towards endothermy will have been greatest during periods of severe climate, and insufficient to lead to it in the times in which dinosaurs originated. Dodson's reply that "the ancestors of the dinosaurs lived at the same time and in the same place as the predecessors of the mammals" is valid if mammalian endothermy first arose in the immediate ancestors of the earliest 'true' (osteological) mammals. However, the precursors of the earliest therapsids were Lower Permian sphenacodonts. The earliest known thecodonts only date from the end of the Permian, long after large pareiasaurs had been able to enter southern Africa; dinosaurs did not appear until the Upper Triassic, when conditions presumably approached those of the Lower Jurassic optimum. Bakker claims Mesozoic climate as optimal at the end of the Jurassic, but marine invertebrates show minimal latitudinal zonation in Lias times, and a 'boreal' realm persisting from Bajocian times onwards.

It is not hard to find other minor inconsistencies. For instance, an estimated maximum sustained speed of 2.8 km h^{-1} for ostrich dinosaurs as ectotherms is contrasted with their having limbs like those of ostriches, which reach 50-80 km h^{-1} (*Nature*, 238, 81; 1972). Limb proportions however, are an index of speed, not endurance. In 'Dinosaur Renaissance', even early therapsids are supposed to have trotted, but examples (pristerognathids) are shown with semi-erect limbs, which would not permit trotting. Dinosaurs found within the Cretaceous Arctic circle in Canada are seen as suggesting the ability to tolerate cold, but large Cretaceous crocodiles from Saskatchewan are later pointed out as ectotherms. Such dinosaurs would also have needed to be migratory, unless able to feed in winter darkness. The predator–prey ratio for the early Cretaceous Cloverly Formation is based on the assumption that a 70 kg deinonychid preyed on two dinosaurs over 28 times heavier (2,000 kg) than itself, one of which was heavily armoured, and on a brachiosaur 571 times heavier (40,000 kg). This seems quite unlikely, unless it was simply a

0028–0836/78/0276–0757$01.00

scavenger, whereas, the specialised claws of *Deinonychus* suggest active predation on animals about its own size.

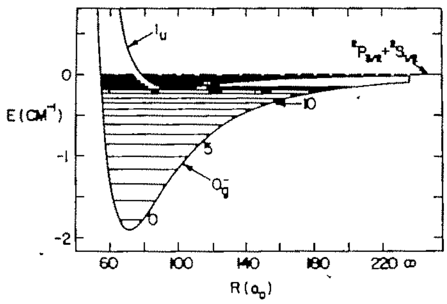
How do such problems affect the concept of dinosaur endothermy? They do not affect other arguments, such as Ostrom's contention that erect gaits may only be possible for endotherms, or Wheeler's recent comments (*Nature* **275**, 441; 1978) on cooling of the central nervous system. Erythrosuchids need not have been insulated, but did have whatever condition is responsible for 'endothermic' bone. The problem is that doubtful claims tend to discredit real evidence. But even so, if one follows Charig's rejection of predator–prey ratios, the only major line of evidence remaining is that from bone histology, which cannot be certainly attributed to endothermy rather than bulk.

I must also support Thulborn's view that small size, a naked skin, and endothermic physiology seems a lethal combination for hatchlings. This need not mean that dinosaurs were simply 'good reptiles', but their nearest possible approach to true endothermy, if their young lacked insulation, will have been some combination of fairly high metabolic rates with poikilothermy, (until temperature could be stabilised by bulk in the larger animals). Perhaps this type of physiology would be feasible for typically large animals, evolved in warm Middle to Upper Triassic conditions, but it does not correspond to the fully developed endothermy of mammals and birds, in which external insulation allows high stable temperatures to be maintained in small animals. ☐

Long-range molecules

from Graham Richards

Van der Waals forces are normally thought of as attractive. They are the weak attractions which hold molecules together with a binding energy often following the sixth power of the intermolecular separation. In fact this is only true for spherical charge distributions. Attractions of the c/r^6 form are appropriate for interactions between rare gas atoms but in more complicated instances this may not be true even between atoms. Perhaps most striking is the fact that if one of the atoms is in a spherically symmetrical S state and the other in an electronic state of P type then not only is the dispersion force of the form c/r^3 but it is repulsive!



The potential-energy curves for two long range states of Na_2.

This fact is utilised in a description of a new type of molecular electronic state by Stwally and Yea-Hwang Uang of the University of Iowa and Pichler of the Joint Institute for Laboratory Astrophysics in Boulder (*Phys. Rev. Lett.*, **141**, 1164; 1978).

The energy of a diatomic molecule is normally represented by a potential energy curve with a left-hand limit showing the vibrational turning point with the nuclei close together, and the right-hand branch the maximum stretch between the nuclei at the other extreme of vibration. Vibrational levels near dissociation give rise to 'long-range molecules' since although the molecule repeatedly vibrates classically from the inner turning point (typically 1 Å separation) to the outer one (typically 10–100 Å), it spends most of its time at the long range region.

The new type of pure long-range molecule is predicted to spend its entire time in long range regions with separations between 30 Å and 100 Å. These long-range molecules will be possible for electronic states where the repulsive van der Waals forces at large internuclear separations result in there being a small bump in the potential energy curve and a very small well in which vibrations can take place. The local energy minima at very long range arise from the recoupling of angular momenta.

In the familiar type of diatomic molecule potential curve the range of internuclear separation shown is perhaps 1–10 Å with the depth of the potential well being several electron volts (1 eV is approximately 8,000 cm^{-1} and 1,000 cm^{-1} is approximately 12 kJ mol^{-1}). This may be contrasted with the curves drawn in the figure.

Although typical in shape the depths of the potential well are now less than 2 cm^{-1} and average separation is over 30 Å (1 Bohr, $a_0 = 0.52917$ Å). The curves are those predicted by Stwalley *et al.* for two states of diatomic sodium.

Experimentally these states are visible as angular momentum recoupling extrema in the far wings of resonance lines of Rb and Cs. In particular, the red wing stellite on the 8521 Å line of Cs corresponds to the O^-_g state illustrated in the figure for Na_2. The authors hope to prepare molecular beams with significant populations of long-range levels of Li_2 and Na_2 and to observe rotational fine structure in bands involving the long-range states by laser spectroscopy. ☐

Metallic hydrogen

from N. E. Cusack

A recent report by P. S. Hawke and fellow workers at the Lawrence Livermore Laboratory (*Phys. Rev. Lett* **41**, 994; 1978) that highly compressed hydrogen is a metal raises again one of the most interesting questions in the physics of condensed matter, namely, what decides whether a substance is metallic or not? Many theoretical and experimental studies, going back to classical papers by Mott in the 1950s, have made it clear that one decisive parameter is the density In a way this is obvious; at room temperature liquid mercury, for example, is metallic but its vapour is not. But whether there is a critical density at which a sharp phase change from metal to non-metal occurs and, if so, what electronic mechanism is at work are still open to discussion and much depends on whether the material is crystalline, or structurally disordered as in a fluid.

For crystals, it holds that if the bands of allowed electron energy are either fully occupied or completely empty, then the material is non-metallic Partially empty bands permit metallic conductivity and therefore, if a full and an empty band can be made by a density change to overlap in energy, they will both become partially full and a metal will be created. The reverse could occur if the density change caused two overlapping energy bands to separate These are called 'band crossing transitions' and are believed to occur in insulating iodine and metallic ytterbium which, under high pressures, reverse their roles and become a metal and an insulator, respectively However, other considerations enter for monovalent metals like sodium which have half full energy bands. If these could be reduced in density—not possible in the crystallised state—it is thought that at a critical density the electrons would condense on to the ions and be bound into neutral centres thus losing their freedom to conduct electricity. Contrary to the band crossing case, such a transition is chiefly an effect of the mutual interactions of the electrons themselves and is known as a Mott transition. There are theoretical reasons for believing that both Mott and band crossing transitions are discontinuous phase changes in crystals.

In fluids, or disordered solids, the whole matter is complicated by the structural chaos and although discontinuous transitions are not ruled out, gradual changes are quite possible. Furthermore, electrons may lose their ability to conduct electricity because the disorder itself confines them to finite regions of the material—an unexpected and subtle modification of the electron wave functions known as 'Anderson localisation'. Fluid mercury reduced in density to about $9\ \mathrm{g\ cm^{-3}}$ at about 1400 °C and 1500 bar pressure is believed to become non-metallic by a continuous process involving Anderson localisation.

In all this, the behaviour of hydrogen is particularly challenging for a number of reasons. In the first place, increasing the density of hydrogen sufficiently to give it any chance of becoming metallic requires enormously high pressures—in the megabar range. If the production of such high pressures is accompanied by high temperatures, knowledge of the sample density, or even of whether the hydrogen is liquid or crystalline, will require some understanding of the equation of state. Understanding of both the equation of state and the metal–non-metal transition ought to come relatively easily with hydrogen because it is the simplest element. However, solid hydrogen is a molecular solid and from the point of view of the electron energy band theory has full and empty bands and is therefore an insulator. If it is sufficiently compressed will it undergo a band crossing transition or will it suddenly transform to a monovalent metal with half full bands like the next simplest monovalent metals lithium and sodium? These questions have an interest beyond solid state physics because high pressure hydrogen exists in the larger planets of the Solar System, and planetary magnetic and other properties will be greatly influenced by whether their hydrogen layers are metallic or not.

In their paper, Hawke and collaborators reported high conductivity in a hydrogen sample at a density of $1.06\ \mathrm{g\ cm^{-3}}$ and a pressure of 2 Mbar. The detection of metallic hydrogen had been reported previously at about 2.8 Mbar by Grigor'ev *et al.* (*JETP Lett.* **16,** 201; 1972) but by interpreting an 'anomaly' in the thermodynamic properties rather than by observing high conductivity. These two groups attain the high pressure by causing an explosive to implode a cylindrical container. In the Livermore experiment the imploding steel cylinder compresses magnetic flux which in turn compresses the hydrogen sample inside its silver holder. In such experiments measurements must be carried out by rapid methods during the 10 or 50 microseconds available. Densities, for example, are found by observing the sample volume by X-ray flash radiographs, and conductivities by operating continuously a reflectometer using 15 MHz pulse trains. Other investigations of high pressure hydrogen have tried shock waves and high intensity laser pulses to produce the pressure. It is not impossible to get into the megabar range with static anvil devices and indeed Vereshchagin *et al.* (*JETP Lett.* **21,** 85; 1975) claimed in 1975 to have detected metallic hydrogen at 1 Mbar in such a static equipment with the sample at 4.2 K.

There seems little residual doubt that metallic hydrogen can be made and that it needs a small number of megabars to do it. Theoretical estimates of the transition pressure have ranged in the past from about 1 to 20 Mbar and it is of course no easy matter to calculate it. The theoretical approach is to calculate the energies of the atomic metallic and molecular insulating phases separately using solid state methods and then determine the pressure and density at which the free energies of the two phases are equal. One recent calculation (Ramaker *et al. Phys. Rev. Lett.* **34,** 812; 1975) gave 2.1 Mbar which suggests that theory and experiment are beginning to converge. Hawke *et al.* do not consider that a band crossing transition in the molecular crystal has been ruled out by their work but that an abrupt transition to an atomic phase comparable with metallic sodium is at present favoured.

The interest of this work to physicists of condensed matter is considerable and is enhanced both by a suggestion of Ashcroft's (*Phys. Rev. Lett.* **21,** 1748; 1968) that metastable metallic hydrogen (if it exists) might be superconducting at room temperature, and also by the relevance of compressed hydrogen isotopes to nuclear fusion. A growing understanding of this interesting example of a metal–non metal transition can be confidently expected but experiments and theory are both difficult and progress may not be rapid. ☐

The cladistic revolution—can it make the grade?

from L. B. Halstead

OVER a decade ago a German entomologist, W. Hennig, published his book *Phylogenetic Sytematics* (University of Illinois Press, Urbana, 1966) in which he presented a codified methology for determining the relationships of organisms. As the entire system was designed in such a way that fossils could hardly be included, little serious note was taken of the phenomenon which has become known as cladism. Palaeontologists did not reckon on the ingenuity of certain colleagues, who not only succeeded in applying it to fossil fishes, but managed to convert others to this new system.

It was with this background in mind that a special session was set aside for the topic to be debated at the 26th Symposium of Vertebrate Palaeontology and Comparative Anatomy held in September at the University of Reading.

P. Forey, British Museum (Natural History), outlined the methods and aims of the cladists. Hennig had stressed that it was necessary to distinguish primitive or original characters, which he termed plesiomorphic, from advanced or derived ones, now named apomorphic, in order to ascertain the direction in which evolution had progressed. If a number of lineages can be united on their primitive or plesiomorphic characters the grouping is termed paraphyletic and as such is rejected in the Hennigian scheme, since only strictly monophyletic lineages are recognised. Groups that are united on shared derived characters, or a synapomorphy, can, however, be placed in a valid taxon. The approach of the followers of Hennig is best seen in their construction of cladograms, a system of repeated dichotomies where at each branching a new monophyletic lineage is distinguished by a change in at least one derived character state from the original condition. It is axiomatic that such sister groups are given identical rank. Hence an adjacent lineage and all those subsequently descended from it will have the same taxonomic rank as the preceding lineage. Furthermore there is no place for ancestral species in a cladogram. Where complete sequences from species to species or, as G. MacIntyre (Queen's College, New York) demonstrated, from genus

---

L. B. Halstead is Reader in Geology and Zoology at Reading University and Research Fellow at the Royal Dental Hospital of London.

to genus can be demonstrated, then since they will represent a monophyletic lineage, they must necessarily be included in a single specific taxon.

In order to construct a cladogram it is necessary first to be able to distinguish between original and derived characters and to assemble them in some kind of hierarchy, which as S. Westoll (University of Newcastle) stressed, involved a degree of subjectivity from the very outset.

A cladogram is essentially an hypothesis and its validity is continually tested by the law of parsimony (that no more causes or forces should be assumed than are necessary to account for the facts). An example of this process was illustrated by cladograms presented by P. Janvier (University of Paris) on agnathans and B. Gardiner (Queen Elizabeth College, London) on choanichthyans both of which were demolished within hours of their being proposed. One of the problems of cladism is that fossils can only be considered once the model for their modern representatives had been worked out — a very difficult situation for groups with no agreed living representatives such as heterostracan agnathans and dinosaurs.

Cladism has been extensively applied to insects and the symposium volume edited by Greenwood, Miles and Patterson (*The Interrelationships of fishes*, Academic Press, London, 1973) ranks as a major monument to the application of Hennigian principles to the study of fish.

In contrast the very concept of structural grades is anathema to all cladists Bonde (*Colloque internat. CNRS* No. 218, 293; 1975) claimed "very little has been achieved in studies of other vertebrate groups, for example by Romer (1966, 1968) and Halstead (1969) where grade classification and paraphyletic groups are repeatedly recommended because of the enormous influence of Simpsonian philosophy." Yet as all teachers and writers concerned with the study of the history of life on this planet well recognise, major evolutionary events can be best understood in terms of major structural grades, which happen to coincide with the major classes of the vertebrates. The idea of separate evolutionary lineages achieving a higher grade of organisation, say from a reptilian to a mammalian grade, should occasion no surprise. In terms of understanding evolution, the fact that many parallel changes can be related to adaptations to similar conditions, is more significant than listing trivial trademarks from which cladograms can be constructed. The aim of the cladists is simply to delineate relationships and to insist on a classification that reflects this in its entirety at the expense of all other considerations.

Yet if it were possible to trace the ancestry of man back in time to a rhipidistian fish then the entire sequence of stages would be by definition a single monophyletic species. This must surely have happened, yet most zoologists and palaeontologists would surely accept the reasonableness of dividing such a lineage into a number of arbitrary divisions. Commonsense alone would dictate such a course of action. Even though it is possible to take all the end twigs of the evolutionary tree that exist at the present time and construct a hypothetical tree of them, such sharp distinctions must of necessity vanish as they are traced back in time Evolution is a gradual process that takes place through time and man simply imposes on it his own arbitrary system of classification.

The issue was summed up for many by R. Parrington's (University of Cambridge) exasperated exclamation that according to the cladists a lungfish is more closely related to a cow than to a salmon to which C. Patterson (British Museum (Natural History)) answered "Yes, I cannot see what is wrong in that".

The cladists adhere to the tenets of Hennigism with religious fervour and are already entrenched in some of the major museums in the world. The new evolution and diversity exhibit in the Natural History Museum is destined to be organised to show relationships. If the familiar arrangement of family trees illustrating not only relationships but also their distribution through geological time were to be replaced by elaborate cladograms, I feel it would be a severe error of judgement Cladograms are difficult enough for experts in the field to comprehend fully, let alone the casual visitor seeking either knowledge or entertainment. ☐

Earthquakes and fault gouge

from Peter J. Smith

MANY large shallow earthquakes are evidently associated with slip along pre-existing faults in the Earth's crust But this is not to say that the shallow-earthquake mechanism is anything like fully understood; on the contrary, there are outstanding problems of a quite fundamental nature. For example, laboratory experiments on the frictional sliding of rock carried out during the late 1960s suggested that the shear stress needed to activate rock-on-rock sliding was an order of magnitude higher than that actually present on the San Andreas fault, the latter being deduced from local heat flow studies In other words, stick-slip seemed the most likely mechanism for shallow earthquakes, but it was by no means clear that, in the San Andreas fault zone at least, the conditions for it actually obtained.

More recently the stress criterion has been relaxed insofar as Hanks (*Pageoph.* **115**, 551; 1977) and others have argued for a real stress along the fault rather higher than that previously supposed. Even so, it still seems worthwhile to consider what, if anything, could reduce the shear stress actually required to produce fault slip. An obvious possibility here is the presence of fault gouge, for repeated movements in the highly fractured San Andreas fault zone are likely to have led to extensive comminution, and the resulting gouge may even have been altered by hydrothermal fluids Presumably, therefore, this gouge, altered or not and dry or wet, could modify the San Andreas fault's slip behaviour Indeed, some very recent laboratory experiments (for example, Summers & Byerlee, *Int. J. Rock Mech. Min. Sci.* **14**, 155; 1977) have shown that artificial gouge between cut rock surfaces often reduces the coefficient of friction, which makes it all the more surprising that gouge—a long-known substance, after all—has not hitherto played a much greater part in mechanism studies. Yet as Wang *et al.* point out (*Geophys Res. Lett.* **5**, 741; 1978), "Experimental data on gouge under conditions appropriate for upper and mid-crustal environments are still lacking".

But first, does fault gouge actually exist in appreciable quantity at depth in the San Andreas fault zone? Intensely faulted and severely altered rocks combined with clay minerals are certainly present at the surface, even though the lack of detailed mapping and classification makes it difficult to obtain 'representative' samples Nevertheless, Wang and his colleagues have collected fault gouge from outcrops along both the San Andreas and Hayward faults and, for reason that will soon become clear, have measured P and S seismic wave velocities in them at various confining pressures up to

Sicily: the world reservoir for thalassemias and haemoglobinopathies

from Gino Schilirò

SICILY is particularly affected by the hereditary disorders of haemoglobin synthesis (the thalassemias and haemoglobinopathies) that are found all around the Mediterranean. In Sicily the very common β-thalassemias and the many haemoglobinopathies present a serious public health problem. For this reason a Centre for the study and treatment of thalassemias was established in Catania in 1965. This Centre, under the direction of Professor Giuseppe Russo, staffed by physicians, laboratory technicians and nurses, serves not only as a modern treatment facility and follow-up for 250 children with Cooley's anaemia (thalassemia major) but also as a centre of research into thalassemia and of a public education campaign[1]. Mass screening to detect thalassemia carriers and those with other haemoglobinopathies, and preventive genetic counselling is an important element of the programme of the Centre. Since the estimated number of Sicilian newborns with Cooley's anaemia is about 105 each year, we are developing a programme for prenatal diagnosis.

From 1974 to November 1978, 7,143 subjects with suspected hereditary haematological disorders were examined at the Centre: 28.5% of them were carriers of haemoglobin anomalies; 292 were homozygous β-thalassemia, 1,342 β-thalassemia trait and four homozygous $\delta\beta$-thalassemia. We also found 40 cases of α-thalassemia as α_1, α_2 and HbH disease, but no cases of hydrops fetalis have been seen. The exceptionally high incidence of the haemoglobinopathies in Sicily is reported in Table 1. The interaction between the thalassemias, with their genetic heterogeneity, and the haemoglobinopathies gives extremely interesting haematological pictures[2]. If one considers that several abnormal haemoglobins have also been reported by others[3] in Sicilians or people of Sicilian ancestry, then it is evident that Sicily, because of its geographical position and history, is a place of unique genetic admixture.

In studies of globin synthesis in randomly chosen patients with Cooley's anaemia, two groups have been distinguished: β^0-thalassemia (30%) characterised by the absence of β chains, and β^+-thalassemia (70%) with low levels of β chain synthesis[4]. In collaboration with other Italian and foreign laboratories, research at the Centre has contributed to the clarification of some of the molecular defects of the thalassemias. $\delta\beta$-Thalassemia has been found to be caused by a genetic delection[5]. We have also observed that while β globin synthesis is completely absent in cells of patients with β^0 Catania, there is β-globin mRNA in the cytoplasm of the cells of these patients and that the β^0 patients seem to have the normal number of β-globin genes[6].

Haemoglobin S is the most common abnormal haemoglobin found in Sicily. The mean frequency is 1% although in certain areas it may reach 14%, as in people of African origin. The chemical and physical identity of Hb S in both USA Blacks and Sicilians as well as the presence of African blood group markers suggest that Hb S may have spread from Africa to Sicily[7]. Another haemoglobin we have found is Hb C, of known African origin. Among the 18 families with Hb J Oxford reported in the literature, 13 are Sicilian or of Sicilian ancestry. Carriers of this haemoglobin are asymptomatic and discovered only by screening. It should be noted that in all our cases the rate of Hb J Oxford was about 25%, supporting the hypothesis that α chain production is controlled by four genes. A case of interaction between homozygous β^0-thalassemia and Hb J Oxford, producing a new alkali-resistant haemoglobin $\alpha_2{}^J\ \gamma_2{}^F$, is an example of the wide range of possible genetic combinations in this island with so many disorders of haemoglobin synthesis[8].

Although these data come from a selected population at risk, the phenomenon still remains extremely important. In fact, since 1893 many people have emigrated from Sicily to North and South America, to Australia and, more recently, to North Europe. Especially if one considers that, in the 20 years between 1951-71, 1,010,963 Sicilians emigrated, the Sicilian haemoglobin abnormalities become of general interest.

G. Schilirò is in the Department of Pediatrics, at the University of Catania, Italy.

Abnormal haemoglobins found among 7,143 blood specimens

Genotype	Number	Structural* alteration	Genetic combinations found (number of cases)
Hb S	277	β^6 Glu → Val	S–S(8) S–A(194) S–β^0Th(30) S–β^+Th(55)

2 kbar (equivalent to a depth in the Earth of 8-10 km).

The results are simply stated. The P wave velocities in the fault gouge samples and their variation with pressure (depth) are very similar to those obtained by Healey and Peake (*Bull. Seismol. Soc. Amer.* **65**, 1177; 1975) for the central Californian region of the crust bounded by the San Andreas and the San Benito faults. Moreover, both the P and S wave velocities in the gouge and the P wave velocities obtained by Healey and Peake are significantly lower than those in intact rocks, whether the intact rocks be *in situ* crust in the region outside the San Andreas fault zone or samples brought from the San Andreas fault zone itself (Lin, thesis, University of California, 1977). In other words, the low seismic velocities in the San Andreas fault zone are consistent with the presence of appreciable amounts of gouge to depths

0028-0836/78/0276—0761$01.00

of at least 8-10 km. Support for this interpretation also comes from gravity data, for to explain the steep gradient in the Bouguer gravity profile near the San Andreas fault zone it is apparently necessary to invoke the presence of a slab of low density (~2.6 g cm^{-3}) extending to a depth of 8-10 km. A density of 2.6 g cm^{-3} is typical of fault gouge.

Wang and his coworkers go no further with their experiments; but they have gone far enough to show that fault gouge as a possible modifier must not be ignored when it comes to considering the causes of shallow earthquakes. □

Phase transitions in spin glasses

from a Correspondent

IF the temperature of a supercooled liquid is lowered sufficiently, it may form a glass. For twenty years or more there has been an inconclusive debate as to whether this change is of purely kinetic origin, occurring when the relaxation times of the liquid become longer than the patience of the experimenter, whereupon the liquid appears to have solid properties, or whether the change reflects an underlying phase transition. It looks as though the debate on the causes of the similar phenomena found in spin glasses may be just as lengthy and inconclusive.

A spin glass is typically a substitutional alloy of a few percentage of a transition metal such as iron or manganese in a host metal such as copper or gold. The transition metal impurities—the spins of the spin glass—can be taken as being approximately randomly distributed throughout the alloy. They interact with each other through the conduction electrons of the host metal to give a long-range coupling between the spins whose sign depends on the distance between the spins. This means that the interaction between some spins is ferromagnetic in sign which favours their parallel alignment while that between other pairs of spins is antiferromagnetic which favours their antiparallel alignment. The net effect of such a mixture of competing interactions is to produce a ground state in which the orientation of the spins is chaotic and which has no resultant magnetic moment.

When cooled below its freezing temperature T_F, the properties of a spin glass are radically altered in much the same way as the properties of a supercooled liquid are altered below the glass transition temperature T_g. Above T_F an induced magnetic moment rapidly decays away on a microscopic time scale when the magnetic field which induced it is switched off. Below T_F an induced moment can take hours to decay away. One can immediately deduce that some relaxation processes in a spin glass take place very slowly. Another characteristic is the 'cusp' in the magnetic susceptibility at the freezing temperature. The susceptibility as a function of temperature rises at T_F to a maximum which is quite sharp, especially when the susceptibility is measured using small applied fields.

Non-analytic behaviour such as a cusp usually indicates that a phase transition must be taking place. In 1975, Edwards and Anderson (*J. Phys.* **F6**, 1927; 1975) proposed a phase transition theory for spin glasses which gave a seemingly satisfactory explanation of the cusp. The order parameter q of their theory is the probability that any given spin is still pointing after an infinitely long time in the same direction as it was at some initial time. Above T_F, q is zero, but below T_F, which is identified as the phase transition temperature, it is non-zero and increases to unity as the temperature approaches absolute zero.

Although we live in a three-dimensional world, it is both interesting and useful to examine (theoretically!) the nature of a phase transition in worlds of different dimensionality. There is always a 'lower critical dimension' below which the phase transition will not take place. Thus the Heisenberg type of ferromagnet does not have a phase transition in two dimensions for its lower critical dimension is two. The lower critical dimension for the spin glass transition is controversial, with arguments being advanced for two, three and four dimensions. Numerical evidence derived from high-temperature series expansions seems to favour four (Reed, *Phys. Lett.* **A68**, 473; 1978). If that really is the case, then the phase transition theory of spin glass behaviour fails and an alternate explanation must be sought.

An explanation which actually predates the phase transition theory is that spin glass behaviour is entirely a non-equilibrium effect resulting from the long relaxation times which exist within spin glasses at low temperatures. The relaxation modes probably involve activation processes in which a potential barrier separating two easy orientations of a spin has to be surmounted. This will produce relaxation times which follow an Arrhenius law and so rapidly increase at low temperatures. The 'cusp' in the susceptibility is explained on this hypothesis by observing that at temperatures below T_F only a fraction of the total spins present will contribute to the susceptibility, namely those spins or groups of spins which can relax on a time scale shorter than the time scale of the experiment. The other spins are effectively frozen in fixed orientations and do not contribute. For a given experimental time scale, the further the temperature is lowered below T_F the larger the fraction of frozen spins becomes and hence the smaller will be the observed susceptibility. A corollary of this hypothesis is that the freezing temperature T_F should alter with the experimental time scale. Lengthening the time scale should enable more spins to contribute to the susceptibility and so depress the apparent freezing temperature. A similar effect occurs at the glass transition in ordinary glasses where T_g falls when the liquid is allowed a longer time to come to equilibrium.

A recent experiment of Murani and Heidmann (*Phys. Rev. Lett.* **41**, 1402; 1978) clearly indicates that lengthening the time scale depresses T_F. They have carried out neutron inelastic scattering measurements on a Cu–8 at % Mn alloy at three different energy resolutions. The temperature dependence of the elastic magnetic cross section can be extracted from the data. It is related to the Edwards-Anderson order parameter q on a phase transition hypothesis and to the number of frozen spins on a relaxation time hypothesis. The elastic cross section increases below a certain temperature but the temperature at which this happens, the nominal freezing temperature, varies with the energy resolution employed. They argue that the time scale in their experiment is proportional to the inverse of the energy resolution. For a time scale of 10^{-11} s, T_F is 75 K, whereas T_F is about 40 K on a time scale of 10^{-2} s (this latter data is from separate experiments on the a.c. susceptibility). At first sight this appears to be strong evidence against a phase transition (since a phase transition should take place at a unique temperature) and in good accord with the explanation of spin glass behaviour in terms of long relaxation times and frozen out spins.

Unfortunately it is not as simple as this. A phase transition could be accompanied by long relaxation times which would produce an apparent freezing temperature that decreased with increasing experimental time scale, but which eventually saturates at the true transition temperature T_F for a hypothetical experiment with an infinitely long time scale. There is just a hint of such a possibility within their data but it is not sufficiently strong to be compelling evidence. It is clearly going to be very difficult to decide from experiments of this kind whether spin glass behaviour is or is not due to a phase transition. A new idea is needed for a conclusive experimental test to distinguish the rival approaches.

review article

Electron cooling and its applications in elementary particle physics

N. S. Dikansky, I. N. Meshkov & A. N. Skrinsky

Institute of Nuclear Physics, Siberian Branch, Academy of Sciences of the USSR, Novosibirsk 90, USSR

In recent years, experiments in high-energy physics have shown that one of the most promising means of studying the properties of elementary particles is by colliding beams. First, they open up a region of interaction energies at present unattainable using conventional accelerators. Second, they allow experiments to be performed in extremely clean conditions, when the observed interaction between two colliding particles is not contaminated by the presence of secondary interactions as in the conventional particle accelerator–fixed target scheme. This article describes the electron cooling method applied to proton–antiproton colliding beams.

THE first experiments carried out with electron–electron colliding beams in 1965 at Stanford and Novosibirsk gave a convincing demonstration of the potential of this technique in high-energy physics. In these experiments, from practical considerations, electrons were preferred, however, to obtain more information on elementary particles, colliding beams of particles and an anti-particles are of much greater interest. In the interaction between a particle and an anti-particle, a state is produced in which the total charges of all kinds, such as electrical, lepton, and baryon, equal zero, and the system is then released from the conditions imposed by the conservation laws of these charges. In fact, this state is equivalent to a pure energy-blob, capable of creating any particle–antiparticle pairs permitted by the energy-momentum conservation law. The first experiments on colliding beams with particle–antiparticle (electron–positron) annihilation were carried out at the Nuclear Physics Institute in Novosibirsk on the VEPP-2 apparatus (abbreviations of Vstrechnye Elektron-Pozitronnye Puchki—electron–positron colliding beams). The energy of the particles in these experiments reached 0.67 GeV. There are six electron–positron colliding-beam devices at various accelerator centres throughout the world (Novosibirsk, Stanford, Orsay, Hamburg, Frascati), with energy ranges from 2×0.2 to 2×4 GeV. Three more electron–positron colliding beam machines are under construction (Novosibirsk, Hamburg and Stanford) with an energy range of 2×4 to 2×20 GeV.

Experimental constraints

Electrons and their antiparticles are interesting as they represent 'point' objects: according to current experimental data the size of these particles does not exceed 10^{-15} cm. Unfortunately, for electrons and positrons the practical energy limit for colliding beams in their traditional configuration is not very far from the level attained today. This limit is associated with synchrotron radiation, the intensity of which increases as the fourth power of the energy of the particle, and decreases only as the first power of the orbit radius, so that increasing the size of the ring provides no real solution to the problem. Colliding beams of heavy particles do not have this problem as the intensity of synchrotron radiation is inversely proportional to the fourth power of the rest mass of the particle. But here, unhampered by energy losses, we have at the same time lost a mechanism which quenches the oscillations of the particles in the storage ring and so permits multiple storage of particles in the same phase volume.

For proton–proton colliding beams this does not in principle create any constraints as there are ways of producing intense beams of protons. The first proton intersecting storage rings have been in operation at CERN since 1971. However, for antiparticle beams accumulation is essential because of the low production yield. Antiparticles are generated with a large phase volume and it is therefore important to incorporate a mechanism for reducing the phase volume of the beam.

Such a mechanism was found by Budker, for heavy particles, who proposed the electron cooling method. Subsequently, it was realised that this method permits the accumulation of large antiproton currents and allows experiments to be carried out on proton–antiproton ($p\bar{p}$) collisions (A. Skrinsky). Hence, in 1966 at the Paris conference on colliding beams[1], in addition to the electron cooling method, Budker presented a $p\bar{p}$ colliding beam project worked out at our Institute. Although both the electron cooling method and the $p\bar{p}$-colliding beam project evoked great interest little progress was made, for the following reasons. First, the electron cooling method had not been demonstrated experimentally. It seemed to be an exotic idea with little hope of realisation. Second, during the 1960s, experiments on $p\bar{p}$ colliding beams were considered an important but extremely complicated way of supplementing $p\bar{p}$ experiments studying the nature of strong interactions.

Today the situation has changed radically. The observation of point-like constituents in protons which are now identified with quarks, has forced us to reconsider our attitudes to $p\bar{p}$ colliding beams: from the point of view of the quark model of strongly interacting particles, such beams are equivalent to colliding

0028–0836/78/0276—0763$01.00

beams of quarks and antiquarks. This implies that $p\bar{p}$ colliding beams provide fundamental information similar to that obtained from electron–positron (e^-e^+) colliding beams. During the interactions, energy is liberated 'at a point' that is it is not smeared over an extended object; which allows information to be obtained on the properties of matter at limitingly small distances. According to current ideas, the proton (antiproton) contains three quarks, so that $p\bar{p}$-colliding beams with a given energy are equivalent to e^-e^+ colliding beams with energy three times less.

Finally, during the past few years, a decisive step forward has been made towards the creation of $p\bar{p}$-colliding beams: the electron cooling method has been studied and developed experimentally. This article describes this method and its potential for elementary particle and nuclear physics.

Machine luminosity

The efficiency of a colliding beam machine is characterised by the luminosity L, a quantity equal to the number of interactions per unit time during the collision of two beams per unit interaction cross-section. Then the counting rate in the i-th reaction channel with cross-section σ_i is

$$\frac{dN_i}{dt} = L\sigma_i \tag{1}$$

In the case of two bunches with N_+ and N_- colliding particles the luminosity is given by the relationship

$$L = \frac{N_+N_-}{S} f \tag{2}$$

where f is the frequency of revolution of the particles in the ring, and S is the cross-section of the larger of the bunches. The fundamental problem with colliding beams is to obtain the maximum possible luminosity. We note that equation (2) holds if the detector sees the whole intersecting region. Hence it is advantageous to work with beams of short bunches.

When working with antiparticle beams the problem of intensity is especially serious. Antiparticles are produced by accelerators in comparatively small quantities, being ejected from a target by a beam of particles of sufficiently high energy. Moreover only a small fraction of the antiparticles thus generated can be injected into the storage ring: the permissible energy spread in a beam of anti-particles is usually a fraction of a per cent of the mean energy of the injected particles. For example, in the VEPP-2M storage ring out of 10^{11} electrons it was possible to obtain only of the order of 10^7 useful positrons, while for experiments with colliding beams it is necessary to have at least 10^{10}–10^{11} particles. Thus the only course is the accumulation of antiparticles: by multiple injection into the same phase volume of the storage ring. For this, it is necessary to constrict the phase volume of the injected beam before the next injected pulse, thus releasing phase space for the next lot of particles. This increase in the density of the beam in phase space takes place if friction is introduced into the system of particles.

Particle oscillations

A particle orbiting in a storage ring is known to perform oscillations in the focusing fields of the ring magnets with respect to some equilibrium trajectory. Three-dimensional oscillations in the (x, y, z) coordinate space correspond to motion over the surface of a six-dimensional ellipsoid in the coordinate-momentum (p_x, p_y, p_z, x, y, z) phase space. The set of N particles occupies some volume in phase space which remains invariant with time if the oscillations are not damped. If, however, a frictional force acts on the particles, the amplitude of their oscillations decreases with time, and, consequently, the volume which they occupy decreases.

If the frictional force $\mathbf{F}$ is proportional to the total velocity $\mathbf{V}$ of the particle

$$\mathbf{F} = -\lambda m \mathbf{V} \tag{3}$$

the decrease of the amplitude (A) of oscillations in the case of weak friction is exponential ($\lambda \ll \omega$), where m and ω are the mass and frequency of the oscillations of the particle, with a decrement

$$\lambda = \frac{-1}{A}\frac{dA}{dt} \tag{4}$$

In addition to friction, diffusion processes are always present in a real system, the action of these may be characterised by the diffusion coefficient D:

$$\frac{da^2}{dt} = D \tag{5}$$

Then the damping of the oscillations and the constriction of the phase volume reaches some steady equilibrium value when friction and diffusion are equal:

$$a_e^2 = \frac{2D}{\lambda} \tag{6}$$

These equations define two important characteristics of the storage ring: the rate of compression of the phase volume λ and the minimum (steady) dimension a_e of the stored beam, on which the luminosity of the storage ring depends.

Radiation friction

An example of such a dissipative process is the radiation friction for electrons and positrons due to synchrotron radiation which we have already mentioned. The force of reaction of the radiation is directed opposite to the total velocity of the particle. If the accelerating system of the storage ring keeps the longitudinal component of momentum constant on average, then the radiation friction quenches the deviations of the momentum from the equilibrium value. Radiation friction is a powerful dissipative process: typical damping times of the electron and positron oscillations in operational accelerators are from 1 s down to milliseconds. This allows the problem of multiple stacking to be solved. Hence electron–positron colliding beams have high luminosities. This mechanism, as noted above, does not apply to heavy particles—protons, antiprotons or ions.

Electron friction

In Budker's method, the friction in a beam of heavy particles circulating in a storage ring is introduced by the flow of electrons. For this, it is necessary to arrange in the straight section of the trajectory of the heavy particles, their interaction with electrons of the same mean velocity as the heavy particles. A particle whose velocity differs from the mean experiences, as a result of collisions with the electrons, the action of a frictional force which tends to damp its oscillations. In the simplest case of homogeneous electron beam with maxwellian velocity distribution the damping for each of the three spatial degrees of freedom is identical:

$$\tau = \frac{1}{\lambda} \approx \frac{0.5}{r_e r_p c L}\frac{\gamma^2}{n_e \eta}\left[\left(\frac{T_e}{mc^2}\right)^{3/2} + \left(\frac{T_p}{Mc^2}\right)^{3/2}\right] \tag{7}$$

Here r_e, r_p are the classical radii of the electron and the heavy particle, m, M, T_e, T_p are their masses and temperatures, n_e is the electron density in the cooling current, $\gamma = (1-\beta^2)^{-1/2}$ is the relativistic factor, β is the mean velocity of the particles in units of the velocity of light c and η is the fraction of the perimeter of the orbit occupied by the cooling section.

This model is equivalent to a homogeneous two-component plasma (particles–electrons), while equation (7) is the relaxation time of the plasma (equalisation time of the temperature of both components). To find the steady amplitudes of oscillations, equation (6), in this simple case there is no need to calculate the diffusion coefficient for a heavy particle in the electron gas: it is clear that the steady state corresponds to the equilibrium temperature of both components:

$$T_p \simeq T_e, \text{ or } V_p = \left(\frac{m}{M}\right)^{1/2} V_e \qquad (8)$$

Thus if the temperature of the cooling electrons is low ($T_e \ll T_p$), electron cooling works effectively. (All units are given in the centre mass rest frame.)

Naturally, the kinematics of a real cooling process are more complicated. The detailed motion of the proton beam in the storage ring must be taken into account, and also the effect of errors in the equalisation of the mean velocities of electrons and protons, coherent fluctuations of the electron beam, and so on.

Electron beam cooling

In the experiments described below, various effects associated with special features of the electron beam have been studied: the role of the sharp anisotropy of the velocity distribution function of the electrons in a beam accelerated by an electrostatic field[2], and the effect of a strong magnetic field on the cooling efficiency[4]. Fortunately, the latter effects increase the cooling properties of the electron beam. Today the process of electron cooling is fairly well understood and has been studied extensively.

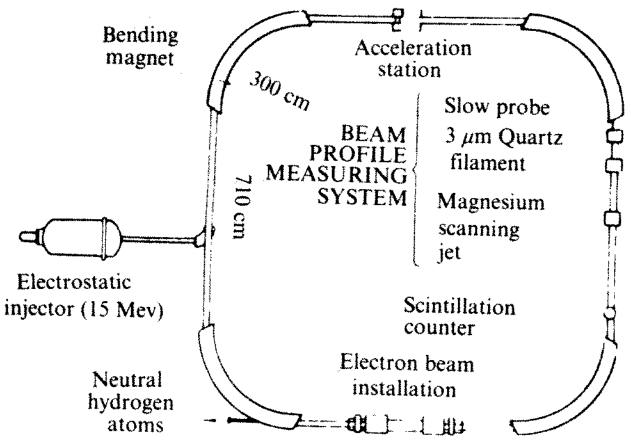

Fig. 1 Layout of the NAP-M proton accelerator.

The practical realisation of this technique started at the Nuclear Physics Institute in 1967. In 1974, the first experimental results on the electron cooling of protons were obtained, confirming that the fundamental ideas were correct (G. I. Budker, Ya. S Derbenev, N. S. Dukansky, I. N. Meshkov, V. V. Parkhomchuk, D. V. Pestrikov, R. A. Salimov, A. N. Skrinsky, B. N. Sukhina), while further studies of the technique by the same group indicated its high efficiency.

The experiments were carried out using a facility called the NAP-M (NAP is nakopitel antoprotonov—antiproton storage ring; M = model). The apparatus is shown in Fig. 1. Its perimeter is 47m and the length of each of the four straight sections is 7.2 m. The mean pressure of the residual gas in the vacuum chamber of NAP-M with the electron beam is $< 5 \times 10^{-10}$ torr. The stability of the magnetic field of the storage ring in the electron cooling regime is better than 1×10^{-5}. The control of the ring and the analysis of the experimental data was carried out by an on-line computer.

The electron beam for the cooling process comes from a source in the straight section of the storage ring (Fig. 2). The effective length of the cooling section is only 1/50 of the perimeter ($l = 1$ m, $\eta = 2 \times 10^{-2}$). An intense electron beam with low transverse velocities is obtained from a special electron gun, it is then guided in a longitudinal homogeneous magnetic field of 1 kG which extends up to the collector. The electron energy is recovered in the apparatus; this is especially important for high-energy electron-cooling devices.

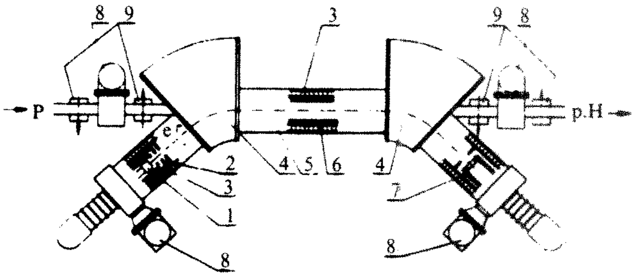

Fig. 2 Layout of an electron-beam installation: 1, electron gun; 2, anodes; 3, solenoid; 4, bending section of electron beam; 5, cooling section; 6, vacuum chamber; 7, collector; 8, vacuum pumps; 9, correction magnets.

The effect of electron cooling may be observed immediately, using a thin (0.5 mm) jet of magnesium vapour to measure the density of the proton beam. The jet intersects the proton beam, and the secondary electrons are collected by the electrostatic field onto a scintillation screen and recorded by a photomultiplier. When the jet scans the storage ring aperture, the transverse density distribution of the proton beam can be reproduced on an oscilloscope screen.

Without the electron beam, an increase in the dimension of the proton beam is observed due to multiple scattering on the residual gas. After the electron beam is switched in, the dimension of the proton beam decreases sharply. The effect of damping is seen especially clearly if the jet is kept at the centre of the damped proton beam and its dimension is increased by means of an inflector pulse. Then the density at the centre of the proton beam which is reduced after the pulse will increase to its equilibrium value within a characteristic time, τ.

The steady dimension of the proton beam is especially easy to measure with high accuracy by observing the beam of fast hydrogen atoms which is created in the cooling section as a result of the recombination of protons with the cooling electrons. It is interesting that even without special efforts more than 10% of the protons are converted into fast neutral atoms during the lifetime of the beam. At a distance of 10 m from the cooling section the dimension of the neutral beam is only 0.7 mm.

The damping of the energy spread of the proton beam is well demonstrated when the RF system of the storage ring is disconnected. If the energy of the electron beam is varied slightly, then the energy of the proton beam also varies and the radius of the proton orbit changes accordingly. If the energy of the electron beam and the magnetic field of the storage ring are varied simultaneously, then the proton beam can be accelerated or retarded without changing the equilibrium position of the orbit. Thus, for example, a proton beam was accelerated from 65 to 85 MeV during 200 s, corresponding to an energy gain by the protons of 0.3 eV per revolution.

Electron cooling was successfully verified in the proton energy range from 1.5 MeV (injection energy) to 85 MeV (0.4 GeV/c momentum) both for a freely circulating and for a bunched beam. The results obtained so far and the corresponding experimental conditions are given in Table 1.

The values of the cooling time τ and the strength of the longitudinal frictional force obtained in the experiment are better by almost two orders of magnitude than the values expected from the preliminary estimates[1]. It is now understood that cooling really depends on many different factors, the relative role of which is determined by the actual conditions in the storage ring with electron cooling.

Table 1 Typical experimental conditions and best results

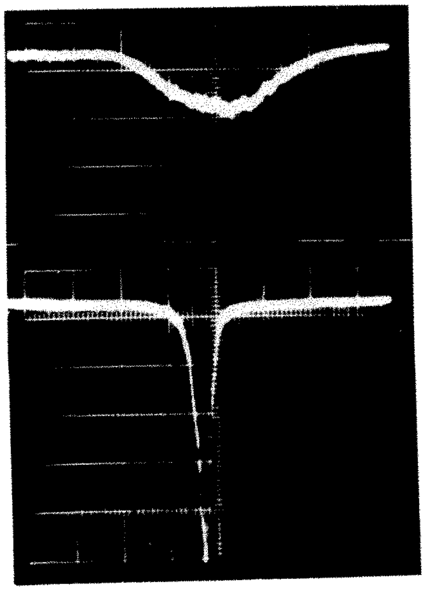
Proton momentum	0.35 GeV/*c*
Proton current	100 μA
Electron energy	35 keV
Electron current	0.5A
η	2×10^{-2}
Effective transverse electron temperature	0.2 eV
Effective longitudinal electron temperature	$<10^{-4}$ eV
Longitudinal magnetic field	1 kG
Cooling time	50 ms
Maximum longitudinal friction	1.5 MeV s^{-1}
Steady parameters of the cooled proton beam	
Diameter	0.5 mm
Angular spread	$\pm5\times10^{-5}$
Momentum spread	$<1\times10^{-5}$
Energy spread	<2 keV
Lifetime	10 h

Experimental possibilities

Electron cooling opens up possibilities in various areas of elementary particle and nuclear physics. Our survey[4] is devoted to their detailed discussion but here we shall confine ourselves to the most interesting examples which illustrate the promising nature of the electron cooling method.

Many experimental studies concern the storage of antiprotons, which is probably the most basic application of electron cooling. As an example, we shall give the parameters of the antiproton storage system proposed by the Nuclear Physics Institute for a planned accelerator storage ring complex at Serpukhov[4]. A simplified scheme for the complex is given in Fig. 4. Using the Serpukhov accelerator with the booster at present under construction (10^{13} protons per pulse, 2×10^{12} p s^{-1}), it is possible to accumulate 0.5×10^{6} $\bar{p}$ s^{-1} of 1.8 GeV/c momentum even without phase constriction of the proton beam in the accelerator. If we assume, optimistically, that it is possible to use the designed intensity of a proton beam of 10^{14} protons per pulse, then it is possible for a certain configuration of the system[4] to obtain 1×10^{9} $\bar{p}$ s^{-1}. But even an intensity of 0.5×10^{6} $\bar{p}$ s^{-1} would give a luminosity of up to 10^{31} cm^{-2} s^{-1} for $p\bar{p}$ intersecting beams of an energy of 2×10^{3} GeV. The first achievements in the storage of antiprotons have already allowed a wide range of new experiments to be carried out.

Fig. 3 Density distribution in proton beam before cooling (upper oscillogram) and after cooling (lower oscillogram). Horizontal scale: one large division corresponds to 1 mm.



In electron-cooled antiproton storage rings it is possible to perform a wide range of experiments with 'super-thin' internal gas and vapour targets. Here all the reaction products will be available for detection and analysis, including the slowly ionising fragments. In the superthin target case the antiproton energy losses and their fluctuation together with the multiple scattering of antiprotons on the target atoms are suppressed by the electron cooling, and the lift-time of the antiprotons is determined only by interactions with the target. For a good vacuum, the scattering on the residual gas is negligibly small. At high energies and for an accumulation rate of 10^{8} $\bar{p}$ s^{-1}, the luminosity may reach 10^{33} cm^{-2} s^{-1}, which is sufficient for a wide range of experiments.

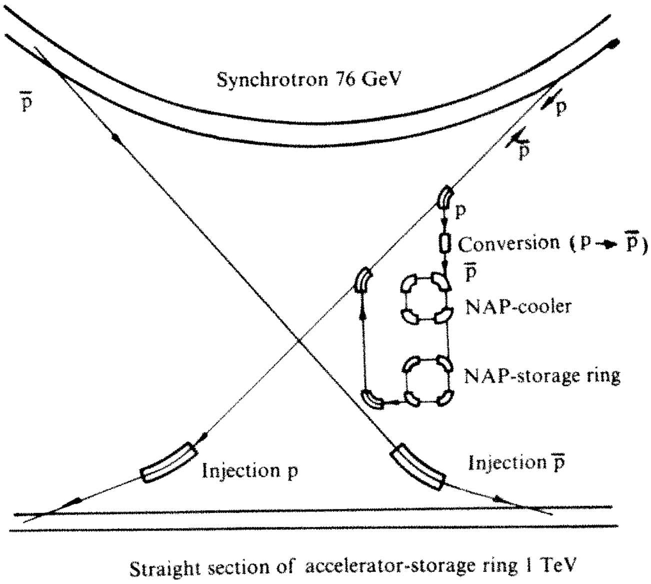


Fig. 4 Layout of proton–antiproton facility.

Superthin internal targets are particularly suitable for precision spectrometer experiments. Electron cooling in antiproton–proton and antiproton–nucleus experiments gives an energy resolution of the order of 10^{-4}–10^{-6} with satisfactory luminosity. Similar experiments with proton beams give the same high resolution, which is comparable with what can be attained in tandem accelerators and meson factories.

An important factor in spectrometer experiments is the possibility of very precise measurements of the absolute energy of particles of known mass in an accelerator by measuring the voltage accelerating the cooling electrons. Even today an accuracy of better than 10^{-5} may be attained.

Special possibilities are opening up in the study of $p\bar{p}$ interactions in experiments with continuously cooled beams in the energy range of 10 GeV per beam. Simultaneous cooling of the intersecting beams is possible even in a single ring (because the electrons, which cool protons, for example, will not perturb the antiproton beam, as its velocity has opposite direction). This set-up in comparison with the superthin target variant, may prove interesting if it is required to eliminate unwanted interactions with the target electrons and to reduce beam dispersion.

In particular, it is possible to investigate ψ-meson with a resolution much better than their intrinsic width, which is unattainable even in current experiments on e^-e^+ intersecting beams. Of course, only a very small proportion of all $p\bar{p}$ annihilation will take place via ψ-mesons even at resonance. Hence it is natural to look for the leptonic modes

$$p+\bar{p}\to\psi\to\begin{Bmatrix} e^{+}+e^{-} \\ \mu^{+}+\mu^{-} \end{Bmatrix}$$

The cross-sections of such processes at the resonance maximum is of the order of 100 nb. In a special storage ring with strong focusing at the intersection regions it is possible to obtain tens of thousands of such events per day.

We note that in $p\bar{p}$ collisions it is possible to obtain directly narrow states of the ψ-meson type with less strict constraints on quantum numbers than with e^-e^+ colliding beams, where the quantum numbers of such a state must be equal to those of the photon. It will be particularly easy to distinguish states with significant non-hadronic decay modes. An example of this type of meson is the $\chi(2750)$, decaying into two photons.

Using stored antiprotons, it is possible to obtain a beam of antihydrogen atoms. For this a parallel beam of cold positrons with the same mean velocity must be injected into one of the storage ring straight sections, through the electron-cooled antiproton beam. As a result of radiative recombination, the bulk of the antiprotons are converted into antihydrogen. Even on the NAP-M without special effort 10% of the protons are transformed into a beam of fast atoms.

Using this method it is possible to obtain beams of antiatoms of very low energy, which may permit neutral antihydrogen to be accumulated in a magnetic system which acts on antiatoms through the magnetic moment of the positron.

An important aspect of electron-cooled antiproton storage rings is the production of polarised beams of antiprotons. Today we consider the main variant to be the interaction of the stored antiproton beam with polarised superthin atomic hydrogen targets. According to existing data it is still difficult to choose optimal conditions combining a good degree of polarisation with minimal losses of antiptoton intensity.

One possible scheme is the interaction with longitudinally polarised protons in the storage ring section where the longitudinal polarisation of the antiprotons is stable. Here the difference in the total interaction cross-sections of antiprotons and protons of different relative helicities is used.

Polarisation experiments in storage rings seem feasible with antiproton beams. The method is adequate too for experiments with polarised protons and deuterons. Of course, polarised beams can only be obtained by directly storing polarised particles. The beams of accelerated polarised protons obtained so far and the existing polarised gas targets yield luminosities of not less than $10^{30}\,\mathrm{cm}^{-2}\,\mathrm{s}^{-1}$ under very clean conditions.

Electron cooling machines could already be proposed which may allow the intensity of the accelerated polarised proton beams to be increased to the level of existing proton beams of high-energy accelerators.

The use of electron cooling opens up the possibility of storing pure beams of antideuterons. The rate of accumulation of such beams is 10^{-4} of the rate of accumulation of antiprotons. In the superthin deuteron target case this would give luminosities of up to $10^{29}\,\mathrm{cm}^{-2}\,\mathrm{s}^{-1}$, which makes it possible to study in detail neutron–antineutron strong interactions, including annihilation processes. To distinguish these possibilities, it is necessary to register the antiprotons with small momentum loss and to select events with zero total charge of the remaining final particles, or to register the low-energy proton remaining after the decay of the neutron. The storage of antideuterons would be accompanied by the capture of mesons, antiprotons and antihyperons of momenta corresponding to the field and radius of the storage ring. It is not difficult to obtain a clean anti-deuteron beam: the mesons and antihyperons will decay rapidly, and the antiprotons may be removed by accelerating or retarding the antideuterons after storage with the aid of an electron beam, as described above.

There are also interesting prospects for experiments with stored ions, first in the superthin target regime using high monochromaticity of the cooled beams. Especially important is the use of electron cooling with ions which are difficult to obtain, principally heavy ions. However, working with these is complicated by radiative recombination with cooling electrons (the cooling is weakened in comparison with the radiative recombination proportionally to the mass of the ions). Hence it may be possible to cool these ions too, but it is impossible to keep them cooled for a long time. This problem may be solved by using proton cooling, for which the ion storage ring is supplemented by a proton storage ring, the straight section being common to both rings. The low temperature of the protons must be maintained by electron cooling.

Nevertheless, the most exciting of the immediate applications of electron cooling is still its use for experiments with intersecting $p\bar{p}$ beams at high energies.

By the time the first report on the principle of electron cooling appeared, a proposal for $p\bar{p}$ colliding beams (VAPP) had already been worked out in Novosibirsk. This proposal was published in 1971. It included a main storage ring with an energy of the colliding particles 2 × 23 GeV, the NAP antiproton storage ring of 1.1 GeV energy and an antiproton source. More recently a Fermilab project proposes to use the 500 GeV synchrotron as a $p\bar{p}$ colliding beam ring. Somewhat earlier the Nuclear Physics Institute had proposed the 2 × 2,000 GeV $p\bar{p}$ colliding beam project for UNK mentioned above. In this conservative approach a luminosity of $3\times10^{31}\,\mathrm{cm}^{-2}\,\mathrm{s}^{-1}$ may be attained, which is more than sufficient for carrying out first generation experiments.

The Fermilab project is in principle analogous to the VAPP/UNK project, except for one important point: the antiprotons 'generated' with an optimal energy of around 4 GeV after cooling are retarded to an energy close to 200 MeV which allows a certain gain in the storage rate. A synchrotron designed for periodic operation seems to allow intersecting beams of 2 × 300 GeV energy.

At CERN a project has been approved for a $p\bar{p}$ storage ring based on the 'stochastic cooling' method proposed in 1970 by Van der Meer.

Proton–antiproton ('quark–antiquark') intersecting beams permit the study of lepton pair creation processes.

$$p\bar{p} \rightarrow x \rightarrow \left\{ \begin{matrix} e^+ + e^- \\ \mu^+ + \mu^- \end{matrix} \right\}$$

in which both the electromagnetic and the weak interactions have a role. In particular, if the neutral intermediate boson Z^0 exists it may be found in these interactions if the total energy of the proton and antiproton exceeds the Z^0 rest mass by a factor of 3–6. Present estimates for its production require proton–antiproton beam energies in the region of 2 × (150–200) GeV. In this energy range, it would also be possible to observe the proposed charged vector basons $W^{\pm}$ of the weak interaction. It is also possible to search for heavy leptons in such experiments.

One can also study reactions in which a quark–antiquark pair is annihilated into a neutrino–antineutrino pair. Such a reaction is characterised by a visible energy reduced by a considerable fraction of the initial energy of the $p\bar{p}$ pair (of the order of 1/3); this loss will take place almost symmetrically with respect to the initial particles.

More detailed investigation will be possible with polarised $p\bar{p}$, and also pp and deuteron colliding beams. At the high energies considered, it is especially important to carry out experiments with longitudinally polarised particles at the intersection region. Electron cooling allows us to solve the problem of producing polarised proton and antiproton beams of the required intensity.

The quark approach to the interaction of protons and antiprotons emphasises the highly promising nature of experiments on colliding $p\bar{p}$ beams. But this does not exclude the possibility that the real physics of the interaction of matter and antimatter at super-high energies will prove to be still more interesting and entirely unexpected. In any case, there is no doubt that the first answer to these questions will be obtained in the next few years.

Bent beams and the overall size of extragalactic radio sources

A. C. S. Readhead, M. H. Cohen & T. J. Pearson
California Institute of Technology, Pasadena, California 91125

P. N. Wilkinson
Nuffield Radio Astronomy Laboratories, Jodrell Bank, Macclesfield, Cheshire, UK

In a small sample of extragalactic radio sources, curvature is found to be a common feature in bright radio components coincident with quasi-stellar objects. In 3C273 and 3C345 the curvature is smooth between the nuclear (<0.003″) and the outer (>1″) regions. This contrasts sharply with objects having comparatively faint central radio components, which are often well aligned with the extended features.

ONE of the most significant facts to emerge from VLBI studies of extragalactic radio sources is the high degree of alignment between the most compact and the most extended features. The objects in which good alignment has been seen are 3C111, 3C236, 3C390.3, 3C405 and NGC6251 (refs 1–5). These are all 'classical double' radio sources with steep spectra and large overall size (>100 kpc). In contrast to this, it has been found[6,7] that on different scales some objects exhibit a range of position angles. It has become increasingly clear that, in these objects, the occurrence of non-aligned structure is strongly correlated with other important properties. This effect has been noted independently by Davis *et al.*[8].

Here we describe new observations which show that in some objects the position angle changes systematically with distance from the nucleus, through an angle ≥20°, that is the objects are curved. The observations enable us to rule out several possible explanations of the differing position angles. We discuss two models which are consistent with all the observations and which account naturally for some of the properties of these objects. These two models have widely different implications for the physics of extragalactic radio sources.

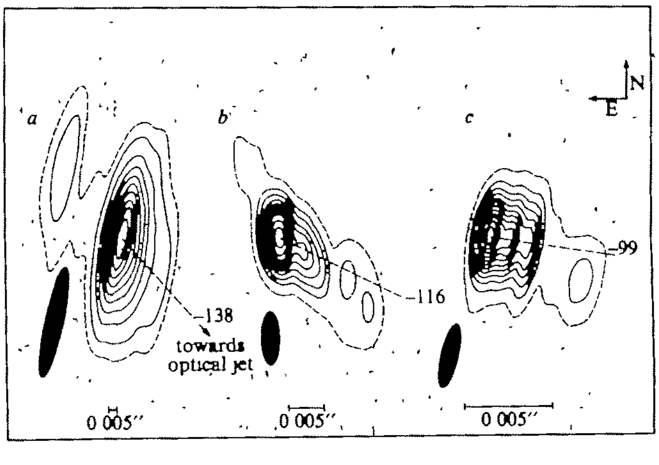
Straight and curved jets

Extragalactic radio sources can be divided into two major morphological groups: the first group consists of those objects in which the dominant radio emission comes from two components situated on opposite sides of the optical object and roughly equidistant from it. There may also be a radio component coincident with the optical object, but the total emission from it is small compared with that from the outer lobes. In general, these objects are large (≥100 kpc overall) and, at frequencies between ~200 MHz and ~5 GHz, they have steep spectra, $-1.0 \leq \alpha \leq -0.5$, where $S \propto \nu^{\alpha}$. We will refer to objects in this group as 'symmetric' or 'type S' objects, to emphasise that the dominant radio emission is roughly symmetrically placed on either side of the optical nucleus. The second group consists of objects in which there is a dominant compact (<1″) radio component coincident with the optical object, and if there are extended radio features these lie to one side of the optical object. These objects are generally small (≤100 kpc) and have flat spectra, $\alpha \gtrsim -0.5$, in the above frequency range. We will refer to objects in this group as 'core' or 'type C' objects, to emphasise that it is the coincidence of a dominant radio component with the optical nucleus which distinguishes them from type S objects.

Recent VLBI observations at 609, 1671, 5011 and 10,651 MHz not only confirm the different position angles seen on different scales in some objects, but also show that in at least two cases, 3C273 and 3C345, there is a smooth change in position angle between the compact and extended features. The details of the observations and analysis will be given elsewhere[9–11].

Figure 1 shows hybrid maps of 3C273 with three different resolutions made using the technique described by Readhead and Wilkinson[12]. The straight line through the brightest feature in each map, which we shall call the core, is drawn in the position angle of the feature closest to the core. Figure 1 shows that the

Fig. 1 Hybrid maps of 3C273 at three frequencies: *a*, 609; *b*, 5,011, *c* 10,651 MHz; showing the dominant structure on three different angular scales. The ellipses show the sizes (FWHM) of the restoring beams. The dashed line in each case is drawn through the radio core and the components closest to the core. The curvature of the source is clearly seen in both (*b*) and (*c*) maps. The systematic rotation of position angle from the smallest structure (*c*) to the largest structure (609 MHz map (*a*)) is also clear.



position angle of the radio structure in 3C273 rotates systematically with distance from the core. Figure 1*a* and *b* also shows features on the opposite side of the core, but further observations are needed to confirm these. The position angle of the larger-scale (~30 m arc s) structure agrees, to within the errors of observation, with that of the optical jet, which extends 20 arc s away from the nucleus. The total change in position angle, between the radio core and the optical jet, is 40°, over a distance of 70 kpc, assuming $H = 50\ \mathrm{km\ s^{-1}\ Mpc^{-1}}$ and $q_0 = 1/2$. Thus 3C273 is a type C object which shows pronounced curvature in the radio component coincident with the optical nucleus.

Four hybrid maps of 3C345 with different resolution are shown in Fig. 2. These again show a systematic change of position angle with changing resolution. In addition, Davis *et al.*[13] have discovered an elongated component in 3C345 which is 2 arc s away from the core in position angle (PA) −31°. This fits in well with the trend displayed by the source on smaller scales. Thus for 3C345 ΔPA = 45°.

In both 3C273 and 3C345 the curvature decreases as we move outwards from the core. Furthermore, the large-scale (>1 arc s) features in both cases are straight, that is they do not show curvature such as is seen near the core, and therefore, in both position and shape, these larger regions look like extensions of the compact inner regions shown in Figs 1 and 2.

These two sources provide the best evidence for a systematic rotation of position angle with distance from the radio core, but there are others which show the same tendency. For example, the 609-MHz hybrid map of 3C147 (ref. 6) shows a long narrow jet which is distinctly curved. This curvature is confirmed in a more recent map at 1,671 MHz (ref. 10). The large-scale (~0.7″) structure[14] also has a position angle different from that of the jet. The total change in position angle in 3C147 is 25°. Similarly, in 3C380 comparison of the 1,671 MHz hybrid map[10] with the Cambridge 5-km telescope map at 15 GHz (ref. 15) shows that ΔPA = 20°.

ΔPA, overall size, distance and morphology

Our observations of compact radio sources show that changes in position angle are common in type C sources, whereas as yet no example has been found of a non-aligned type S source. The data are given in Table 1 for nine sources, in order of increasing redshift. Figure 3 shows ΔPA plotted against the overall size, *D*, for each source. The sharp division in both ΔPA and *D* between core and symmetric objects is immediately obvious. These data show that the degree of alignment of the central radio objects is closely related to the overall size, the morphology and the distance class of extragalactic radio sources. The data shown in Table 1 should be viewed with some caution, however, as the sample of sources is not complete. But with the data presently available, the correlation between these four properties is very strong.

For this discussion we will assume that there is, in all cases, a unique source of high energy particles or radiation in the optical nucleus. We assume further that the energy is transferred to the outer components by a beam[16,17].

We have seen that type S objects tend to be large (>100 kpc) and to exhibit good alignment between compact and extended regions, while type C objects are curved and small (<100 kpc). The present observations are crucial, when seeking an explanation of these properties, because they enable us to eliminate some of the possible causes of non-alignment in type C objects. Rotation or precession of the energy source, or the possibility of two non-aligned beams, can be ruled out by the narrowness and alignment of the outer jets (3C273 and 3C345) or by the smooth curvature in 3C273 (Fig. 1). Similarly, curvature due to acceleration of the source by a nearby galaxy, as in 3C31 (ref. 18), would not explain why the curvature in 3C273 and 3C345 is greatest nearest the core. This would imply that the maximum acceleration, and hence the closest approach of the interacting galaxy, has occurred within the past few decades, which is very unlikely.

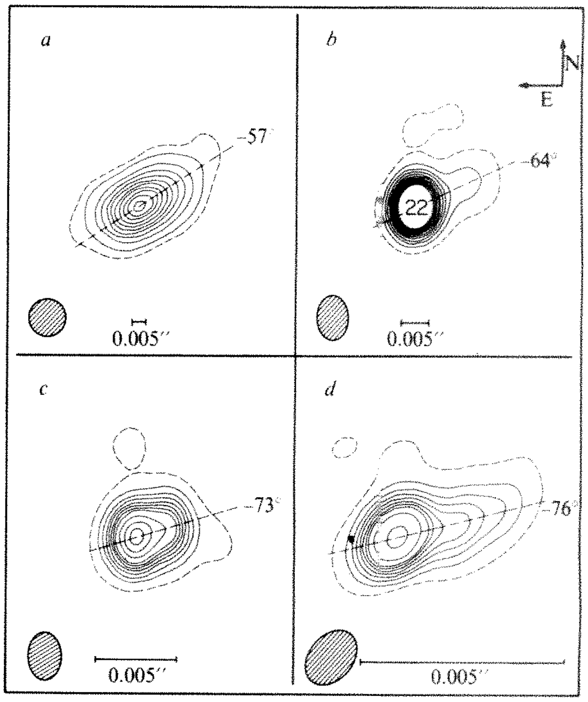


Fig. 2 Hybrid maps of 3C345 at four frequencies: *a*, 609; *b*, 1,667; *c*, 5,011; *d*, 10,651 MHz; showing the systematic rotation of position angle with structure on different scales.

Two possible explanations for the curvature are interesting because they can also explain the smaller overall sizes of type C objects.

(1) Beam bending by pressure: if the initial direction of the beam is not along the pressure gradient of the interstellar matter the beam could be bent by external pressure forces. The physical details of this mechanism have not been worked out, and the beam may be broken up by instabilities before bending through an appreciable angle. However, if it proves possible to bend the beam without destroying it, pressure bending becomes an attractive possibility because it could also explain many of the other observed features.

The bending of the beam by the external medium creates 'working surfaces' along curved portions of the beam. Thus we expect much greater interaction between the beam and the interstellar matter than in the case of a straight beam, which has only one working surface at the end. In sources bent by pressure we therefore expect to see 'hot spots' or knots along the beam, and we expect the brightest hot spots to coincide with the most strongly curved portions of the beam. This is entirely consistent

Table 1 Morphology, overall size, change in position angle and redshift of the objects in the sample*

Object	*Z*	*D* (kpc)	Type	ΔPA (deg)
NGC6251	0.023	2,900	S	≤4
3C111	0.0485	270	S	≤4
3C390.3	0.0561	320	S	≤5
3C405	0.0565	190	S	≤4
3C236	0.0989	5,700	S	≤3.5
3C273	0.158	70	C	40
3C147	0.545	5	C	25
3C345	0.594	25	C	45
3C380	0.691	40	C	20

Data either taken from text or from refs 1–5.

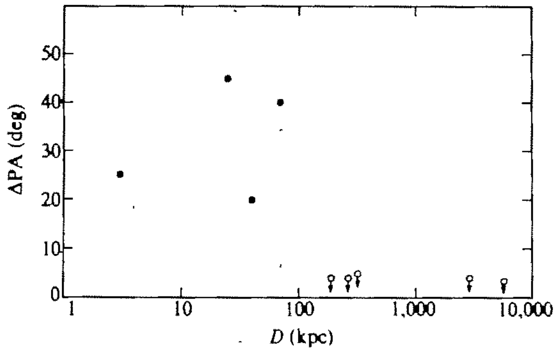

Fig. 3 The change in position angle (ΔPA) versus overall size (D) for the sources listed in Table 1: ○, type S sources, ●, type C sources.

with the observations of 3C273 and 3C345. Furthermore, much of the energy of a beam bent by external pressure forces would be dissipated inside the galaxy, and thus the beam would not travel as far. This could explain the smaller overall sizes of the curved sources and the bright synchrotron self-absorbed knots which we see in them[9]. In addition, on this model the curvature is greatest in the region of highest pressure gradient. We have seen, in 3C273 and 3C345, that the curvature is greatest at the core. This suggests the plausible explanation that the radio core is in the densest part of the galactic nucleus.

What causes the misalignment between the beam and the pressure gradient? This depends on the nature of the energy source. A strong possibility is a massive ($\gtrsim 10^8 M_\odot$) black hole[19–21], with the beam directed along the spin axis. As the black hole is formed from matter accreted from the galaxy, the angular momentum vector of the black hole, Ω_h, will be parallel to that of the nearby matter in the galaxy Ω_g. A strong gravitational interaction with another galaxy, which involves some transfer of matter, would change Ω_g to Ω'_g say, but leave Ω_h unaltered. Thus the angular momentum vector of the galaxy, and hence the pressure gradient, is no longer parallel to the beam. However, the black hole is accreting matter from the galaxy at a rate $\sim 1 M_\odot \text{yr}^{-1}$ (ref. 21), and after $\sim 10^7$ yr, by conservation of angular momentum, Ω_h will become aligned with Ω'_g. This scheme can also explain the good alignment observed in symmetric objects. We have seen that type S objects are larger, and therefore presumably older, than type C objects. Thus it may be that the good alignment in symmetric objects is related to their age. For example, Condon and Dressel[22] have shown that there is an increased probability of having a compact radio source in the nucleus of a galaxy if it is a member of a small group, or even a pair, of galaxies. Thus interaction with a nearby galaxy may trigger the production of a radio source as well as change Ω_g. This could explain why small (young) objects are curved whereas large (old, $>10^7$ yr) objects are well aligned.

(2) Projection effects: these must be present to some degree in every object and hence affect the values of ΔPA and D which we derive from the maps. They cause us to underestimate the total object size, and can lead to either an underestimation or an overestimation of ΔPA. They can give a natural explanation of both the curvature which we observe in type C objects and the alignment of type S objects, if we assume that all of these are formed by gently curving beams in which the total deviation from a straight line is very small ($\lesssim 5°$), and that in core objects the angle between the beam and the line of sight is small. A slightly curving beam appears strongly curved for most lines of sight almost parallel to the beam. If the radiating particles are moving at constant relativistic speeds along a narrow beam, the projection effects can also explain why the curvature is greatest nearest the core: the radiation is strongly beamed in the forward direction and the positions of maximum brightness and maximum curvature coincide as these both occur at the point where the beam is most nearly parallel to the line of sight. Therefore the majority of nuclear jets detected in a flux-limited sample will be directed towards the observer, and any intrinsic curvature will be strongly amplified by the projection effect. The one-sided structure in 3C273 and 3C345 shows that the radio core coincides with the origin of the beam. If this were not the case the maximum curvature and brightness would occur at an intermediate position along the visible portion of the beam.

The visible features in the maps all have roughly comparable flux densities, and, because the enhancement of apparent brightness by relativistic beaming is a very strong effect, this implies that all features in the maps must be moving at relativistic speeds towards the observer. If this were not the case, the intrinsic luminosities, over 4π sr, of the stationary and moving features would have to differ by large factors which fortuitously cancel the effect of relativistic beaming. Thus the intrinsic luminosity of the central radio sources in core objects is low, and they are not as different from the central sources in symmetric objects as they appear. In symmetric objects the beam is significantly offset from the line of sight which helps to explain why the type S objects in our sample are generally nearby whereas the type C objects are more distant, because we have to observe a large volume of space to find a significant number of objects with beams pointing towards us. Furthermore, the superluminal velocities[23], like those observed in 3C273 and 3C345, are expected on this model in sources in which the angle between the line of sight and the beam is small. This is true even if all the features are moving towards the observer at relativistic speeds. The relative motion which is observed could be due to the bending of the beam, as the apparent velocity depends on the angle between the line of sight and the beam, or it could be explained if the various features have differing velocities.

Projection effects alone cannot account for all of the observed differences between core and symmetric objects. This point is considered by Scheuer and Readhead[24], who show that some of the remaining differences can be removed by a simple extension of the model. The details of this model and the further implications for superluminal sources and for extragalactic objects in general are discussed elsewhere[24,25].

We suggest that one of the above possibilities, either projection of beam bending by the external medium, is the dominant effect responsible for the curvature in most type C objects. However, it is not possible to discriminate between these alternatives with the present observations. This may become possible in the future if we can follow the progress of individual radio knots along the beam. For example, if projection effects dominate, and if the radiating particles are moving with relativistic bulk velocity, v, along the beam, the apparent transverse velocity of a knot is a maximum at an angle θ to the beam, where $\cos\theta = v/c$. Thus, in a slightly curved beam the apparent transverse velocity passes through a maximum at the point where the angle between the line of sight and the beam is closest to θ. One might therefore see the knots speeding up as they approach this point and slowing down as they move away from it. Observations of such behaviour would be strong evidence in favour of the projection argument, although it might be possible to arrange conditions in the external medium to mimic the effect in a beam bent by pressure forces. Conversely, if the velocity of the knots is found to be constant over a substantially bent portion of the beam this would be strong evidence against the projection argument.

Conclusion

We have shown that the occurrence of non-aligned radio structure in the nuclei of extragalactic radio sources is strongly correlated with three other important properties—morphology, overall size and redshift. Our observations have enabled us to rule out several possible explanations for the misalignment of type C objects. Two plausible explanations consistent with the observations are external pressure bending and projection. These are totally different in many important physical aspects. If the curvature is due to external pressure forces then the bulk velocity of the radiating particles along the jet could be nonrelativistic, and the jet one-sided, that is we see all of the object.

If we are observing a projection effect in a jet with relativistic bulk motion, the jet could actually be two-sided, that is we may only see half of the object. The projection effect can only amplify a pre-existing curvature, however, and pressure may be responsible for this curvature.

Both models can explain the coincidence of maximum curvature with maximum brightness, but the projection argument is more attractive because it also accounts automatically for the superluminal velocities observed in some type C objects and the correlation of curvature with distance.

Olivine fractionation equations for basaltic and ultrabasic liquids

T. H. Pearce
Queen's University, Kingston, Ontario, Canada, K71 3N6

Exact equations are derived for fractionation curves of basaltic and ultrabasic liquids. The ideal fractionation equation has the form $y = ax^K$ *while equilibrium crystallisation has the form* $(1/y) = Km_1(1/x) + b_1 \cdot (1-K)$, *and batch fractionation,* $y = Km_2 + b_2 \cdot (1-K)$. *A ratio transformation as in Pearce diagrams allows natural data to be analysed to determine if a constant distribution coefficient fits the data: K may also be determined directly. Published data for a series of liquids fractionated from a lunar picrite parent have been analysed using the equilibrium equation. The average K value is* $K = 0.323$ *with a linear correlation coefficient,* $R = 0.996$. *The reported olivine analyses yield a* $K = 0.321$ *for the same set of experiments. Using the ideal fractionation equation, the liquid line of descent can be calculated and constraints placed on the primitive liquids which produced a given mafic rock by olivine fractionation.*

GIVEN the chemical composition of a series of rocks allegedly representing liquids which have fractionated olivine from a single parent, we should be able to use fractionation curves of the type introduced by Bowen[1], and Osborne and Schairer[2] to test this hypothesis. However, until the present work, the equations of exact fractionation curves requiring only chemical data had not been developed. This problem may be treated by rather complicated equations involving the fraction of material transferred from liquid to solid (see ref. 3). Of course, in dealing with natural data, the fraction of liquid converted to solid is not generally known and must be estimated. These equations, although complex, may be used to generate models on a trial and error basis. Alternatively, a step-wise computer program such as developed by Roeder[4] can approximate the fractionation curve (however, the increments must be small because the error is cumulative).

Unless the equations are known explicitly, it is difficult to judge how well the natural data fit various fractionation models, and extremely difficult, if not impossible, to derive a model directly from the data.

Ideally one would like to express the fractionation, either ideal (Rayleigh-type) or equilibrium, in such a simple form that it can be rearranged in a linear form with predictable slope and intercept. The direct analysis of observed distribution coefficients would then be possible and trial and error methods would be unnecessary.

Here, I will develop such equations in absolute units and show how they may be used to analyse natural data to determine not only if the distribution coefficient is constant, but also to evaluate it directly from the natural data. To use the equations, the data must be transformed using a simple transformation[5,6] which eliminates the closed array property of data expressed as a per cent (or fraction of the whole). Many petrologists may not be familiar with the properties of such a transformation, and I will briefly explain the technique below.

Some theoretical considerations

In 1968, I proposed that certain types of ratio diagrams in which the denominator is a constant (Pearce diagrams) be used to analyse data in which a system may be considered to have progressively changed composition. The actual chemical rate of change of constituents in such a case is modelled exactly by considering absolute amounts of the constituents (grams, tons, mols and so on). In so doing, we are treating chemical variables exactly like the extensive (thermodynamic) properties of thermodynamics.

Erroneous results may be obtained by considering variations in weight per cent. Harker diagrams, for example, are particularly misleading as they plot SiO wt % on the abscissa as though it were an independent variable. SiO_2 wt % is not a single variable representing the silica content of a rock, it is rather a complex variable composed of at least 11 other variables (the other components of the rock). The closed array or, constant sum property, of weight per cent data also causes difficulties for statistical manipulations[7].

There is another problem with per cent data (and all natural chemical data). That is, the variables cannot be separated to give the absolute units which exactly describe the system. It is extremely difficult to apply the usual mathematical techniques to a complex variable (such as wt % SiO_2), itself composed of 12 simple variables. A ratio transformation of the data produces a mathematically simpler form (we only have two variables). The simplest possible result occurs when the denominator is a constant as in Pearce diagrams. It is a characteristic of this transformation that it allows us to obtain the same results as though the variables were separated.

This method of treating data is explained as follows, if we have a relationship between y and x, say

$$y = f(x) \tag{1}$$

then

$$\left(\frac{y}{z}\right) = g\left(\frac{x}{z}\right) \tag{2}$$

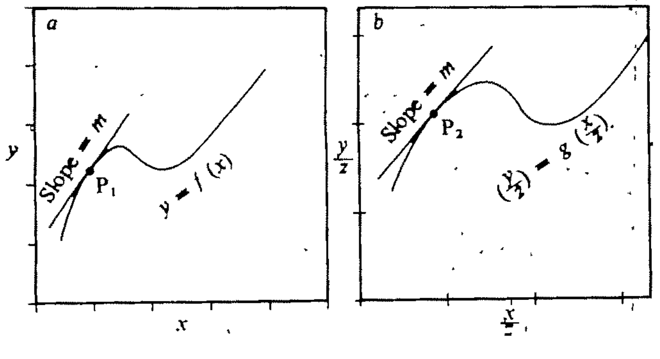
Equation (1) has the same form as (y/z) versus (x/z), from equation (2), only if z is a constant in the mathematical sense. As $y/z = y\%/z\%$, these ratios are easily evaluated. In effect we are magnifying the curve $y = f(x)$ without changing its shape. Examining the problem graphically, we wish to obtain the relationship in Fig. 1*a*. We cannot do this because we cannot obtain the absolute values of y and x from closed array data (percentage values). We can, however, obtain the graph in Fig. 1*b* from which we have the same important information as from Fig. 1*a*, namely the rate of change of y with respect to x.

Every point on $y = f(x)$ has a corresponding point on $(y/z) = g(x/z)$ which bears the same relationship to y and x (that is, the slopes are the same). Thus, we can determine the true relationship between y and x by plotting $y\%/z\%$ against $x\%/z\%$ remembering that z must be a constant. This is the point of the transformation of data in a Pearce diagram and has practical applicability far beyond its mathematical simplicity. I shall use it here to calculate the distribution coefficient between olivine and liquid using only the composition of a series of liquids from which olivine has been fractionated.

Ideal fractionation equations

During ideal fractional crystallisation it is assumed that the crystals are effectively removed from the liquid as they are formed so that there is no reaction between crystals and liquid. In this case, we know, therefore, that the chemical rate of change of the liquid composition is the same as the composition of the olivine being precipitated. If we assume the distribution coefficient is constant, we can now derive the equation for ideal fractionation of olivine from the liquid as follows.

Fig. 1 *a*, An hypothetical graph of two related variables y and x in absolute values (grams, tons, mols) In general this type of graph cannot be determined from natural chemical data; *b*, as for *a* but with the data transformed by dividing by z, a constant. Point P_2 corresponds to point P_1 and has the same slope. In fact, as corresponding points yield the same slopes, the curve has the same shape as in (*a*).



Let y = amount of FeO in absolute units (such as, grams, tons, mols); x = amount of MgO in the same units as y; K = distribution coefficient as defined by Roeder and Emslie[8].

$$\left(\frac{\mathrm{FeO}}{\mathrm{MgO}}\right)_s = K\left(\frac{\mathrm{FeO}}{\mathrm{MgO}}\right)_L \tag{3}$$

where subscripts S, refers to solid or crystals; L, refers to liquid; i, refers to the 'i' differentiate formed; p refers to the parent. x_0 = the original amount of MgO in the system (parental MgO); y_0 = the original amount of FeO in the system (parental FeO); c_1 and so on = a constant.

Now

$$\left(\frac{y}{x}\right)_s = K\left(\frac{y}{x}\right)_L \tag{4}$$

As the crystals are physically removed from the liquid the instant they form, it follows that

$$\left(\frac{dy}{dx}\right)_L = \left(\frac{y}{x}\right)_s \tag{5}$$

considering the liquid path

$$\left(\frac{dy}{dx}\right)_L = K\left(\frac{y}{x}\right)_L \tag{6}$$

or

$$\frac{dy}{y} = K \cdot \frac{dx}{x} \tag{7}$$

integrating equation (4)

$$\int \frac{dy}{y} = K \int \frac{dx}{x} + C_1 \tag{8}$$

$$\log y = K \log x + C_1 \tag{9}$$

evaluating the integration constant C_1

$$\log y = K \log x + \log (y_0/x_0^K) \tag{10}$$

or

$$y = \left(\frac{y_0}{x_0^K}\right) \cdot x^K \tag{11}$$

These simple equations describe the exact shape of the ideal fractionation curve in absolute amounts and may be used to model olivine fractionation. They cannot be used to analyse natural data because natural chemical data cannot be separated into discrete, simple, variables. However, by using the transformation of a Pearce diagram, we can achieve the same result. Therefore, using theorem 1 of Pearce[5]: y/z versus x/z will give us the same relationship as y versus x, and therefore

$$\log\left(\frac{y}{z}\right) = K \log\left(\frac{x}{z}\right) + \log\left(\frac{y_0}{x_0} \cdot z^{K-1}\right) \tag{12}$$

and

$$\left(\frac{y}{z}\right) = \left(\frac{y_0}{x_0}\right) \cdot \left(\frac{z_0}{x_0}\right)^{K-1} \cdot \left(\frac{x}{z}\right)^K \tag{13}$$

Both equations (12) and (13) may be used to analyse natural data but equation (12) is more useful as it gives a straight line with slope K on a $\log(y/z)$ versus $\log(x/z)$ diagram. Thus the presence of a constant distribution coefficient as well as its value may be determined from natural liquid compositions. Rewriting equation (12) in terms of oxide constituents

$$\log\left(\frac{\mathrm{FeO}}{\mathrm{Al_2O_3}}\right) = K \log\left(\frac{\mathrm{MgO}}{\mathrm{Al_2O_3}}\right) + \log\left(\frac{\mathrm{FeO}}{\mathrm{MgO}}\right)_p \cdot \left(\frac{\mathrm{Al_2O_3}}{\mathrm{MgO}}\right)_p^{K-1} \tag{14}$$

Note that in equations (12) and (13) the exact size of the system need not be specified as the equation does not change with the size of the system.

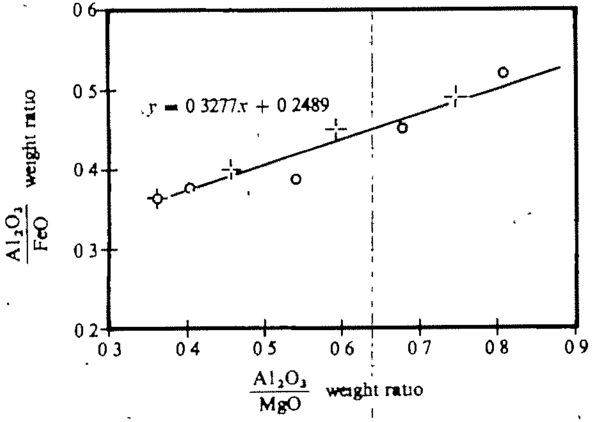


Fig. 2 Weight ratio data for fractionated liquids from a lunar picrite. The points are both actual experimental data (O) and smoothed data (+). The linear regressive line has a linear correlation coefficient of $R = 0.996$. The average K determined from both slope and intercept is 0.323. Walker *et al.* report data giving an average K of 0.321 Note that this type of 'inverted data' graph should only be used to analyse the K values for liquids which have formed by equilibrium crystallisation.

Equilibrium crystallisation equations

During equilibrium crystallisation there is continuous, complete reaction between the crystals and coexisting liquid. At any instant there is only one solid composition which represents the total amount of crystals which have formed, and the system consists of only two phases, crystals and liquid. Unlike ideal (non-reactive) fractionation, we do not know, at first sight, the chemical rate of change of the liquid (dy/dx), however, we do know that, because of the constant composition constraint, (in absolute amounts):

$$y_0 = y_s + y_L \tag{15}$$

and

$$x_0 = x_s + x_L \tag{16}$$

also

$$\left(\frac{y}{x}\right)_s = K\left(\frac{y}{x}\right)_L \tag{4}$$

therefore, combining equations (15), (16) and (4), in terms of the liquid curve

$$\left(\frac{y}{x}\right)_L = \frac{1}{K}\left(\frac{y_0 - y_L}{x_0 - x_L}\right) \tag{17}$$

As we are concerned only with the liquid, we can drop the subscripts and rearrange equation (17) by cross multiplication to give the simple form

$$\left(\frac{1}{y}\right) = K\left(\frac{x_0}{y_0}\right)\left(\frac{1}{x}\right) + \frac{(1-K)}{y_0} \tag{18}$$

This is the equation of a straight line with slope $K(x_0/y_0)$ and y-intercept $(1-K)/y_0$ if $(1/y)$ is plotted against $(1/x)$. This equation may be used for modelling but it cannot be used directly to analyse natural data because it is written in absolute amounts. Using the transformation advocated here, substituting y/z and x/z for y and x

$$\left(\frac{z}{y}\right) = K\left(\frac{x_0}{y_0}\right)\left(\frac{z}{x}\right) + \left(\frac{z_0}{y_0}\right) \cdot (1-K) \tag{19}$$

Rewriting in terms of oxide constituents

$$\left(\frac{Al_2O_3}{FeO}\right)_l = K\left(\frac{MgO}{FeO}\right)_p \cdot \left(\frac{Al_2O_3}{MgO}\right)_l + \left(\frac{Al_2O_3}{FeO}\right)_p \cdot (1-K) \tag{20}$$

These ratios, which are readily determined from chemical analyses, may be in any units and K calculated from the slope will be the same. Of course, any element, oxide or extensive variable of the system could be used as the denominator of the ratios as long as it is constant. However, it is convenient to use Al_2O_3 or $(Al_2O_3 + CaO)$, although TiO_2 is also useful (especially if one attempts to model plagioclase fractionation in addition to olivine).

Batch fractionation equations

In batch fractionation, which is essentially a disequilibrium non-reaction process, we assume a constant composition of olivine determined by the original liquid composition and distribution coefficient. The equation for such a process is

$$y = K\left(\frac{y_0}{x_0}\right)x + y_0 \cdot (1-K) \tag{21}$$

or applying the transformation as in Pearce[5]

$$\left(\frac{y}{z}\right) = K\left(\frac{y_0}{x_0}\right)\left(\frac{x}{z}\right) + \left(\frac{y_0}{z_0}\right) \cdot (1-K) \tag{22}$$

Rewriting in oxide form using Al_2O_3 as a divisor we have

$$\left(\frac{FeO}{Al_2O_3}\right)_l = K\left(\frac{FeO}{MgO}\right)_P \cdot \left(\frac{MgO}{Al_2O_3}\right)_l + \left(\frac{FeO}{Al_2O_3}\right)_P \cdot (1-K) \tag{23}$$

Analysis of liquid composition

If we have the compositions of a series of liquids produced by ideal fractionation of olivine, then from equation (14) it is clear that a plot of (FeO/Al_2O_3) versus (MgO/Al_2O_3) will be linear with a slope of $m = K$ and a y-intercept of

$$b = \log\left(\frac{FeO}{MgO}\right)_P \cdot \left(\frac{Al_2O_3}{MgO}\right)_P^{K-1} \tag{24}$$

Thus we have two ways of evaluating K from a single graph.

Unfortunately I do not have access to natural data to demonstrate the effectiveness of this technique. However, data are available for equilibrium crystallisation and that will be analysed below.

Table 1 Lunar picrite observed and calculated liquid compositions

	1	2	3	4
	180	184		1250
FLIQ	1.00	0.83	0.83	0.84
Olivine mol %	77.3	69.4	68.7	72.1
Olivine observed	—	69.7	—	—
SiO_2	43.8	44.0	45.3	44.3
TiO_2	2.80	3.33	3.4	3.3
Al_2O_3	7.95	9.63	9.68	9.5
FeO	22.0	21.3	21.7	21.1
MnO	0.29	—	0.35	—
MgO	13.5	8.69	8.55	9.8
CaO	8.18	9.95	9.96	9.5
Na_2O	0.22	—	0.27	0.30
K_2O	—	—	0	0.07
Cr_2O_3	0.65	—	0.79	1.0
	99.39	96.90	100.00	98.87

Analyses 1, 2 and 4 from Walker *et al.*[9]. FLIQ is the fraction of liquid remaining after fractionation. Olivine mol % is the equilibrium olivine calculated from equation (3) assuming a K of 0.32. Olivine observed is the actual olivine analysed by Walker *et al.*[9]. 1. Starting composition, lunar picrite 12002. 2. Liquid fractionated from 12002 by olivine fractionation. 83% of the liquid remains. Compare this composition with nos 3 and 4. 3. Fractionated liquid calculated using equation (18) and summing the absolute amounts to 100%. Note the close agreement with the experimental run no. 2. 4. Walker *et al.*[9] reported this fractionated composition for 1,250 °C and 84% liquid remaining. Compare with nos 2 and 3 Note that the MgO content is slightly high resulting in a calculated olivine slightly enriched in forsterite.

In the case of equilibrium crystallisation it is clear from equations (19) and (20) that a plot of (Al_2O_3/FeO) against $(Al_2O_3)/MgO) \cdot (MgO/FeO)_p$ will be linear with a slope of $m = K$, and a y-intercept of

$$b = \left(\frac{Al_2O_3}{FeO}\right)_p \cdot (1-K) \qquad (25)$$

Thus, in this case also, we have two different ways of evaluating K from the same graph.

Walker *et al.*[9] have reported experimental data for equilibrium crystallisation of olivine from a lunar picrite. These data are plotted in Fig. 3 and may be used to evaluate the nature and value of the distribution coefficient. Note that in this case the x-values are multiplied by $(MgO/FeO)_p$ to yield a slope of K. Using Walker's fractionated liquid values the observed K calculated from the liquids is 0.328 (from the slope) and 0.319 (from the intercept) giving an average value of 0.323. This compares favourably with the average K of 0.321 calculated from the reported liquid and olivine compositions. Table 1, shows compositions calculated using equation (18) and summing the absolute amounts to 100%: the excellent agreement requires no further comment (see Fig. 3).

Table 2 Calculated parental liquids for an abyssal tholeiite

	1	2	3	4	5	6

1, Abyssal tholeiite studied by Fujii and Kushiro[10] The composition was adjusted to give $Fe_2O_3 = 0\ 40$ and summed to 100% 2–6, Possible parental liquids for no. 1 calculated using equation (11) and summing the absolute amounts to 100%. The assumptions are: $K = 0.30$ and ideal fractionation of olivine Composition no. 4 has 52 1% olivine added and is in equilibrium with olivine of $Fo_{92.4}$. Composition nos 1–6 define the olivine-controlled liquid line of descent which leads to the abyssal tholeiite no 1

Calculation of primitive liquids

There is another way in which the explicit equations developed here may be used in petrogenetic theory. The family of curves described by equation (11) are, in effect, olivine-controlled liquid lines of descent. Considering the form of the equations, it is clear that a single point on the curve defines the equation. Therefore, only one ideal fractionation curve passes through any given composition. The consequence of this is important. If a single differentiate is known, then all possible parental liquids may be calculated exactly. As ideal fractionation is a limiting case, limits may be placed on the compositions of peridotitic liquids which may be parental to a given basic or ultrabasic liquid; always assuming, of course, that K is constant, and known. Table 2 shows a set of primitive liquids calculated for a recently studied abyssal tholeiite[10].

Unlike ideal fractionation, the equation for the family of equilibrium curves contains two parameters (in addition to K). Thus two points on any curve are necessary to define that curve. As a consequence of this, a given mafic liquid never lies on a single equilibrium crystallisation line of descent. An infinite number of equilibrium curves pass through any given composition. Thus the constraints on possible parental compositions are more complicated than in the case of ideal fractionation. A discussion of the details of determining the parent line of composition is beyond the scope of this work, and will be reported later.

Discussion

While developing these equations, some problems of applicability to natural data became apparent. First, most petrologists are still publishing whole rock analyses of porphyritic rocks. Bowen[11] has pointed out that whole rock compositions do not necessarily represent liquids, hence whole rock compositions have limited value in petrogenetic studies. The modern approach would seem to be to analyse the matrix separately. Such data would give the liquid line of descent directly and be more useful in theoretical studies. Attempts to correct whole rock analyses to a phenocryst-free composition by using modal analyses are unsatisfactory. The errors introduced by the modal analyses are such as to render the resulting data virtually worthless. Second, the value of K determined from the above equations is extremely susceptible to errors in analyses. Therefore, it is suggested that in some studies replication of analyses may be useful. Alternately, smoothing the data to a curve, as in ref. 9, seems to work well, especially if there are only a few points on the line.

Although calculation of liquid composition is the main concern of the present work, calculation of the total solid composition is readily accomplished by subtracting the liquid composition at any point from the starting composition.

In spite of the different form of the equations for ideal and equilibrium fractionation, the results for differentiation of basalt are rather similar. In fact, for small degrees of fractionation they may be difficult to distinguish. However, the two equations are fundamentally different. If, for example, at any point during equilibrium crystallisation the liquid is isolated from the solid, then the system initiates a new curve from that point. For ideal fractionation, on the other hand, only a single curve exists.

It may be worth noting that the fractionation curves are independent of temperature as long as K is independent of temperature. The equations reported here, although developed for olivine fractionation, are completely general, and were developed in terms of y and x to emphasise this generality. The equations, therefore, apply not just to olivine, but to any mineral for which K is constant and which has a solid solution between two end-members. The equations apply directly to orthopyroxene and clinopyroxene (if conditions are such that K is constant). Plagioclase is a more difficult case, but similar equations are being developed for plagioclase fractionation and these will be published later.

I thank P. L. Roeder and T. N. Irvine whose work motivated me to tackle this problem, and P. L. Roeder for the results of his olivine fractionation program which greatly helped in the development of the equations. The mathematical derivations were reviewed by H. Kummer but any errors are mine. L. Dykes did the drafting and key-punching for the computer runs. This work was supported by NRC of Canada operating grant A-8709.

Degenerate perturbations of protein structure as the mechanism of anaesthetic action

The interaction of the n*-alkanols with lipid bilayers and excitable membranes shows that there is no simple correlation between conduction block and any of the perturbations of bilayer structure currently proposed as unitary mechanisms of local anaesthetic action. We propose instead that the* n*-alkanols act by direct interaction with target proteins to cause perturbations which depend directly on the precise structure of the alcohol.*

A CLASSICAL EXAMPLE of nonspecific drug action lies in the effects of local anaesthetics on isolated nerve preparations. The extraordinary range of chemically diverse structures which will cause reversible conduction block suggests that there can be no specific chemical interaction between a unique receptor site on the proteins responsible for nerve conduction and all the molecules which have local anaesthetic activity. Nevertheless, it has been widely assumed as a working hypothesis that there may be a common structural perturbation in the excitable membrane which is caused by all anaesthetics irrespective of their structure and which is sensed by the target proteins[1]. The underlying rationale for such unitary hypotheses derives from the experimental evidence that anaesthetic potency correlates approximately with the oil–water partition coefficient of the anaesthetics[2], implying that anaesthetic action occurs when about the same number of molecules interact with the excitable membrane. The assumption is that, as the bound anaesthetics at the same membrane concentration all perturb function to about the same extent, they may all do so by the same molecular mechanism[3].

However, there has been no direct experimental evidence for any unitary mechanism because it has not yet been possible to analyse directly the interaction of anaesthetics with the target protein structures in the excitable membrane. For this reason many other membranes[4,5] have been used as models to analyse the perturbation of membrane structure and function by anaesthetic molecules. Unfortunately, as a direct consequence of the nonspecific nature of the interactions, virtually every physical and biochemical parameter which can be measured may be affected, many at, or just above, the concentrations required for local anaesthetic action[6]. Despite the problem of identifying the relative importance of these many perturbations, studies have focused attention on two contrasting classes of structural perturbation as candidates for a unitary mechanism of anaesthetic action. These are perturbations of the structure of the lipid bilayer leading indirectly to perturbations of the target protein structures, or alternatively, perturbations of the target protein structures through their direct interaction with the anaesthetics.

Here we compare the effects of n-alkanols on various properties of the lipid bilayer with their ability to block nerve conduction, which provides a critical test to distinguish between these two main hypotheses.

Perturbations of fluidity and phase transitions by *n*-alkanols

The effects of the n-alkanols on the fluidity of a range of defined lipid bilayers was estimated using the spin label technique. The ratio of the low-field to mid-field peak heights (h^{-1}/h^{0}) was used as an arbitrary measure of bilayer fluidity to demonstrate the effects of fluidity on the short- and long-chain n-alkanols. As an example, Fig. 1 (see legend for details) shows the effects of butanol and dodecanol, separately and in combination, on dioleoyl phosphatidylcholine (DOPC) and oleoyl palmitoyl phosphatidylcholine (OPPC) with and without cholesterol, for spin-labelled phospholipids carrying the nitroxide group at C-16. These lipid mixtures were selected to span the range of bilayer fluidity likely to be found in excitable membranes. Similar results were obtained when the spin label was in the C-7 or C-10 position (not shown).

In general, a similar pattern of opposing perturbations and antagonistic effects of the two n-alkanols in combination is obtained irrespective of the composition of the lipid bilayer or the spin label used. In detail, the magnitude of the effects varies, in that the decrease in fluidity caused by dodecanol is small in bilayers containing high proportions of cholesterol, which is itself a potent rigidifying agent, and the spectral changes observed with the nitroxide at the C-7 position are marginal with either alkanol. Similar results are obtained with other pairs of short- and long-chain n-alkanols; n-alkanols with a chain length of <10 carbon atoms increase membrane fluidity whereas those with a chain length >10 carbon atoms decrease it (not shown). The general conclusion, that the short- and long-chain n-alkanols cause opposing changes in bilayer fluidity holds not only for the defined lipid mixtures, but also for bilayers of lipids extracted from erythrocytes (not shown).

We assume that the same conclusion will probably apply to the effects of the alcohols on the fluidity of the lipid bilayer in excitable membranes, particularly as the lipid composition of the axonal membranes closely resembles that of the erythrocyte membrane[7,8]. A similar pattern of responses emerges from the effects of the n-alkanols on the transition temperature ($T_t = 23.5$ °C) of dimyristoyl phosphatidylcholine (DMPC) (Fig. 2*a*); the short-chain alkanols depress T_t, whereas the long-chain alkanols increase T_t, as reported previously[9,10]. The effect of butanol on DMPC–dodecanol mixtures (2 : 1 and 1 : 1) shows the consistent antagonistic action of the combined alkanols on T_t (Fig. 2*b*). Similar results were obtained with dipalmitoyl phosphatidylcholine, and the increase in T_t with the long-chain alkanols does not therefore depend on any precise relationship between the chain length of the alkanol and that of the lipid.

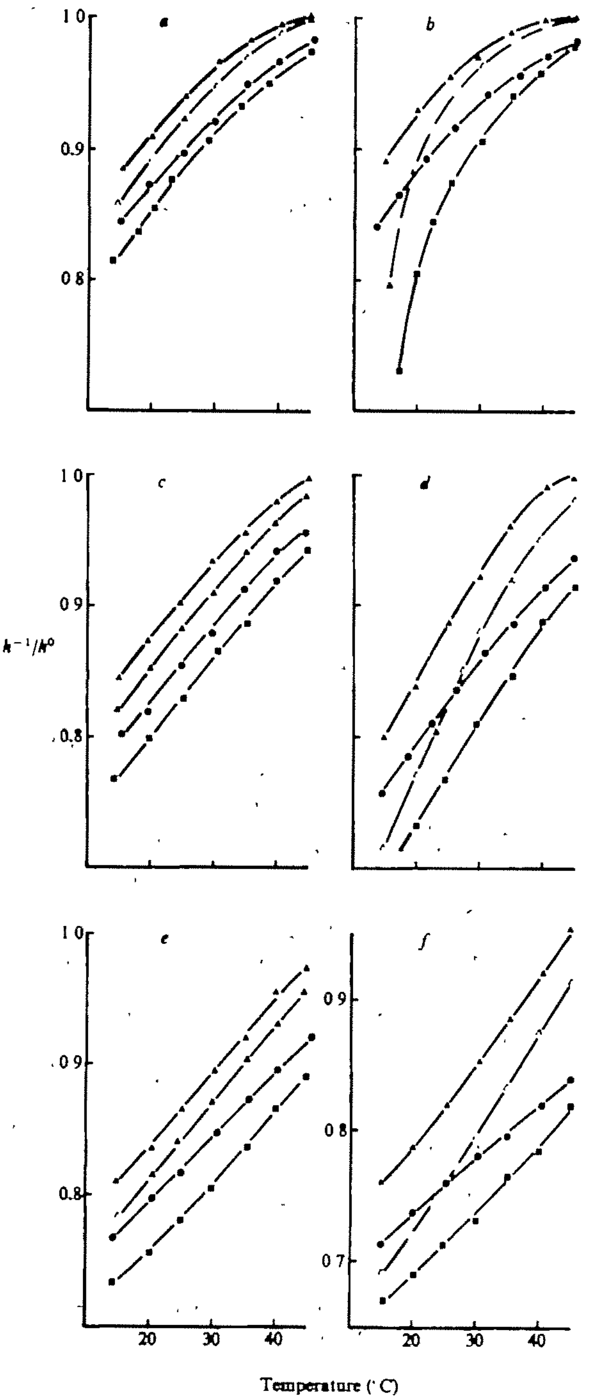

Fig. 1 The effects of butanol (C_4) and dodecanol (C_{12}) on the fluidity of dioleoyl phosphatidylcholine (DOPC) and palmitoyl phosphatidylcholine (OPPC) bilayers, and mixtures of these lipids with cholesterol (Ch). The phospholipids, synthesised by the method of Robles and van den Berg[36], were dissolved in $CHCl_3$ with spin label (1 mol%), with or without added cholesterol and C_{12}. The samples were dried under N_2 and resuspended in 100 mM potassium phosphate buffer, pH 7.2, to give a final concentration of 75 mg ml^{-1} phospholipid. For experiments in 150 mM C_4, the alkanol was added to the buffer before resuspension of the dried lipid samples. The spin labels used were the N-oxyl-4',4'-dimethyloxazolidine derivatives of 1-palmitoyl-2(n-ketostearoyl) phosphatidylcholine ($n = 7$, 10 or 16) (results for $n = 7$, 10 not shown). Spectra were recorded on a Varian E3 EPR spectrometer with a variable temperature controller. The fluidity was estimated arbitrarily from the ratio of the low-field to mid-field peak amplitudes (h^{-1}/h^0) (ref. 37), where an increase in this ratio indicates an increase in bilayer fluidity. *a*, DOPC; *b*, OPPC; *c*, DOPC/Ch, 4/1; *d*, OPPC/Ch, 4/1; *e*, DOPC/Ch, 2/1; *f*, OPPC/Ch, 2/1. ▲, C_4 (150 mM); △, C_4+C_{12}; ●, no alkanol; ■, C_{12} (2 lipid · 1 alkanol).

Nerve-blocking action of alkanols

The local anaesthetic actions of the primary *n*-alkanols were investigated using an *in vitro* preparation of the lateral olfactory tract (LOT) of the guinea pig. This nerve consists of thinly myelinated nerve fibres of uniform size (1–2 μm diameter) which conduct impulses at 6–8 m s^{-1} (refs 11, 12). We chose this for our experiments as it does not possess the layers of connective tissue characteristic of peripheral nerves that may present a barrier to the diffusion of the less soluble alkanols.

A well defined biphasic compound action potential of 1–6 mV amplitude and 1.5 ms duration was recorded along the length of the nerve after a supramaximal stimulus to the anterior end of the LOT[13]. On exposure to butanol or octanol the first indication of the start of nerve block was an increase in both the latency and duration of the compound action potential. Thereafter, the amplitude of the action potential declined progressively and the latency and duration increased still further, until the nerve was completely blocked. For concentrations of butanol and octanol just sufficient to block nerve conduction this sequence of events took about 15 min (Fig. 3). The actions of the long-chain *n*-alkanols (C_{10}–C_{12}) were similar to those of butanol and octanol. The time taken to achieve nerve block increased progressively as the water solubility of the *n*-alkanols diminished, being up to 700 min for dodecanol (Fig. 3). In the absence of anaesthetic the fibres of the LOT conducted normally for periods in excess of 12 h. Conduction block by all the *n*-alkanols up to C_{11} was shown to be reversible. The effect of dodecanol could only be partially reversed even when nerve block was incomplete (Fig. 3*b*). The perfusion times required to remove the *n*-alkanols increased progressively with increasing chain length and decreasing water solubility.

It has been shown that short-chain alkanols (C_2–C_8) block nerve impulse conduction in the squid giant axon by inhibiting the increase in sodium conductance that is associated with the nerve impulse[14]. This also seems the most likely explanation for the action of the alkanols on the LOT, especially as their effects were similar to the action of tetrodotoxin, a specific sodium-channel blocker. However, nerve block would also be predicted if the alcohols acted by an inhibition of the sodium pump[15]. To test this, nerves were exposed to the sodium-pump inhibitor ouabain (10–15 μM)[16]. Low concentrations of ouabain (10 μM) produced a reversible block of the action potential within 20 min. The rate of decline of the action potentials could be accelerated by repetitive stimulation, as one would expect if this effect were due to block of the sodium pump. In contrast, the effects of the alkanols could not be enhanced by repetitive stimulation (not shown). It therefore seems that both short- and long-chain alkanols act directly on the sodium conductance mechanism and not on the sodium pump.

We have already noted that the long-chain and short-chain *n*-alkanols have opposing effects on membrane fluidity (Figs 1, 2), but both block nerve conduction. Thus, there is no direct correlation between the effects of the *n*-alkanols on membrane fluidity or on phase transitions and their ability to block the conduction of nerve impulses. It could, however, be argued that the decrease in fluidity caused by long-chain alkanols (C_{10}–C_{12}) is responsible for their nerve-blocking action[6], and if this were so the anaesthetic action of all the alkanols could still be regarded as the result of perturbations of the membrane lipids. This hypothesis predicts that alkanols which have opposing actions on membrane fluidity and phase transitions should also have antagonistic actions in their local anaesthetic properties[6].

This proposition was tested by studying the interaction between the local anaesthetic actions of butanol and dodecanol in the LOT. Conventional methods of isobolic analysis of drug interaction were not practicable because of the slow time course of the action of dodecanol. Instead, the depressant action of 30 mM butanol on the LOT compound action potential was measured at various times during continuous perfusion of the nerve with a weak suspension of dodecanol (0.2 mM) in artificial cerebrospinal fluid (CSF). If the actions of the two alkanols were

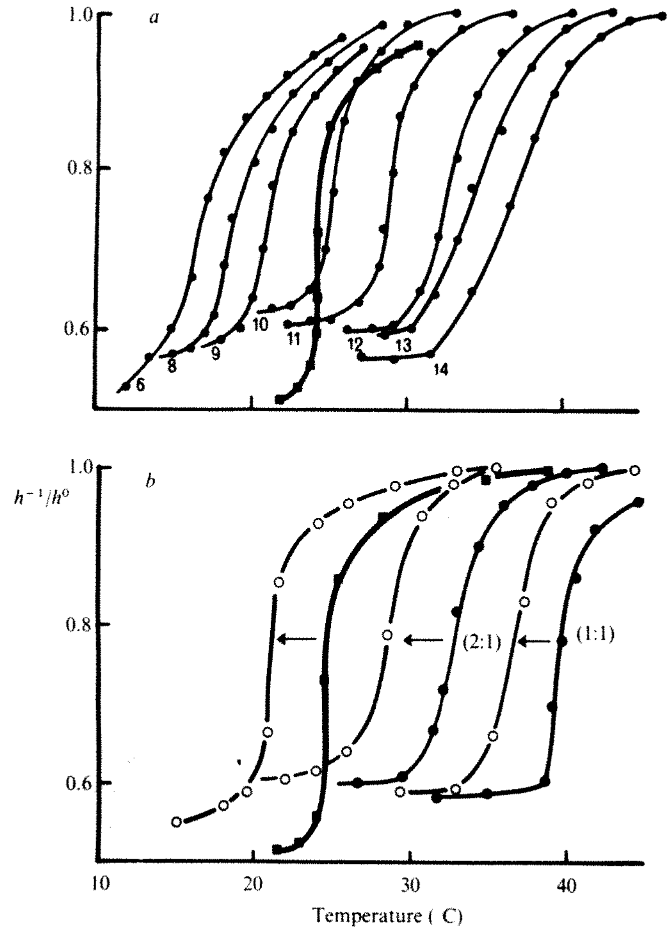

Fig. 2 *a*, The effects of *n*-alkanols on the phase transition of dimyristoyl phosphatidylcholine (DMPC). The phase transition of an aqueous suspension of pure DMPC is shown by the thick line and solid square symbols. All the other curves refer to the phase transition in the presence of alcohols; the chain length is given at the foot of each curve. The alkanols were added either as an aqueous suspension in phosphate buffer to the dried-down lipid samples with the spin label 4′,4′-dimethylaxazolidine derivative of 16-ketostearic acid as in the legend to Fig. 1, or were mixed directly with the lipid in chloroform before drying down. The final alkanol concentrations were 80 mM to C_9 or 50 mM for C_{10}–C_{14}, and the DMPC concentration was 100 mM. *b*, The effect of butanol (C_4, ○, 150 mM) and dodecanol (C_{12}, ●) on the phase transition of DMPC separately and in combination (DMPC:C_{12} at 1:1 or 2:1 molar ratios). As in *a* the DMPC phase transition curve (■) is depressed by butanol and raised by dodecanol. Butanol antagonism (arrows) of the elevation of the phase transition by dodecanol is shown for 1:1 and 1:2 ratios of dodecanol to lipid.

antagonistic, the depressant effect of the butanol would be expected to decrease as the nerve took up the dodecanol. However, the effectiveness of butanol increased progressively with the period of exposure of the nerve to dodecanol (Fig. 4) and this increase in potency was apparent long before the depressant action of dodecanol itself became evident. A similar effect, of even slower time course, was seen when a nerve was exposed to tridecanol instead of dodecanol. The increase in the potency of butanol was not attributable to deterioration of the nerve with time, because the effect of repeated applications of 30 mM butanol to nerves superfused only by artificial CSF was essentially constant over 12 h (Fig. 4).

Other chemical agents have been found to antagonise the physical effects of the short-chain alkanols on lipid bilayers and membranes. For example, the alkanols protect red cells from hypotonic haemolysis, whereas the pyridine derivative 4,*N*-ethylaminoethyl,2-methyl,3-hydroxy,5*S*-methyl-thiomethyl pyridine (EMD-21657; Merck Darmstadt) antagonises the anti-haemolytic actions of alkanols and is an effective treatment of alcoholic organic brain syndrome[41]. Although EMD-21657 alone had no effect on the transition temperature of dimyristoyl phosphatidylcholine at up to equimolar concentrations with the lipid, it slightly antagonised the effect of hexanol in lowering the transition temperature of the lipid. However, EMD-21657 consistently potentiated the local anaesthetic action of hexanol on the LOT (Fig. 5) and, by itself,

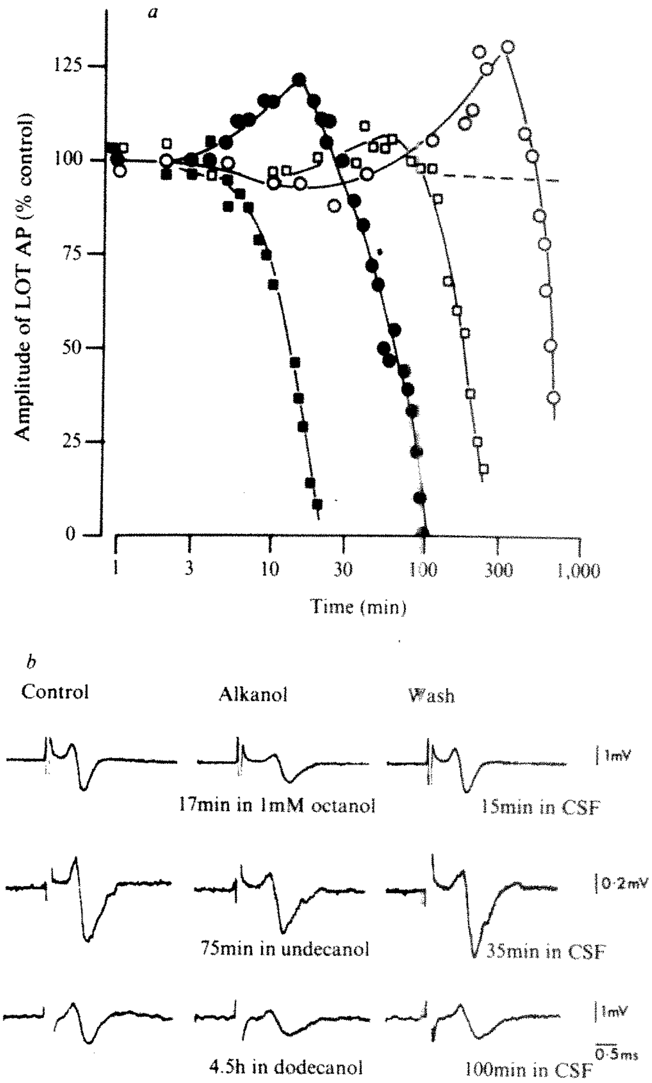

Fig. 3 Local anaesthetic action of primary alkanols. *a*, Time course of action; each alkanol was administered continuously from zero time as a solution or suspension. The ordinate represents the amplitude of the LOT compound action potential expressed as a percentage of its amplitude immediately before the administration of the alkanol. Note logarithmic time scale along abscissa. Results from four separate experiments are shown. Those of a fifth nerve exposed to CSF only are indicated by the broken line (the experimental points were omitted for clarity as were the results for butanol which were essentially similar to those for octanol). ■, C_8; ●, C_{10}; □, C_{11}; ○, C_{12}; ---, CSF. *b*, Sample records from three experiments. As the alkanols affect nerve conduction the action potential becomes smaller and broader, and occurs at a longer latency. This combination of effects is similar for all alkanols and other anaesthetics. Note that the reversal of nerve block by washing with CSF becomes slower with increasing chain length. The details of preparation and incubation have been described previously[38,39]. Octanol was administered as a 1 mM solution in artificial CSF and the long-chain alcohols were administered as suspensions of 1 mM for decanol, 0.5 mM for undecanol and 0.2 mM for dodecanol in CSF. All experiments were carried out at 38 °C with supramaximal stimuli given to the LOT at 0.2 Hz.

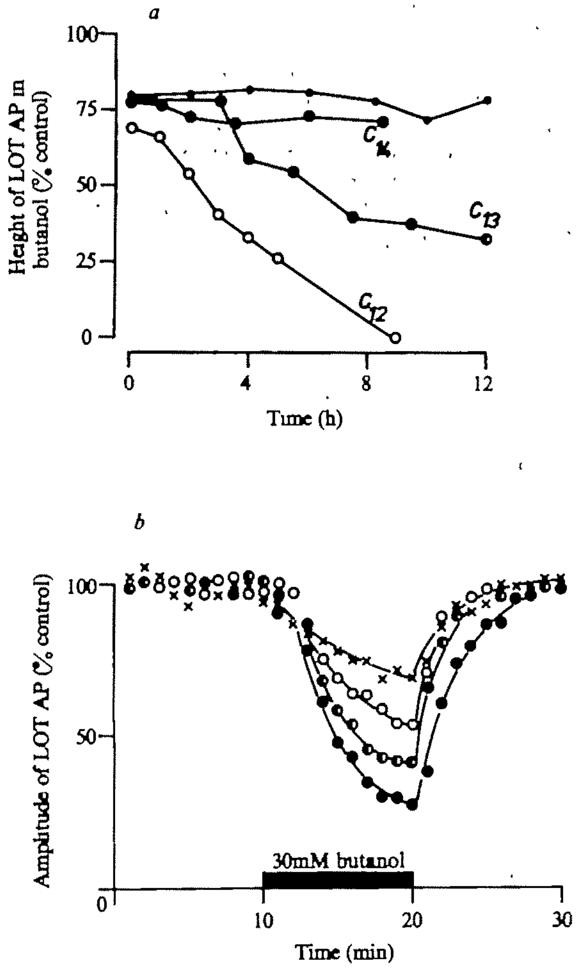

Fig. 4 Interaction between the local anaesthetic actions of butanol and long-chain alkanols (C_{12}–C_{14}). Experimental details as for Fig. 3. *a*, Four representative experiments are shown. Each nerve was exposed to 30 mM butanol for 10 min at various times while a continuous application of one long-chain alkanol was given as indicated. The ordinate represents the amplitude of the LOT action potential (AP) after 10 min exposure to 30 mM butanol expressed as a percentage of the average amplitude for the 5 min before exposure. Dodecanol (0.2 mM) and tridecanol (0.1 mM) were administered as suspensions, tetradecanol was administered at 50 μM in a liposomal suspension (molar ratio of 1:2 with egg yolk lecithin prepared as previously described[28]). ●, No addition; ⊙, C_{14}; ◐, C_{13}; ○, C_{12}. *b*, An example of the potentiating action of dodecanol on the local anaesthetic action of butanol. Initially, the nerve was exposed to 30 mM butanol to determine its sensitivity (X). After washing out the butanol the dodecanol suspension was applied continuously for the remainder of the experiment. At 2 (○), 4 (◐) and 5.5 (●) h, the sensitivity of the nerve to butanol was again determined. The progressive increase in the efficacy of butanol can be clearly seen.

had a small depressant action on the action potential at concentrations up to 5 mM, with little effect on conduction velocity. Similar results have been obtained with the frog sciatic nerve. These results indicate that the local anaesthetic actions of EMD-21657, either alone or with hexanol, cannot be correlated simply with their effects on the physical properties of lipid bilayers.

Temperature effects and unitary hypotheses of local anaesthesia

The interpretation of the effects of temperature on conduction and local anaesthetic action is complicated. The functional properties of the nerve are known to vary with temperature and therefore the sensitivity to perturbation by anaesthetics will be difficult to predict. Cooling the LOT from 38 to 28 °C in the absence of any anaesthetics slowed conduction without a significant reduction in the amplitude of the compound action potential or increase in its threshold. Further cooling slowed conduction still more, decreased the amplitude of the action potential and increased the threshold until at 13–15 °C, cold block occurred. At the same time, the partition coefficient of the anaesthetic in excitable membranes is likely to be changing. For example, the partition of butanol and benzyl alcohol into various lipid bilayers and erythrocyte membranes decreases with cooling (Fig. 6); this is a further complication in predicting how anaesthetic potency will vary with temperature. However, in spite of these complications, the changes in potency of these two local anaesthetics with temperature are inconsistent with any simple unitary hypothesis based on perturbations of the lipid bilayer; suggestions raised include:

(1) Fluidity changes. The fluidity of the lipid bilayer decreases with decreasing temperature and it might be expected that the anaesthetic potency of both alcohols would also decrease, because their fluidising effect would be antagonised by the reduction in temperature (see Fig. 1), and because their concentrations in the membrane would also be reduced. In fact, the potency of benzyl alcohol as a nerve-blocking agent increases with cooling, so that 10 mM benzyl alcohol attenuated the LOT compound action potential by 30–40% at 37 °C, by 60–75% at 27 °C, and by 80–90% at 20 °C (Fig. 6), whereas the potency of butanol decreased slightly over the same temperature range. These marked differences in the effects of butanol and benzyl alcohol with temperature cannot be rationalised simply in terms of an unitary hypothesis based on fluidity perturbations of the lipid bilayer.

(2) Phase separations. Two recent hypotheses propose that anaesthetics act by fluidising regions of phospholipid which are normally in the liquid-crystalline state. Trudell[17] proposed that when this occurs in the lipid bilayer, the lateral pressure the lipid exerts on the target membrane proteins increases and results in the inhibition of their functions and hence anaesthesia. Alternatively, Lee[18] proposed that the proteins responsible for nerve conduction are maintained in an optimal conformation by an annulus of rigid lipid molecules (similar to a liquid-crystalline state) and that anaesthetics fluidise this lipid to cause the protein to relax into an inactive conformation. Both hypotheses predict that cooling a nerve blocked by an anaesthetic should restore conduction. Furthermore, as nerve block is produced by concentrations of alkanols that decrease the T_t of phospholipid bilayers by 3–5 °C, Lee's hypothesis predicts that cooling a nerve by that amount should restore nerve conduction. Both 50 mM butanol and 15 mM benzyl alcohol block conduction in the LOT and produce a decrease in the T_t of phospholipid bilayers of about 3 °C. However, in neither case does cooling by this amount restore nerve conduction (see Fig. 6 and above). Thus,

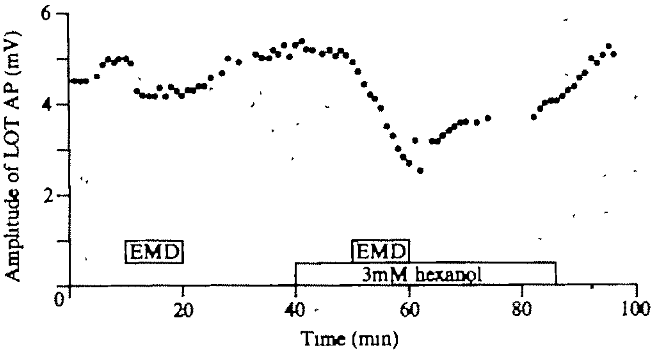

Fig. 5 Interaction between EMD-21657 and hexanol on the amplitude of the LOT compound action potential. EMD-21657 (5 mM) has a slight depressant action but sharply potentiates the action of 3 mM hexanol (3 mM hexanol alone depressed the LOT action potential by 15% in this preparation after 20 min application).

the simplest forms of these two unitary hypotheses are not supported experimentally, and in our view, the wide range of temperatures over which conduction occurs in the LOT and other nerves is a clear indication that perturbation of a critically balanced phase separation is not a likely mechanism of local anaesthetic action. In particular, it is significant that the LOT will conduct at temperatures well above the physiological temperature of 38 °C, at least up to 42 °C, when the annular lipids would be considerably fluidised.

(3) Bilayer thickness. The present data are clearly not directly concerned with the question of changes in bilayer thickness as a mechanism of anaesthetic action, as proposed by Ashcroft *et al.*[19,20] and Haydon *et al.*[15,20]. However, both butanol and benzyl alcohol would be expected to decrease bilayer thickness as they expand the area of red cell membranes[22] and decrease the gel–liquid phase transition temperatures of artificial phospholipid bilayers[23]. This view is consistent with the evidence that anaesthetics decrease the thickness of phospholipid monolayers as their area expands[24,25], but contrasts with the evidence from capacitance measurements on black lipid membranes[19–21]. Even so, we would expect benzyl alcohol and butanol to have similar effects on bilayer thickness and that their potency as local anaesthetics would vary with temperature in the same direction if their primary action were to be on membrane thickness. The fact that this is not observed experimentally suggests that any changes in bilayer thickness that are produced by alcohols will not correlate directly with their local anaesthetic action.

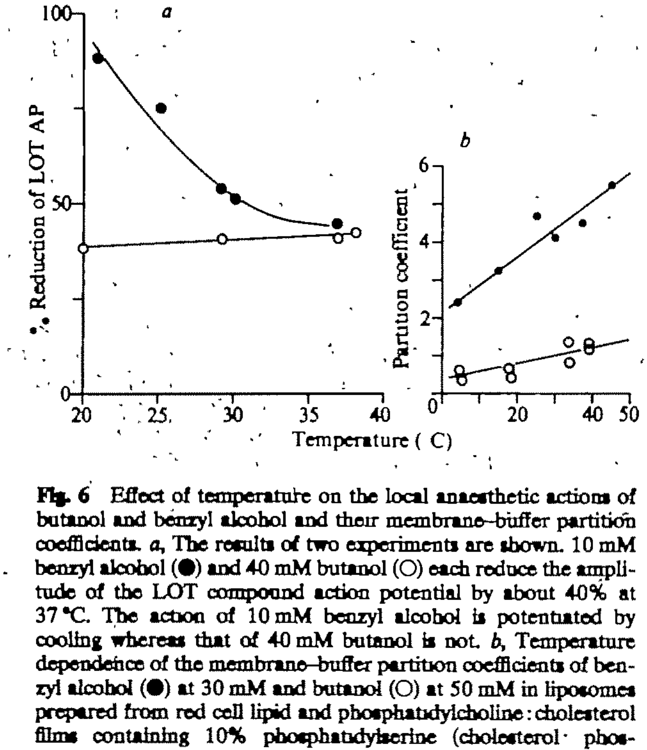

Fig. 6 Effect of temperature on the local anaesthetic actions of butanol and benzyl alcohol and their membrane–buffer partition coefficients. *a*, The results of two experiments are shown. 10 mM benzyl alcohol (●) and 40 mM butanol (○) each reduce the amplitude of the LOT compound action potential by about 40% at 37 °C. The action of 10 mM benzyl alcohol is potentiated by cooling whereas that of 40 mM butanol is not. *b*, Temperature dependence of the membrane–buffer partition coefficients of benzyl alcohol (●) at 30 mM and butanol (○) at 50 mM in liposomes prepared from red cell lipid and phosphatidylcholine : cholesterol films containing 10% phosphatidylserine (cholesterol : phospholipid ratio 1 : 2), respectively. (Data for benzyl alcohol from ref. 40.) The partition coefficients for butanol were determined using equilibrium dialysis with estimation of butanol by gas chromatography.

A degenerate protein perturbation hypothesis

The results presented here show that it is very unlikely that there is a correlation between anaesthetic effects and any of the physical properties of lipid bilayers that have been proposed as the basis of unitary mechanisms of local anaesthetic action. We must therefore conclude that anaesthetics do not generally act by perturbing the lipid bilayer regions of membranes and that direct interactions between the anaesthetic molecules and target membrane proteins are responsible for local anaesthesia. However, we do not imply that all anaesthetics act by binding to a specific site on one or more of the functional membrane proteins; this is extremely unlikely. Instead, we suppose that, for example, small molecules such as halothane or cyclopropane are distributed in one set of hydrophobic sites of appropriate dimensions within the protein, and that larger molecules such as barbiturates, steroids and aromatic amines, which show varying degrees of stereoselectivity[26–29], will bind to distinct sets of sites on the target membrane proteins.

There is some experimental evidence for selectivity in the binding sites of amine local anaesthetics for their action on nerve conduction. For example, their inhibition of the sodium current depends on both the rate of stimulation[30] and the size of the voltage step applied to nerves under voltage clamp[31]. This suggests that they bind to a precise part of the sodium conductance mechanism which must possess the appropriate conformation for binding to occur and which may be located within the channel itself. Finally, we suggest that any molecule with structural features similar to those of phospholipids, such as dodecanol, will compete for the hydrophobic regions of membrane proteins which normally interact with the chains of membrane phospholipids, and that replacing the annular lipids[32] with anaesthetic molecules interferes with the normal lipid–protein interactions that are required for the maintenance of function[33]. The evidence for this type of 'annular displacement mechanism' will be presented elsewhere[34]. Thus, we propose that the binding of anaesthetics to many different sets of sites on the target proteins can inhibit their function and that the mechanism of anaesthetic action is therefore highly degenerate at the molecular level. We term this the degenerate perturbation hypothesis[6,35].

Multiplicity of germline genes specifying a group of related mouse κ chains with implications for the generation of immunoglobulin diversity

Oscar Valbuena, Kenneth B. Marcu, Martin Weigert & Robert P. Perry

Institute for Cancer Research, the Fox Chase Cancer Center, Philadelphia, Pennsylvania 19111

The number of germline genes specifying the variable sequences of the $V_\kappa 21$ group of light chains was determined by saturation hybridisation analysis to be four to six. This gene multiplicity is considerably less than the total variability in the group, indicating that κ-chain diversity is generated by somatic mutations in both framework and complementarity-determining (hypervariable) regions.

THE extensive repertoire of immunoglobulins can be accounted for in two ways: multiplicity of germline variable-region genes (V_L and V_H) and somatic diversification of V genes. In the case of mouse λ light chains, the pattern of variability is simple[1]. Nucleic acid hybridisation and gene-sequencing studies indicate that variability arises somatically by mutation of one germline V_λ gene[2-4]. In contrast, for κ chains, which constitute the bulk of the light chains in the mouse, the pattern of variability is extensive, and can be explained at least in part by multiple germline genes. The V_κ regions fall into various subgroups that are defined by characteristic amino acid residues and shared sequence insertions or deletions[5]. As multiple, identical somatic mutations would be required to produce V_κ regions of two or more subgroups from a single V_κ gene, it has been inferred that different subgroups are coded for by different germline genes. The idea of multiple germline V_κ genes is consistent with the results of nucleic acid hybridisation studies, which indicate that the messenger RNAs coding for unrelated κ chains have little or no homology in their V-region sequences, and that each of these different species of κ-mRNA seems to be coded for by 2–5 genes per haploid genome[6-12].

In this study we assess the extent to which somatic mutation might also contribute to V_κ diversity. We have approached this problem by determining the germline gene multiplicity for a group of related κ chains. This group, called $V_\kappa 21$ according to the recent classification of mouse V_κ sequencies[13], is composed of 30 examples of κ chains produced by independently induced plasmacytomas of either NZB or BALB/c mice (see accompanying paper[14] and ref. 15). The amino-terminal sequences (positions 1–23) of these κ chains are identical except for a single substitution. Throughout the rest of the V region (positions 24–112) there is considerable diversity. Among the 22 NZB examples of $V_\kappa 21$, 20 unique sequences have been found with differences both in the framework and complementarity-determining (hypervariable) regions.

Our estimate of the number of genes coding for selected $V_\kappa 21$-mRNAs indicates that there are only four to six germline V genes for the entire $V_\kappa 21$ group, a value far too small to account for the diversity of this group. This provides a compelling argument for the importance of somatic processes in the generation of κ-chain diversity. Moreover, these results indicate that such somatic processes can result in extensive substitutions in the framework region as well as in the complementarity-determining regions.

Determination of the nucleotide sequence homology among κ-mRNAs

The number of $V_\kappa 21$ genes can be determined by nucleic acid hybridisation measurements with probes containing V-region sequences of selected $V_\kappa 21$-mRNAs. To interpret such measurements correctly, it is necessary to know the capacity of a particular V probe to anneal to various V-region sequences within and outside the $V_\kappa 21$ group. For this reason, we first examined the cross-hybridisation between a labelled complementary DNA representing one member (MOPC 321) with three other selected mRNAs of the group, those coding for PC 3741, PC 7043 and PC 2880 κ chains. These four light chains

Table 1 Cross-hybridisation of full-length MOPC 321 κ-cDNA with κ-mRNAs

mRNA	% protection of full-length MOPC 321 κ-cDNA	% of amino acid homology in the variable region
κ(MOPC 321)	97	100
κ(PC 3741)	98	>94
κ(PC 7043)	98	85
κ(PC 2880)	92	80
κ(MPC 11)	64	~50
C_κ(MPC 11)	68	0
λ(MOPC H2020)	3	
α(MOPC H2020)	3	
None	2	

Hybridisation reactions were carried out at 70 °C in 50-μl reaction mixtures[18] containing 10 ng of mRNA and 0.4–0.5 ng of ^{3}H-cDNA. All mRNAs except C_κ were purified by two cycles of sucrose gradient sedimentation. The C_κ-mRNA was purified by sucrose gradient sedimentation and electrophoresis on a formamide–polyacrylamide gel. The reactions were carried out to a C_rt of 5×10^{-2} mol l^{-1} s and assayed with S_1 nuclease as described previously[18]. The percentages of protection are corrected for 2% self-annealing of the probe at the longest incubation period. The percentages of amino-acid homology in the variable regions refer to the first 98 N-terminal amino acids[14].

differ from each other in the framework as well as the complementarity-determining regions[14]. Relative to MOPC 321 κ chain, the amino-acid sequence homologies in the variable regions of the PC 3741, PC 7043 and PC 2880 κ chains are >94%, 85% and 80%, respectively (Table 1). The variable sequences of MOPC 321 and PC 2880 are among the most distantly related in the $V_κ21$ group. For an example of an unrelated $V_κ$ sequence we used the mRNA coding for MPC 11 κ chain, a member of the $V_κ19$ group, which differs from the MOPC 321 κ chain at 10 of the first 23 N-terminal residues and about half of the total variable-region positions[5,16]. As a control for null hybridisation of V-region sequences we used an mRNA derived from MPC 11 cells ($C_κ$-mRNA), which lacks the sequences coding for the variable region of the κ chain[17].

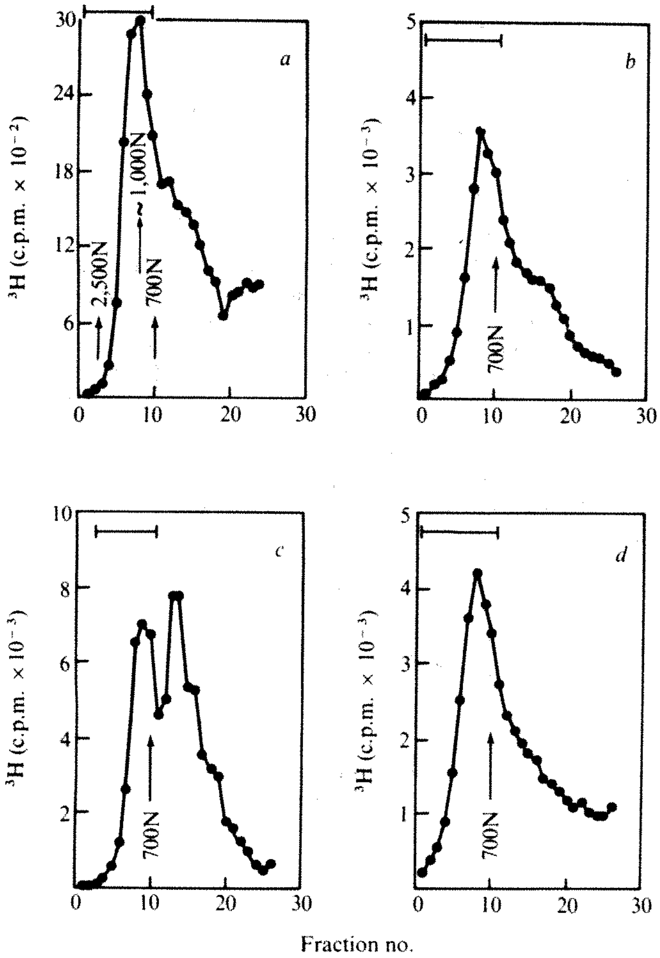

Fig. 1 Isolation of full-length κ-cDNA in alkaline sucrose gradients. 300–500 ng of ^{3}H-cDNAs were sedimented through 5–20% alkaline sucrose gradients in a SW50.1 rotor, at 36,000 r.p.m., at 22 °C for 16 h. Fractions of 200 μl were collected and the radioactivity determined by counting 5–10-μl aliquots in a scintillation counter. Arrows indicate the position of polyoma DNA fragment markers (2,500 and 700 nucleotides (N) long) analysed in parallel gradients. Panels *a–d* show the profiles of the total cDNA preparations synthesised from MOPC 321, PC 2880, PC 3741 and MPC 11 κ-mRNAs, respectively. The fractions corresponding to full-length cDNAs (horizontal bars) were pooled, ethanol precipitated, and used for subsequent hybridisation studies.

The mRNAs used in these experiments were extracted from membrane-bound polyribosomes and purified by oligo dT-cellulose chromatography, sedimentation through successive sucrose gradients and, in some cases, electrophoresis in formamide–polyacrylamide gels[18–20]. Their purity, evaluated by kinetic complexity analysis or oligonucleotide fingerprinting and 5′-terminal analysis, ranged from 75% to close to 100% (refs 18–20). The ^{3}H-cDNAs (10 c.p.m. per pg) were synthesised with avian myeloblastosis virus reverse transcriptase and oligo dT primer in conditions which yield a high proportion of full-length product. Analyses of the cDNAs on alkaline sucrose gradients showed distinct peaks at ~1,000 nucleotides and a trailing of shorter, incomplete transcripts (Fig. 1). To maximise the equivalent representation of 3′ (C region) and 5′ (V region) sequences we used only the cDNA in the fastest sedimenting (1,000-nucleotide peak) fractions. The probes were further purified by back hybridisation to their mRNA templates in conditions in which only the most abundant sequences would anneal[18]. When rehybridised to the mRNA templates at C_rt values of about 10^{-2} or greater, 90–100% of the purified cDNA formed S_1 nuclease-resistant duplex.

When full-length MOPC 321 κ-cDNA was hybridised to κ-mRNAs of MOPC 321, PC 3741, PC 7043 and PC 2880, 97%, 98%, 98% and 92% of the probe, respectively, was incorporated into S_1 nuclease-resistant hybrid (Table 1). The high proportions of MOPC 321 κ-cDNA protected from S_1 nuclease digestion by the heterologous κ-mRNAs indicate that the four mRNAs have a high degree of nucleotide sequence homology. In contrast, the MOPC 321 κ-cDNA probe was not protected by MOPC H2020 λ- or MOPC H2020 α-mRNAs, thus verifying the high specificity of the cDNA preparation. When the MOPC 321 κ-cDNA was hybridised to MPC 11 κ-mRNA or to $C_κ$-mRNA, approximately 65% of the probe was protected. A similar result was obtained when a full-length MPC 11 κ-cDNA probe was annealed to MOPC 321 κ-mRNA (data not shown). This extent of hybridisation is attributable to a common 3′ portion of the mRNA molecules, which contains the coding sequences for the constant regions of the immunoglobulin chains. Assuming that the 3′ untranslated sequences of the κ-mRNAs are identical or very similar for different κ-mRNAs, it seems reasonable to conclude that the additional 30–35% protection exhibited when the other members of the $V_κ21$ group of mRNAs were hybridised to the MOPC 321 κ-cDNA probe represents hybridisation to common variable nucleotide sequences located on the 5′ portions of the mRNA molecules. All the hybrids formed in this analysis had melting temperatures above 90 °C (ref. 19), as one would expect for relatively well matched DNA–RNA duplexes.

The above results indicate that the mRNAs specifying the various members of the $V_κ21$ group have sufficiently similar V-region sequences for their cDNA probes to hybridise effectively to all the $V_κ21$ genes in the reaction conditions used, particularly if complications of sister-strand competition are avoided (see below). On the other hand, a probe representing an unrelated V sequence, such as that corresponding to the variable portion of MPC 11 κ-mRNA, would not be expected to hybridise to a gene of the $V_κ21$ group, and conversely, a $V_κ21$ probe would not be expected to recognise the gene coding for the MPC 11 κ-variable sequence. Previous measurements of cross hybridisation between other $V_κ$ sequences have led to similar conclusions[2,21].

The high degree of homology among $V_κ21$-mRNAs suggests that nucleotide substitutions closely parallel amino-acid substitutions within the $V_κ21$ group. The κ chains of MOPC 321 and PC 2880, the two most distant $V_κ21$ members among those we have investigated, have different amino acids at 20 positions within the first 107 residues from the N-terminal end, which could be accounted for by a minimum of 23 nucleotide substitutions[14]. Assuming no other substitutions in the variable region and identity in the constant and untranslated regions of the mRNA, the minimum nucleotide divergence would be approximately 23/1,000 or 2.3% of the total mRNA sequence. Such a divergence might be manifested by a slight (2–4 °C) difference between the melting temperatures of homologous and heterologous hybrids[12], but it would not be readily detectable by the hybridisation assays used in these experiments. The absence

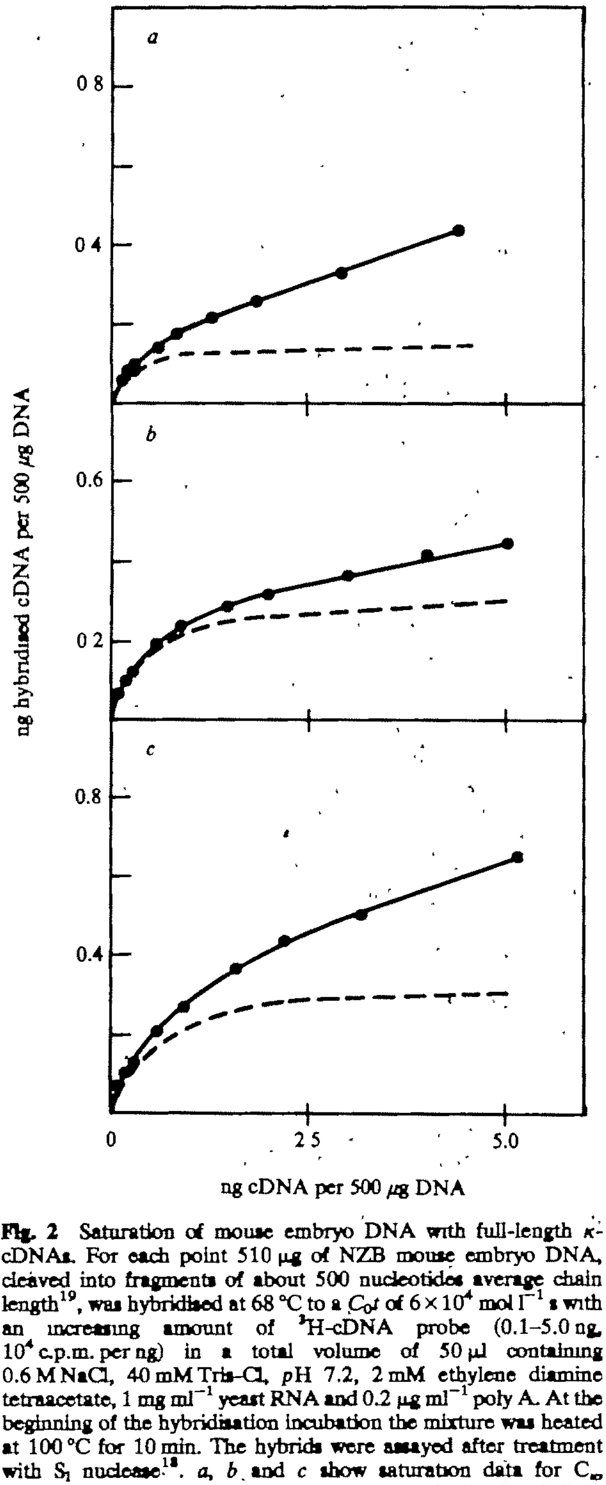

Fig. 2 Saturation of mouse embryo DNA with full-length κ-cDNAs. For each point 510 μg of NZB mouse embryo DNA, cleaved into fragments of about 500 nucleotides average chain length[19], was hybridised at 68 °C to a C_0t of 6×10^4 mol l^{-1} s with an increasing amount of ^{3}H-cDNA probe (0.1–5.0 ng, 10^4 c.p.m. per ng) in a total volume of 50 μl containing 0.6 M NaCl, 40 mM Tris-Cl, pH 7.2, 2 mM ethylene diamine tetraacetate, 1 mg ml^{-1} yeast RNA and 0.2 μg ml^{-1} poly A. At the beginning of the hybridisation incubation the mixture was heated at 100 °C for 10 min. The hybrids were assayed after treatment with S_1 nuclease[18]. *a*, *b* and *c* show saturation data for C_κ, MOPC 321 and PC 2880 κ-cDNAs, respectively. Solid lines represent the hybridised cDNA (corrected for 2% self-annealing of the probes) and broken lines represent hybridised cDNA after correction for contamination (see text). The C_κ-cDNA was prepared by incubating a full-length MOPC 3741 κ-cDNA with the unrelated MPC 11 κ-mRNA and purifying the hybrid by S_1 nuclease digestion. This cDNA consists of constant-region sequences plus untranslated sequences that are common to the PC 3741 and MPC 11 κ-mRNAs.

of cross-hybridisation between the variable sequences of MOPC 321 and MPC 11 κ-mRNAs suggests that between the two sets of corresponding genes there are, in addition to the divergence leading to amino-acid substitutions, substantial differences due to neutral mutations[22-25]. Such a situation is consistent with an evolutionary model in which there is early divergence of the ancestral genes for MOPC 321 and MPC 11 V_κ sequences and a more recent expansion of these individual gene sets.

Estimation of gene number

The gene multiplicity was determined by saturation experiments, in which a fixed amount of mouse embryo DNA was hybridised with increasing amounts of full-length κ-cDNA probes. When the probe is in large excess relative to the corresponding gene sequence, the elimination of reactive loci due to the annealing of (−) DNA sister strands is negligible, and one may expect that all the relevant genes will be duplexed with probe. This feature is particularly advantageous for measuring the aggregate number of closely related genes because it minimises the possibility of related but non-identical sequences being out-competed by perfectly matched (−) DNA strands. As this effect would be magnified when gene sequences are in excess, the validity of immunoglobulin gene copy numbers determined by reassociation kinetic analysis has been questioned[2,26,27].

When 510 μg of embryo DNA was incubated to a C_0t of 6×10^4 mol l^{-1} s with increasing amounts of probe, data such as those shown in Fig. 2 were obtained. The saturation curves were apparently biphasic and did not exhibit true saturation plateaux. The biphasic nature was more clearly revealed when double-reciprocal plots of the saturation data were made (Fig. 3). All the curves consisted of a linear component representing the saturation behaviour of the predominant cDNA species, and a deviation from linearity at high cDNA inputs, which is most readily interpreted as representing the hybridisation of a small, but diverse fraction of contaminating non-κ-chain sequences, each of which is present in subsaturating amounts. This interpretation was substantiated by several facts. First, when the input of MOPC 321 κ-cDNA was 12.5 ng (2.5 times the highest input used in Fig. 2), the saturation curve still failed to approach a plateau, and, in fact, continued to rise with constant slope. Second, the levels of putative contaminating non-κ-chain sequences in the MOPC 321 and MPC 11 cDNA probes calculated from the reciprocal plot analysis (3% and 9%, respectively, see below) are roughly proportional to the levels of impurities in the respective mRNA preparations, as judged from kinetic complexity analyses[18]. Third, when saturation experiments were carried out with homogeneous κ-mRNA sequences prepared from cloned DNA, true saturation plateaux and completely linear reciprocal plots were observed (Fig. 4). Moreover, the gene numbers estimated from these saturation values did not differ significantly from the corresponding numbers obtained with enzymatically synthesised probes when corrections for the contaminating components had been made (see below).

To calculate the saturation values corresponding to each κ-chain species, we empirically assigned a percentage of contamination to each probe, which if corrected for, would result in a completely linear curve in the reciprocal plot (Fig. 3). The levels of contamination estimated by trial and error were 2.9%, 6.5%, 6.5% and 9.0% for MOPC 321 κ-cDNA, PC 2880 κ-cDNA, C_κ-cDNA and MPC 11 κ-cDNA, respectively. When these proportions of nonsaturating components were subtracted from the hybridisation values, reasonably good plateaux were obtained (broken curves, Fig. 2). The saturation values (H_∞) were then calculated from the corrected ordinate intercepts of the double-reciprocal plots (Fig. 3). The high precision of the saturation data enabled us to calculate the H_∞ values with a maximum probable error of ±10%. These values, together with the molecular weight of the mouse haploid genome and the molecular weights of the C_κ and V_κ segments, were used to calculate the number of gene copies (Table 2). One set of gene numbers was calculated using 650 nucleotides and 350 nucleotides, respectively, for the C_κ and V_κ molecular weights, based on the fact that about 65% of full-length MOPC 321 κ-cDNA (1,000 nucleotides) is protected by MPC 11 κ-mRNA or C_κ-

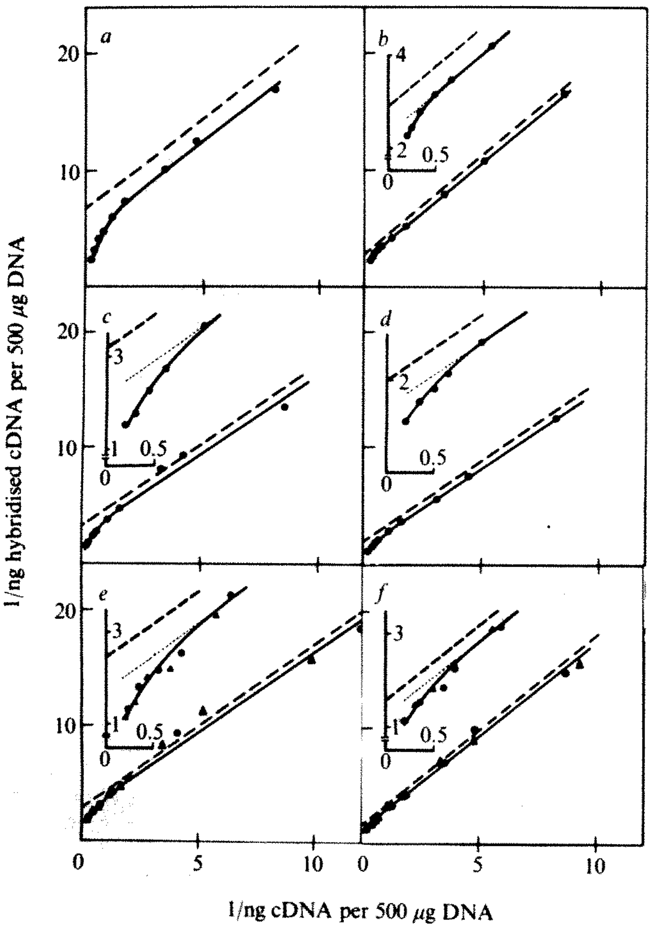

Fig. 3 Double-reciprocal plots of the cDNA saturation data. Solid lines represent hybridised cDNA (2% self-annealing subtracted). Broken lines represent hybridised cDNA after correction for contamination of probe by non-κ-chain sequences. The intercept and slope of the broken lines were estimated by the least squares method. *a–d* correspond to C_κ, κ(MOPC 321), κ(PC 2880) and κ(MPC 11) cDNA saturation reactions, respectively. *e* and *f* correspond to equimolar mixtures of κ(MOPC 321)+κ(PC 2880) and κ(MOPC 321)+κ(MPC 11) cDNAs, respectively. ▲ and ● refer to two independent experiments. Contaminant correction for the mixtures was made using an average for the individual probes. The portions of the curves with the higher cDNA inputs are enlarged in the insets.

mRNA sequences (Table 1). An alternative set of gene numbers was calculated using 521 and 479 nucleotides, respectively, for the C_κ and V_κ segments, based on current ideas of the structure of a κ-mRNA[28]. With this information, the calculated gene multiplicities per haploid genome are as follows: 2–3 genes for C_κ; 4–6 V_κ genes for MOPC 321; 4–5 V_κ genes for PC 2880; 8–11 V_κ genes for MPC-11. It is evident that all the tested V_κ genes are in a higher number of copies than the C_κ gene.

When a 1:1 mixture of MOPC 321 and MPC 11 κ-cDNAs was used, the measured number of V_κ genes is in good agreement with the sum of the individual gene reiteration values. On the other hand, when a mixture of MOPC 321+PC 2880 κ-cDNAs was used, no additive hybridisation was observed; the measured number of V_κ genes for this mixture is not significantly different from either of the individual V_κ-gene reiteration values for MOPC 321 or PC 2880. These results support the inferences made on the basis of the cross-hybridisation experiments. The additivity exhibited by MOPC 321 and MPC 11 V_κ sequences demonstrates that the two probes are hybridising to separate genetic loci, thus implying two different sets of genes. The non-additivity displayed by MOPC 321 and PC 2880 V_κ sequences indicates that both probes are hybridising to the same 4–6 V_κ21-related loci.

The saturation data with the cloned DNA sequences were also used to calculate gene numbers. In this case, estimates of the sizes of the C_κ and V_κ segments were made from measurements of the amounts of cloned MPC 11 κ-DNA sequence protected by MOPC 321 κ-mRNA (70%) and MPC 11 κ-mRNA (100%). As the cloned MPC 11-κ-sequence was calculated to be 700 nucleotides (U. Schibler, personal communication), 70% or 490 nucleotides of the probe represent C_κ sequences and 30% or 210 nucleotides represent V_κ sequences. With these parameters, gene copy numbers of 2 and 8 per haploid genome for C_κ and MPC 11-related V_κ genes were calculated (Table 2). These values are in excellent agreement with the values obtained with enzymatically synthesised cDNAs after corrections for the non-κ-chain contaminants had been made, thus indicating that such corrections do not contribute significant errors to our estimates of gene number.

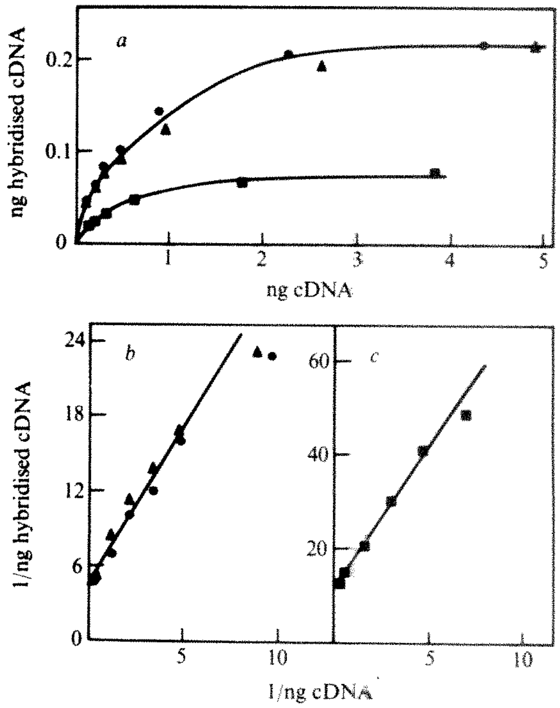

Fig. 4 Saturation–hybridisation reactions with cloned MPC 11 ^{125}I-κ-cDNAs. The cloned MPC 11 κ-mRNA sequence is carried as a 700-nucleotide insert in the plasmid pMB9. The recombinant DNA was iodinated to a specific activity of 60 c.p.m. per pg, denatured and hybridised in 80% formamide for 1 h at 50°C to an excess of MPC 11 κ-mRNA. The hybridisation mixture was treated with S_1 nuclease, and the ^{125}I-κ-DNA sequences recovered and submitted to a second round of purification by hybridisation with either MPC 11 κ-mRNA or MOPC 321 κ-mRNA and subsequent treatment with S_1 nuclease[19]. The resultant homogeneous probes represent C-plus-V-region sequences or predominantly C-region sequences, respectively. 0.448 mg of mouse embryo DNA was hybridised to increasing amounts of cloned probes (0.1–5.0 μg) in a total volume of 50 μl. The reactions were incubated and assayed as described in Fig. 2. The final C_0t value in this set of reactions was 5.4×10^4 mol l^{-1} s. *a*, Saturation curves for MPC 11 κ-DNA (▲ and ● refer to two independent experiments) and for C_κ-DNA (■). The hybridisation values were corrected for self-annealing (6% for MPC 11 κ-DNA and 15% for C_κ-DNA). *b*, *c*, Double-reciprocal plots of the MPC 11 κ-DNA and C_κ-DNA saturation curves, respectively.

The basis of $V_\kappa 21$ diversity

The $V_\kappa 21$ group of immunoglobulins is apparently represented in germline DNA by four to six genes specifying the variable-region sequences. These same four to six genes are recognised by sequence probes corresponding to any member of the group, even variants such as MOPC 321 and PC 2880 which must differ, as inferred from their amino acid sequences, by at least 7% of the nucleotides in the V-region sequence. In contrast, amino-acid sequence studies[14,15] have revealed extensive diversity in the $V_\kappa 21$ chains; if only the NZB $V_\kappa 21$ sequences are compared (to preclude any contribution of genetic polymorphism), 20 different sequences are found in the region 1–112. From the pattern of variability, $V_\kappa 21$ may be subdivided into six subgroups, $V_\kappa 21$ A to F, on the basis of two or more $V_\kappa 21$ regions sharing at least three residues that distinguish members of a particular set of $V_\kappa 21$ sequences from any other $V_\kappa 21$ sequence. The sequences that define $V_\kappa 21$A–F extend only to residue 98; the rest of what has conventionally been called V_L gene (to residue 112) shows a distinctive pattern of variability that is independent of the pattern over 1–98. It has been proposed that $V_\kappa 21$ is coded for by at least six germline genes coding for residues 1–98 or 99. The rest of the V region (99 or 100 to 112) is coded for by a separate set of genes, termed J genes. This view of $V_\kappa 21$ gene organisation is analogous to that recently proposed for the mouse λ gene[4,29].

Table 2 Gene copy numbers estimated from saturation–hybridisation experiments

cDNA	H_∞	$n(a)$	$n(b)$	$n(c)$
Constant genes				
C_k	0.15	2.4	3.0	
cloned C_k	0.08			2.0
Variable genes				
κ(MOPC 321)	0.35	6.1	4.4	
κ(PC 2880)	0.31	4.9	3.6	
κ(MPC 11)	0.49	10.6	7.7	
cloned κ(MPC 11)	0.22			8.1
κ(MOPC 321)+κ(PC 2880)	0.34	5.9	4.3	
κ(MOPC 321)+κ(MPC 11)	0 63	14.9	10.8	

H_∞ is the mass of cDNA (in ng) hybridised at infinite input, obtained from the ordinate intercepts of Fig. 3. The number of genes, n, is calculated assuming that the probes contain C_κ and V_κ sequences, respectively, comprising: a, 650 and 350 nucleotides; b, 520 and 480 nucleotides; c, 490 and 210 nucleotides. For constant genes, $n = (H_\infty^C \times MW_g)/(A \times MW_C)$. For variable genes, $n = (H_\infty^{V+C} - H_\infty^C)MW_g/(A \times MW_V))$. H_∞^C and H_∞^{V+C} are the H values for the C and C+V probes, respectively. MW_g, MW_C and MW_V are the molecular weights of the mouse genome ($1\ 8 \times 10^{12}$), the C_κ and the V_κ sequences, respectively. A is the mass of mouse embryo DNA per reaction (0.45 or 0.51 mg).

The estimate of six germline $V_\kappa 21$ genes based on shared amino-acid sequences is consistent with our finding that $V_\kappa 21$ is represented by at most six germline genes. The additional diversity in $V_\kappa 21$, over and above that due to multiple $V_\kappa 21$ genes, must be due to somatic diversification. It is plausible that one source of such diversification is joining of different $V_\kappa 21$ genes with different J genes. So far, amino-acid sequencing data suggest that such a process involves only two gene segments. However, $V_\kappa 21$ examples might still be found with other identical amino-acid substitutions which would define new subgroups. In this case, additional J-type segments would need to be invoked[30].

Extensive diversity is also observed in comparisons of $V_\kappa 21$ sequences in the region 1–98. Most of the sequence differences occur in the complementarity-determining regions. In this sense the pattern of variability is similar to that found in mouse V_λ, in which variability is confined to the complementarity-determining regions[1]. That the observed variability is concentrated in these regions could be due to somatic mutation and selection by antigen of mutants with appropriate specificities. In contrast to V_λ, however, variability in the 1–98 region of $V_\kappa 21$ is also seen outside the complementarity-determining regions, that is, in the framework regions. The 10 different framework sequences seen in the limited survey already exceeds the six that we can account for by different germline genes. That somatic variation is observed in the framework portions could imply that variation in the framework can also serve to modify antibody specificity. Alternatively, somatically derived variation both in the complementarity-determining and framework regions might reflect features of the rate or specificity of the somatic process.

The degree to which somatic diversification contributes to total V_κ-chain diversity can be assessed from our method for counting germline genes. We have shown that four to six germline genes code for $V_\kappa 21$ and about eight code for an unrelated group represented by the MPC 11 κ chain. Similar values have been obtained for the MOPC 21 κ chain, a member of the $V_\kappa 15$ group, which is unrelated to either the $V_\kappa 21$ examples or MPC 11 (ref. 12). If each V_κ group is coded for by four to eight genes, then the total germline gene content for V_κ will be four to eight times the number of such unrelated V_κ groups. This latter value has been estimated to be about 50, based on the repeat frequency of identical sequences in the region 1–23 found in a group of randomly chosen NZB κ chains[1]. Hence, the total number of V_κ germline genes can be estimated to be about 300. If the germline gene content for V_H is correspondingly high, then the potential germline repertoire of antibody specificities could be of the order of 10^5. This value, although large, still falls short of the estimated repertoire ($>10^6$) that an inbred mouse seems to express[26]. Hence, somatic diversification, as shown here for $V_\kappa 21$, must also be responsible for producing most antibody specificities.

This research was supported by a grant from the NSF, grants from the NIH and an appropriation from the Commonwealth of Pennsylvania. O.V. is the recipient of a fellowship from the Venezuelan government. The cloned MPC 11 κ-mRNA sequence was provided by Dr Ueli Schibler.

Rearrangement of genetic information may produce immunoglobulin diversity

M. Weigert & L. Gatmaitan

The nearly complete amino-acid sequences of 22 closely related immunoglobulin κ variable (V_κ) regions from the inbred NZB mouse are presented. This group of V_κ regions is encoded by at least six germline V_κ genes. These data also suggest that the mouse κ gene is divided into three segments termed V or variable (residues 1 to 98 or 99), J or joining (residues 99 or 100 to 112) and C or constant (residues 113–219). Tonegawa et al. *have recently described a similar J segment for mouse λ chains. Inbred mice contain multiple V_κ and J_κ gene segments. Therefore, different combinations of V and J gene segments may be joined at the DNA level during the differentiation of individual lymphocytes to contribute to antibody diversity.*

RECENT structural studies on antibody molecules, mRNAs and genes have contributed substantially to our understanding of antibody diversity. Antibody polypeptides are divided into two regions, an N-terminal variable (V) region and a C-terminal constant (C) region. The organisation of antibody genes seems unusual in two respects: (1) the V and C regions are encoded by separate genes in the germline of each organism[1,2] and (2) these genes are rearranged with respect to one another during the differentiation of the antibody-producing cell[3,4]. Variable regions, which encode the antigen-binding sites, are the focus for three theories of antibody diversity. The germline theory contends that antibody variability is encoded by large numbers of germline V genes[5]. The somatic mutation theory postulates that diversity arises by somatic variation of relatively few germline genes[6]. A third model suggests that the rearrangement of antibody gene segments during differentiation may also generate antibody variability[7–9]. The studies described here on mouse κ chains stress the importance of multiple germline V genes and suggest that antibody diversity may be increased by the combinatorial joining of multiple V and J gene segments.

Diversity in mouse light chains

Myeloma tumours artificially induced in two inbred strains of mice, BALB/c and NZB, have provided homogeneous immunoglobulins, mRNAs and chromosomal DNA for the analysis of the diversity patterns of V regions in the two light-chain immunoglobulin families, λ and κ[10]. The overall pattern of V-region diversity in mouse light chains shows that most of the variability resides in three hypervariable regions. These fold to constitute the light-chain contribution to the walls of the antigen-binding crevice. The remainder of the V region provides a scaffold for the binding site and is termed the framework region[7,11–13]. The extent and nature of diversity patterns in V_λ and V_κ are quite different.

The sequences of mouse λ chains suggest that somatic mutation may have an important role in generating antibody diversity. Amino acid sequence analyses have established that 12 of 18 V_λ regions studied are identical and that the remaining six differ by one to three amino acid substitutions, all of which occur in one of three hypervariable regions[15]. It has been proposed that the 12 identical V_λ regions ($V_{\lambda 0}$) are encoded by a single germline gene and that the variants arise by somatic mutations[6]. This interpretation is supported by nucleic acid hybridisation studies which suggest that V_λ regions are encoded by one or a few germline genes[16,17]. In addition, the DNA sequence of the putative germline V_λ gene, $V_{\lambda 0}$, has been determined for a V_λ gene isolated from presumably undifferentiated mouse embryo DNA and a variant sequence has been determined on another V_λ gene isolated from myeloma DNA[18]. (A 19th λ chain, MOPC 315, seems to differ by about 10% of its V sequence from the other 18 λ chains. This V region is probably encoded by a second V_λ gene.) Thus, most mouse λ chains exhibit a simple pattern of diversity at the protein and nucleic acid levels that is consistent with one germline V gene and variants arising by somatic mutations.

Variability in mouse V_κ regions is extensive in both hypervariable and framework regions[11,19]. A relatedness tree for the N-terminal 23 residues, a portion of the framework region, of 61 BALB/c and NZB κ chains depicts 55 different sequences (Fig. 1). We will refer to a set of V_κ regions which are very similar over their N-terminal 23 residues as a group. (Potter has suggested that each set of mouse V_k regions differing by three or fewer residues at their N terminus be given number (that is, group) designations[20]. By his criterion, 64 BALB/c V_κ sequences fall into 26 groups and 31 NZB V_κ sequences fall into 14 groups.) The complete V-region sequences from distinct groups may differ by up to 50% of their sequence. The genetic interpretation of V-region groups is that each is encoded by at least one distinct germline V gene because multiple, identical somatic mutations would be required to produce the immunoglobulin V regions of two or more groups from a single V_κ gene[21,22]. This is described as the argument of parallel mutation.

Nucleic acid hybridisation data support the supposition that different groups are encoded by distinct V genes[23]. Hence, the minimum number of germline genes in a particular antibody family can be estimated by counting V-region groups. In the mouse κ family, the number of groups has been estimated to be about 50 for either BALB/c or NZB mice[15]. If the myeloma data analysed do not constitute a random selection of the normal V_κ genes, the number of groups could be larger. In striking contrast, most λ chains fall into a single group.

The variability of mouse κ chains within a single group, $V_\kappa 21$, does not resemble that of the predominant λ group (for example, with variability only in hypervariable regions). This has been shown for eight BALB/c κ chains in the V_κ 21 group that have identical N-terminal sequences except for a single substitution. Three pairs of these V_κ regions fall into closely related sets or subgroups, designated $V_\kappa 21A$, $V_\kappa 21B$ and $V_\kappa 21C$, which are defined by multiple shared or subgroup-associated amino acid residues. The remaining two V regions differ from V_κ regions of the three subgroups and from each other[24,25]. This survey suggests that the $V_\kappa 21$ group in BALB/c mice is coded for by at

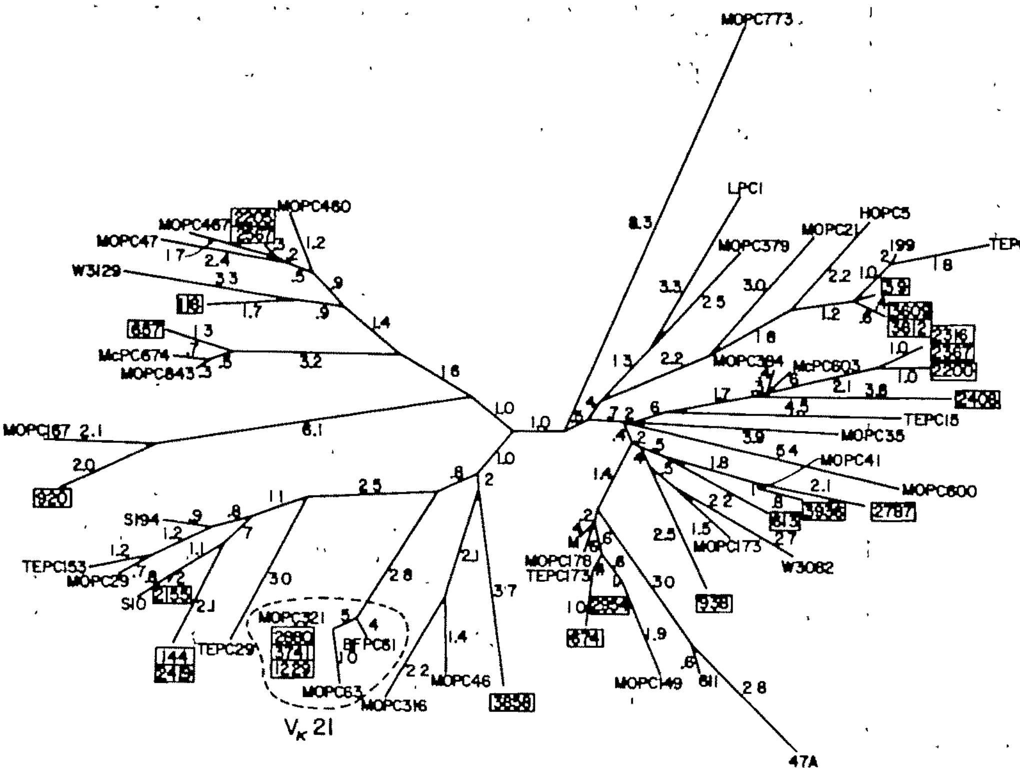

Fig. 1 A relatedness tree for N-terminal 23 residues of 55 different V_κ sequences of the mouse. These V_κ regions are derived from NZB (boxed) and BALB/c mice. The $V_\kappa21$ group is indicated by a dotted circle. The numbers on the lines indicate the number of nucleotide substitutions that separate two successive junction (node) points on the tree. Thus, the minimal extent to which individual κ chains differ from one another at the nucleotide level can be determined by summing the lengths of the lines between the two V_κ regions (adapted from ref. 19)

least three germline V genes by the argument of parallel mutation.

The object of this study is to analyse further the extent and pattern of diversity in the $V_\kappa21$ group of NZB mice. In a screen of the N-terminal sequences of 31 NZB κ chains, three $V_\kappa21$ chains, PC3741, PC2880 and PC1229, were found[26]. Using the NZB κ chains, PC3741 and PC2880, or the BALB/c $V_\kappa21$ chains, T124 and M70, antisera were made which specifically identify $V_\kappa21$ chains and distinguish a set reacting with antisera to PC2880 or M70 from a second set reacting with antisera to PC3741 or T124 (Fig. 2). Of 700 NZB myeloma immunoglobulins screened with these antisera, 5.7% fell into the first set and 3.1% into the second. In addition, the normal light chains from the sera of several inbred strains of mice crossreact with these antisera to levels of 7.2% and 1·4%, respectively.[27] Thus, the $V_\kappa21$ group constitutes about 8–9% of normal serum and myeloma light chains. This group is an ideal model system for studying the nature of diversity within the κ family of the mouse because many members of the $V_\kappa21$ group can be readily identified by rapid serological assays. Furthermore, the high frequency of these κ chains in normal sera suggests that the $V_\kappa21$ light chains are used not only in myeloma antibodies, but also in normal antibodies. In this article we report on the V-region sequences of 22 NZB κ chains belonging to the $V_\kappa21$ group. These data suggest that the $V_\kappa21$ group is encoded by multiple germline genes and that the V region is encoded by two separate DNA segments, V and J.

$V_\kappa21$ regions fall into six subgroups

Twenty-two NZB $V_\kappa21$ regions are compared. A summary of the methodology used to sequence these V regions is given in the legend to Fig. 2 and the complete data will be presented in detail elsewhere[28–30]. Of these $V_\kappa21$ regions, 18 fall into six subgroups, denoted by $V_\kappa21$A, B, C, D, E and F, in which two or more closely related V_κ regions share at least three subgroup-associated residues. Subgroup-associated residues distinguish the members of a particular subgroup from members of most of the other subgroups (boxed residues in Fig. 2); 29 subgroup-associated residues occur in positions 1–98. Variable regions from different subgroups differ from one another by 3 to 20 residues over their N-terminal 98 residues (Fig. 3). The reason for limiting our subgroup analysis to the N-terminal 98 residues will become apparent later. Again, even closely related subgroups (such as $V_\kappa21$E and $V_\kappa21$F) seem to be encoded by separate germline V genes by the argument of parallel mutation, namely, that it is unlikely that somatic mutation could generate in two or more independent lymphocyte lineages the three identical substitutions that separate V_κ regions of these two subgroups. Thus, at least one distinct germline V gene seems to encode each of the six subgroups (Fig. 3).

The minimal number of six $V_\kappa21$ germline genes deduced from V region amino acid sequences is larger than the one to three $V_\kappa21$ deduced from nucleic acid hybridisation experiments[31]. However, saturation-hybridisation studies using DNA probes derived from several $V_\kappa21$ mRNAs suggest that four to six germline genes encode the $V_\kappa21$ regions (see accompanying paper[32]). This number is consistent with the number of V genes we have identified so far by subgroup analysis.

It is possible that additional $V_\kappa21$ subgroups will be found. Four of the NZB $V_\kappa21$ regions (that is, PC2154, PC2413, PC7461 and PC2960) do not fall into any of the six subgroups and are indicated as distinct branches on the relatedness tree (Fig. 3). These V regions cannot yet be designated separate subgroups because a similar reasoning is needed to invoke the argument that separate germline genes for each subgroup avoid multiple identical somatic mutations (see above). If new $V_\kappa21$ sequences are found which pair with these examples, additional $V_\kappa21$ subgroups would be defined. In addition, currently defined subgroups may split into two or more new subgroups. For example, PC2485 was a member of the $V_\kappa21$E subgroup until the sequence of PC4039 was determined. These two identical sequences then became subgroup $V_\kappa21$F, sharing three distinct subgroup-associated residues (Fig. 2).

If additional $V_\kappa21$ subgroups are defined, then two possibilities must be considered. The saturation-hybridisation experiments have underestimated the number of $V_\kappa21$ genes. Alternatively, a somatic mechanism may exist which permits a single germline V gene to generate two or more subgroups of $V_\kappa21$ regions.

Genetic rearrangement during differentiation

The $V_\kappa21$ regions seem to have two distinct segments which we have designated the V segment (residues 1 to 98 or 99) and the J segment (residues 99–112). With this nomenclature, we can distinguish the V segment from the classical V region (residues 1–112).

The N- and C-terminal boundaries of the V and J segments are defined as follows. The J segment seems to have started by position 101 because of the invariant association of a leucine at this position with an alanine and leucine at positions 105 and 111, respectively, in the J segment of six different V$_\kappa$21 regions (Fig. 2). This repeated invariant association of three residues suggests that positions 101–111 behave as a discrete genetic unit. The last subgroup-associated residue of the V segment is at position 98. Accordingly, the N-terminal boundary of the J segment may start somewhere between residues 99 and 101. Position 100 is an amino acid insertion in one κ chain (PC7132) and we have arbitrarily chosen the J segment to include this position, suggesting that the extra residue comes from a J segment one residue longer than the others. The C-terminal boundary of the J segment occurs at position 112, the C-terminal-most variable residue in κ chains (Fig. 2. PC2413). Moreover, as the C region seems to be encoded by one or a few C genes[17,32–34], the variability in the J region is too great to be accounted for by multiple C$_\kappa$ genes beginning at position 100.

The V and J segments associate independently with one another (Fig. 4). In the 18 V$_\kappa$21 regions with relatively complete sequence data between residues 100 and 112, there are 16 different V segments and eight different J segments (Fig. 2). A particular J segment may be associated with V$_\kappa$ segments from four different subgroups (sequence 5 in Fig. 4). Conversely, identical V segments may be associated with different J segments (for example, PC6684 and PC7175, PC7043 and PC7183, and PC4050 and PC9245). The implication is that the V and J segments associate freely with one another and that particular V segments are not generally associated with certain J segments (Fig. 4). Indeed, some of these same J segments are associated with non-V$_\kappa$21 V segments of widely differing sequence[11]. Thus, a particular J segment of the κ family may be capable of associating with any V segment of the κ family.

Nucleic acid studies on mouse λ and κ genes also suggest that there are V and J segments. Two mouse V$_\lambda$ genes isolated from embryonic DNA terminate their V genes at a position homologous to residue 101 (refs 2, 18). In addition, a J$_\lambda$ segment consisting of approximately 36 nucleotides and separated from the V$_\lambda$ segment by intervening DNA sequences has been described[4]. Thus, the mouse λ-gene family also seems to be composed of V, J and C segments. Several mouse V$_\kappa$ genes isolated from myeloma DNA also terminate at approximately position 101 (ref. 35). These DNA studies taken together with our V$_\kappa$21 sequence data suggest that the κ-gene gamily has two important organisational features (Fig. 5): (1) The κ chain is encoded by three noncontinuous gene segments, V, J and C; (2) multiple V-gene and J-gene segments are present in the κ-gene family of each mouse.

The most attractive function for the J segment is that it may be involved in generating antibody diversity. Residues 100 and 101 constitute a portion of the third hypervariable region[14]. Accordingly, if the J segment occurs at positions 100–112, a

Fig. 2 The amino-acid sequences of V regions from the mouse V$_\kappa$21 group. The sequences are divided into subgroups which are designated V$_\kappa$21A–V$_\kappa$21F. Additional potential subgroups are indicated with question marks. The T111 sequence is a BALB/c protein[25], identical to PC3741, which permits the definition of subgroup V$_\kappa$21C. The subgroup-associated residues unique to three or fewer subgroups are boxed. The intra-subset substitutions are circled. Amino-acid compositional data are indicated by brackets. The three hypervariable regions are indicated as hv1, hv2 and hv3. The J segment extends along residues 100–112. The serological crossreactivity of individual proteins to antisera directed against two screening κ chains is given on the right. The following general strategy was used for sequencing these V regions. The intact light chain was analysed on the automatic sequenator for 40 residues. The procedures for automatic sequence analysis are given in ref. 28 where the data for a 78-residue run on PC4050 are presented. Methionine fragments were prepared; all V$_\kappa$ regions but one have a methionine at position 37. Methionine fragments starting at position 38 sequenced for 40–65 residues. Only the V$_\kappa$21A subset has additional methionine residues and these fragments were isolated and sequenced. In certain cases mild acid cleavage was used to split aspartic acid–proline bonds. Arginine fragments extending over positions 65–113 were prepared for certain κ chains and sequenced for 35–40 residues. Thermolysin, tryptic and chymotryptic peptides were isolated from certain of these methionine or arginine fragments and compositions were determined. In some cases these peptides were sequenced in the presence of polybrene. A detailed analysis of these data will be presented elsewhere[28].

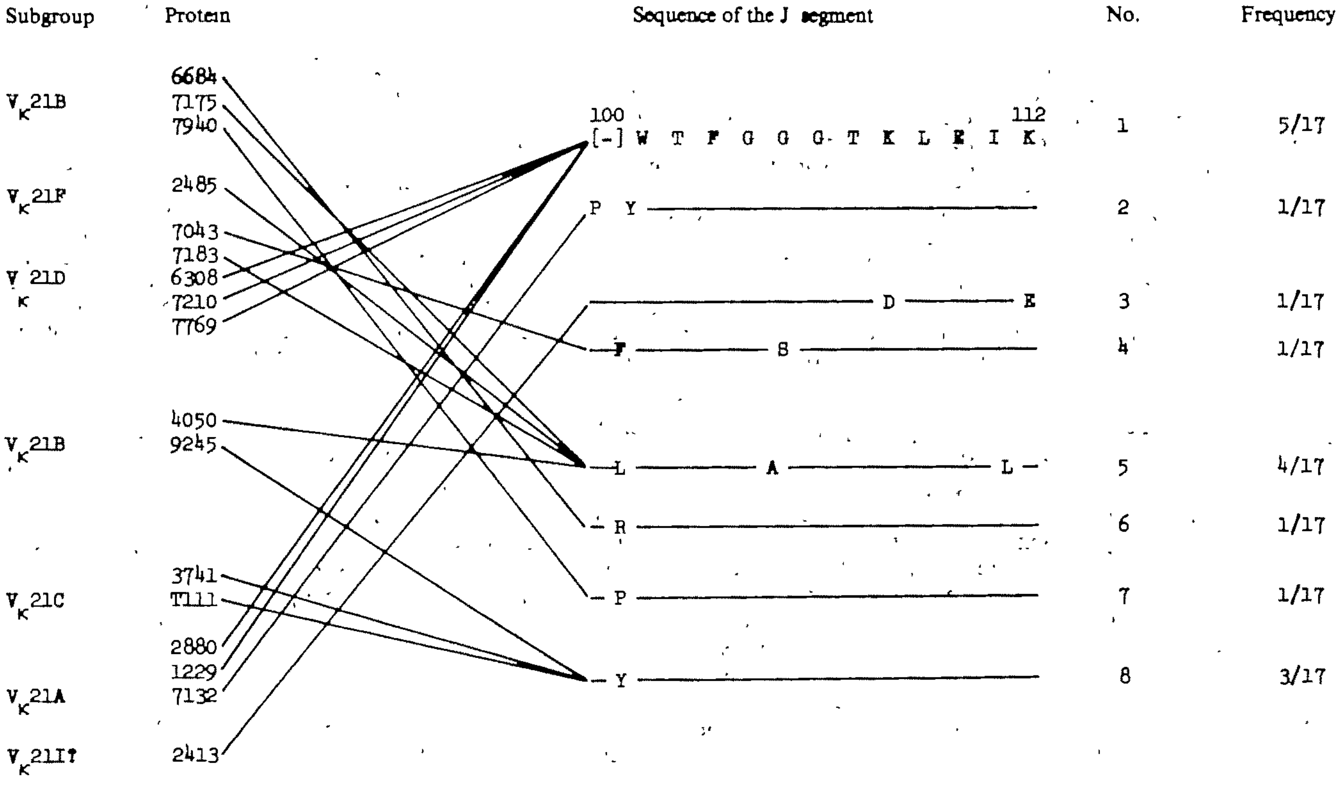
single J segment may be joined in a combinatorial fashion to each V segment to provide another stage in the amplification of antibody diversity. We describe this process as combinatorial joining. Indeed, position 101 is among the most variable in the $V_\kappa 21$ regions examined (Fig. 2). This diversity might include sequence gaps (insertions or deletions) as well as nucleotide substitutions. The sequence gaps would result from J regions of different length (for example, proline at position 100 in PC7132).

The precise size of the J segment of $V_\kappa 21$ genes must wait the DNA sequence analysis of $V_\kappa 21$ genes from differentiated and undifferentiated DNA. If J does not include part of the third hypervariable region, then combinatorial joining, as such, would not generate diversity in the combining site. In this case, invariant associations such as the leucine at 101 with alanine at 105 and leucine at 111 as well as the pattern of substitutions at position 101 require an alternative explanation.

The J segment may also mediate the joining of V, J and C gene information. DNA rearrangements and mRNA splicing[36–38] must occur before the V, J and C gene information is joined into a single cytoplasmic mRNA (Fig. 5). The joining of V and J regions seems to occur at the DNA level[18]. The intervening

Fig. 4 A diagram illustrating the independent association of the V segments (residues 1–99) and the J segments (residues 100–112).



DNA sequence between the J and C regions could either lack other J regions (Fig. 5*a*) or contain them, in which case they would be eliminated by RNA processing (Fig. 5*b*).

Intra-subgroup variability

The analysis of the intra-subgroup diversity in mouse λ chains presented a simple mutational pattern consistent with somatic mutation[15]. Likewise, if each of the six $V_\kappa21$ subgroups is encoded by a single germline V gene, the nature and patterns of substitutions within each subgroup should reflect the mechanism of somatic mutation. The 12 intra-subgroup substitutions within the $V_\kappa21$ regions are indicated by circles in Fig. 2. Several features distinguish these V_κ substitutions from their V_λ counterparts discussed earlier. (1) Two of 12 substitutions are found outside the hypervariable regions. (2) Four of six variant sequences have two or more substitutions. If these differences arise by somatic mutation, the mutational mechanism operates outside as well as within hypervariable segments and shows a tendency to generate multiple substitutions in individual variant sequences. Moreover, somatic mutation followed presumably by antigen selection seems to favour diversity at certain sites in the hypervariable regions.

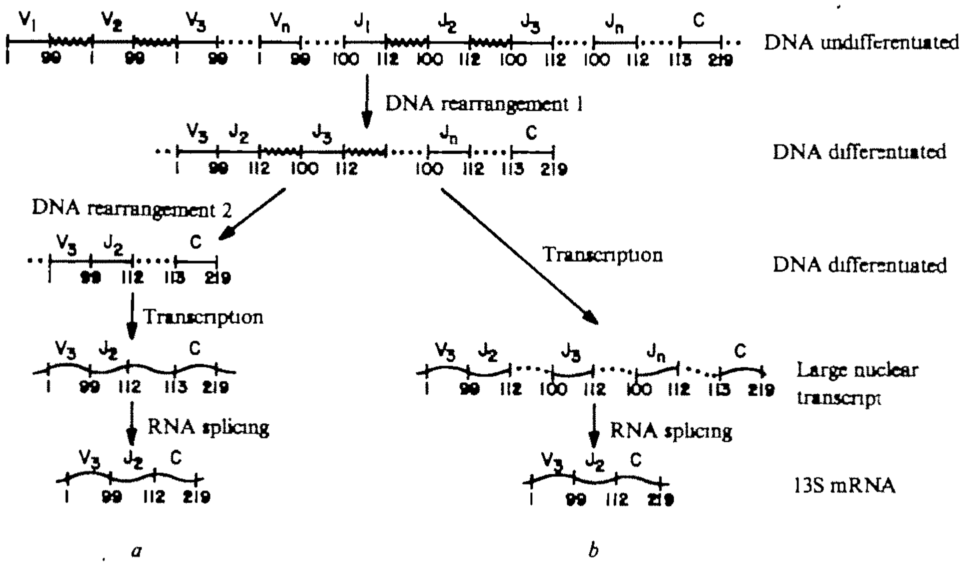


Fig. 5 Hypothetical models for the DNA segments of mouse κ genes. These gene segments are rearranged at the DNA level, presumably as the lymphocyte differentiates. As with λ genes, DNA rearrangement is depicted as joining the V and J segments[4] There are at least two pathways for joining the J and C segments at the nucleotide level. *a*, A second DNA rearrangement moves the J_2 segment closer to the C segment, possibly deleting the intervening J sequences. A recent report suggests that two or more DNA rearrangement events can occur in lymphocytes during the switch in synthesis from one to a different immunoglobulin class[48]. Final joining occurs by mRNA splicing. *b*, A large nuclear RNA transcript complete with the intervening J segments is processed by mRNA splicing enzymes

Again, this analysis of intra-subgroup variability must be qualified by the possibility that one variant differing by two or more residues from the prototype sequence will become a distinct subgroup when a second identical sequence is determined. Thus, perhaps the reason the intra-subgroup variability in the $V_\kappa21$ chains and the λ chains differ is that in the former some of the variants are encoded by additional germline V genes.

Sources of antibody diversity

The analysis of the V_κ 21 group of mouse V_κ regions offers certain insights into each of four basic mechanisms for producing antibody diversity.

Multiple germline V genes: According to a statistical analysis of N-terminal data, there are about 50 κ groups[15,39]. This number may be an underestimate because it is based on the sequences of myeloma proteins which may represent only a subset of the total V genes. Our studies suggest the $V_\kappa21$ group is encoded by at least six V genes. In addition, studies at the DNA level on three V_κ groups suggest that four to eight germline V genes are present in each group[23,32]. If we assume that seven germline V genes are present in each group defined by N-terminal analysis, then approximately 350 germline genes encode the V_κ family. Less is known about the diversity in the V_H gene family, but a similar estimate of at least 200 V_H genes seems reasonable.[39] In contrast, the mouse λ gene family is apparently encoded by one or two germline genes.

Combinatorial association: That most light chains may combine with most heavy chains is suggested by several types of observations[19,40,41]. This non-genetic mechanism for generating antibody diversity is termed combinatorial association. In principle, 350 V_L and 200 V_H regions could, through combinatorial association, generate 7×10^4 different types of antibody molecules. If the mammalian antibody repertoire is greater than 10^6 (see ref. 42), and if we assume that there are only 350 V_L and 200 V_H germline genes, then more than 90% of the antibody repertoire must be generated by somatic mechanisms.

Somatic mutation: All the intra-subgroup substitutions noted in the $V_\kappa21$ regions are single-base substitutions, predominantly in the hypervariable regions. Obviously, some or all of this variation could arise by spontaneous somatic mutation or by a hypermutational mechanism.

Combinatorial joining: One potential source of somatic diversification is the combinatorial joining of multiple J segments and V segments (Fig. 5). Thirteen different J segments have already been identified in mouse κ chains. For example, if 10 different J segments may be joined to any of 350 different V segments, then 3,500 different V regions may be generated. If combinatorial joining of a similar magnitude occurs in light and heavy variable regions, 7×10^6 antibody molecules could be generated by this process.

Combinatorial joining could generate identical variants among mice of the same inbred strain In contrast, most somatic theories have assumed that the generation of diversity is a random process occurring by mutation, recombination or gene conversion. A reproducible somatic process could explain the patterns of diversity seen in certain immune responses. For example, the responses to α1,3-glucosyl linkages of BALB/c mice[43] and to the 4-hydroxy-3-nitrophenylacetyl hapten (NP) of C57BL/6 mice[44] are heterogeneous by isoelectric focusing, but the heterogeneity is limited to V_H and is reproducible in each case[45,46]. Perhaps this reproducible heterogeneity arises from the combinatorial joining of V_H–DEX or V_H–NP^b genes with a variety of different J_H segments. A similar possibility could explain the closely related heavy-chain sequences produced in response to the immunisation of guinea pigs against several haptens[47].

Other investigators have proposed combinatorial joining as a mechanism for antibody variability[7,8], but their models arose from the conviction that certain hypervariable regions may be associated with many different framework regions. For example, based on a computer analysis of all available V-region sequences, Kabat *et al.* have suggested the mini-gene model, which proposes that each of the three hypervariable regions and the four intervening framework regions are encoded by minigenes which are joined during differentiation[9]. The correlation of specific hypervariable and framework segments within certain V_κ21 subgroups (Fig. 2) argue against this general model. Our data suggest that Kabat's model is correct in principle, but that the combinatorial process occurs only within the third hypervariable region. The identification of a J segment in λ chains raises the possibility that combinatorial joining of V and J segments will be used by all three antibody families, λ, κ and H.

Conclusion

Antibody variability may be generated by a variety of mechanisms, some genetic (multiple V genes, combinatorial joining and somatic mutation) and others non-genetic (combinatorial association). Combinatorial joining is both a somatic and a germline mechanism in that it presumably rearranges germline information during somatic differentiation. The critical question that remains for the future is what are the relative contributions of these four basic mechanisms for generating diversity to the functional repertoire of antibody molecules? The answer to this intriguing question will obviously require combined chemical, biological and genetical approaches.

This research was supported by a grant from the NSF grants from the NIH and an appropriation from the Commonwealth of Pennsylvania. We thank Drs Michael Potter and David McKean who developed the serological methods essential for identifying V_κ21 light chains.

The arrangement and rearrangement of antibody genes

J. G. Seidman & Philip Leder

Laboratory of Molecular Genetics, National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, Maryland 20014

Cloned segments of mouse chromosomal DNA provide direct evidence for the somatic rearrangement of κ variable and constant region genes in antibody producing cells. This rearrangement apparently affects only one member of an allelic pair of light chain genes.

THE notion that immunoglobulin genes are encoded in several segments that rearrange during somatic differentiation has been incorporated into most theories of antibody diversity since the 'two gene–one polypeptide' argument was first advanced by Dryer and Bennet in 1965 (ref. 1). Most recently, certain details of this arrangement have become clear through a series of experiments involving the analysis of fragments containing chromosomal DNA encoding variable and constant region immunoglubulin genes. As predicted, constant and variable regions are separately encoded in germline DNA[2–4] and appear to be brought together by a somatic recombination event[5–7]. Moreover, it seems likely that this recombination is closely and critically related to light chain production; that is, that the rearranged variable region sequence will be the one expressed in a given immunocyte.

Further analysis of these genes, several of which have been cloned, indicates that their organisation is even more complex than originally suspected. The inactive κ and λ mouse variable region genes sequenced thus far fail to encode the last 10 or so amino acids that had, by sequence analysis, always been associated with the variable region[4,8]. In a direct examination of a

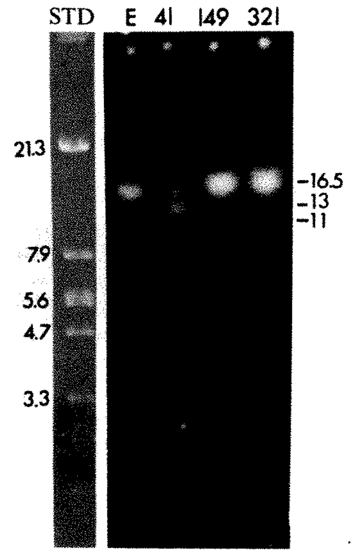

Fig. 1 Analysis of the *Bam*H1 fragments of BALB/c embryonic and plasmacytoma DNAs annealed to a constant region gene sequence. The fragments obtaind by BamH1 digestion of embryonic (E), MOPC-41 (41), MOPC-149 (149) and MOPC-321 (321) DNA were fractionated by electrophoresis (from top to bottom) in a 0.7% agarose gel, denatured, neutralised, transferred to nitrocellulose sheets and hybridised with a ^{32}P-labelled DNA fragment (136 c.p.m. per pg) which contained constant region sequences as described previously[4]. The constant region containing DNA fragment used as probe was the 2.8-kilobase *Bam*H1–*Hin*dIII fragment indicated in Fig. 6, which contains the κ constant region gene. The embryo specific band (16.5 kilobase) and the plasmacytoma specific bands (13.0 and 11.0 kilobases) are indicated. Fragment lengths were determined by comparison with ethidium bromide-stained, *Eco*R1 fragments of phage λ DNA of indicated length (STD).

cloned embryonic mouse λ light chain DNA fragment, Tonegawa and his associates have shown that this terminal variable region segment, called the J sequence, is separately encoded[9]. While the precise borders of these regions have not yet been determined, it seems that some—if not all—light chain genes are encoded in at least three segments, a major variable region sequence, a short J sequence and the constant region sequence. This observation also seems to fit in with recent comparisons of amino acid sequence data (ref. 10 and M. G. Weigert and L. Hood, personal communication).

Since the somatic rearrangement of these three segments may play a part in generating antibody diversity as well as in antibody gene activation, it will be important to determine whether gene rearrangement is a constant feature of immunocyte development and to understand its precise molecular basis. In some respects this is most advantageously investigated in the mouse κ light chain system where hundreds of variable region genes exist in the embryonic chromosome[4,11] and are presumably candidates for rearrangement and, hence, expression.

In what follows we describe the cloning and characteristics of several immunoglobulin κ light chain genes derived from the chromosomes of embryonic and κ chain producing cells. While different gene arrangements appear in each producing myeloma cell line, the basic embryonic gene arrangement is also preserved in each. One of the rearranged fragments contains an entire light chain sequence in which variable and J sequences appear contiguous and are separated from the constant region gene by a 3.7-kilobase intervening sequence of DNA. Several cloned κ gene fragments have also recently been obtained by Lennard-Schuller *et al.*[21].

Cloning fragments containing constant region genes

By using hybridisation probes derived from cloned κ light chain cDNA, we were previously able to identify several *Eco*R1 fragments of embryonic and myeloma DNA (MOPC-149 and MOPC-41) that encoded closely related variable region gene sequences[11]. In contrast, each tissue yielded what appeared to be a single *Eco*R1 fragment of DNA encoding a constant region sequence that curiously migrated at approximately the same position in a two-dimensional analysis involving RPC-5 chromatography and gel electrophoresis[11]. Evidently, whatever rearrangement occurred amongst these genes, it resulted in the production of new DNA sequences that closely resembled the embryonic *Eco*R1 pattern in length and chromatographic properties.

That the gene rearrangement had actually occurred in MOPC-149 and MOPC-41 cells could be demonstrated using a different restriction enzyme to produce a new fragment pattern in the producing cells. DNA from embryonic, MOPC-41, MOPC-149 and MOPC-321 cells were digested with *Bam*H1, electrophoresed, blotted to nitrocellulose sheets[12] and annealed to a radioactive probe corresponding to the κ constant region (Fig. 1). Each tissue, including embryo, yielded a 16.5-kilobase DNA fragment that contained constant region sequences. Each myeloma, on the other hand, yielded an additional fragment, in the case of MOPC-41, approximately 13 kilobases long, in the case of MOPC-149 and MOPC-321, 11 kilobases long. (MOPC-321 was previously analysed with *Bam*H1 by Hozumi and Tonegawa[5] and was included as a control. The constant fragments we observe differ in size from those seen by the earlier workers and retain the germline fragment which was apparently not observed in their analysis. It is possible that we are dealing with different tumours.) Given these results, it seemed likely

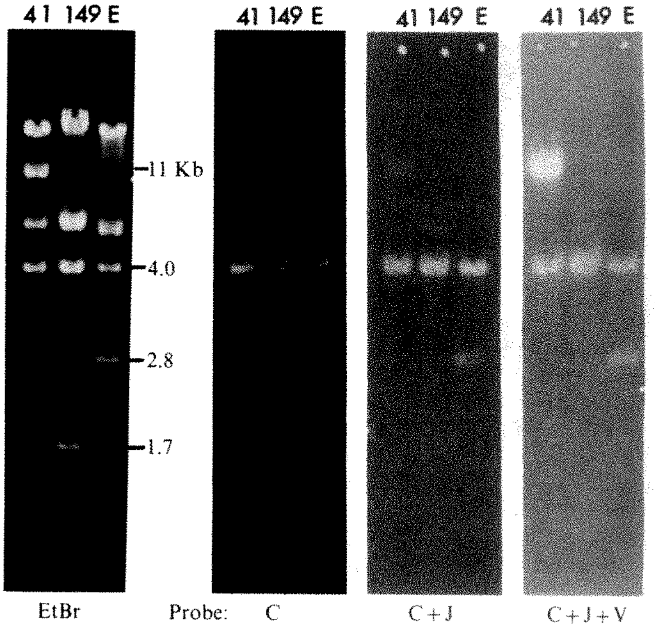

Fig. 2 Restriction endonuclease *Hin*dIII digestion of cloned embryonic and plasmacytoma DNA fragments encoding κ gene sequences. The fragments obtained by *Hin*dIII digestion of λCh4A phage containing 41KC-21, 149C-2 and EC-5 *Eco*R1 DNA fragments were fractionated on a 1.2% agarose gel and stained with ethidium bromide (EtBr). The *Hin*dIII fragments (left) were denatured, transferred to nitrocellulose sheets and hybridised separately to three ^{32}P-labelled probes and autoradiographed (right) as described previously[4,11]. The probes were ^{32}P-labelled fragments containing segments of the κ light chain. The constant region probe was a *Hpa*I/*Bam*H1 fragment obtained from pBR322-K41 (ref. 11) which should encode from amino acids 125 through the 3' untranslated end. The J region (J+C) probe was a *Hin*cII fragment obtained from pCR1-K149 (ref. 19) which encodes amino acids 90–125 of the MOPC-149 light chain. The variable region probe ($V+J+C$) was a *Bam*H1/*Hin*cII fragment cleaved out of pBR322-K41 (ref. 11) which encodes amino acids 44–125 of the MOPC-41 light chain. The sizes in kilobases of the *Hin*dII fragments were determined relative to phage λ *Eco*R1 fragments. 149KC-2 does not have a separate fragment that hybridises to the J region probe, while 41KC-21 has both a J region and a variable region gene sequence.

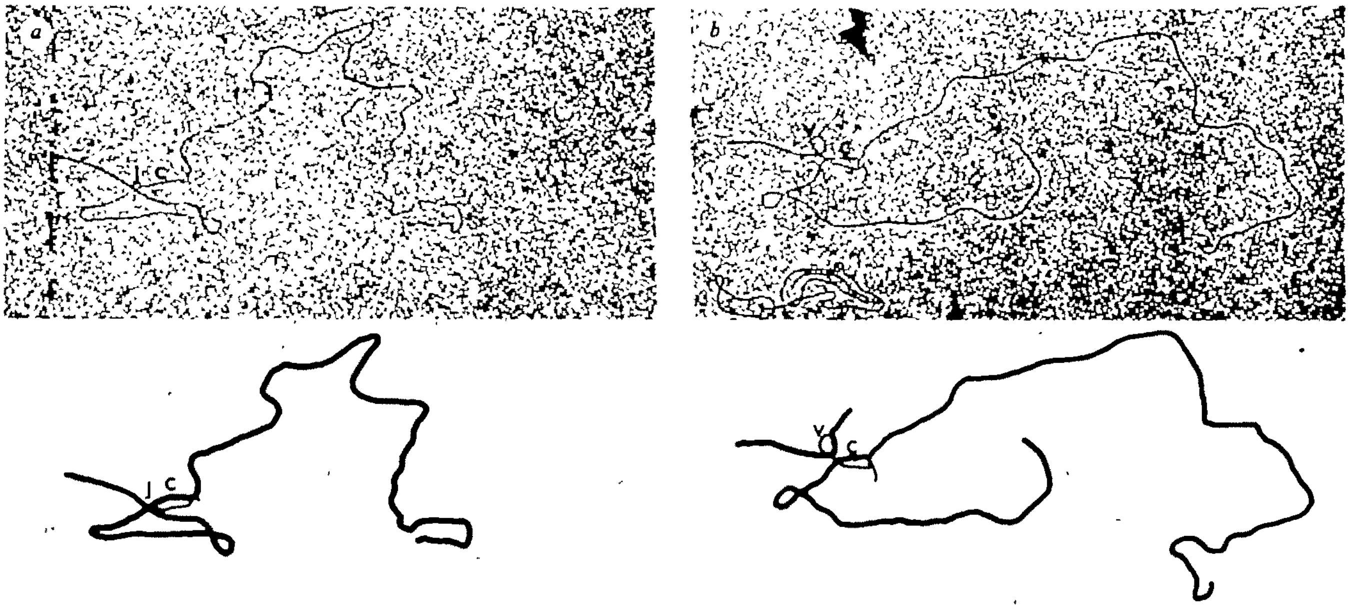

Fig. 3 Visualisation of the κ light chain sequences encoded by two cloned *Eco*R1 fragments derived from embryonic DNA and MOPC-149 DNA. *a*, The 16.0-kilobase *Eco*R1 fragment isolated from the phage λCh4A-EC-5 was annealed to MOPC-41 mRNA and spread for electron microscopic analysis as described previously[21]. *b*, The 14.9-kilobase *Eco*R1 fragment (20 μg ml^{-1}) from the phage λCh4A-149C-2 and an 1800-base pair *Hae*III fragment (20 μg ml^{-1}), from pMB9-K2 which encodes a MOPC-149-like variable region[4] were annealed with a MOPC-149 mRNA (10 μg ml^{-1}) in 70% formamide, 0.5 M NaCl, 0.1 M Tricine *p*H 8.0, 0.01 M EDTA at 52°C for 18 h, and spread for electron microscopy. The R loops are interpreted by diagrams drawn immediately below each molecule. The constant region R loop (C), 475 ± 78 base pairs long and the variable region R loop (V) is 299 ± 68 base pairs long. The analysis of 35 molecules suggested that the constant region R-loop is 10.4 ± 0.24 kilobases, from one end and 5.1 ± 0.20 kilobases from the other end of the fragment. The location of the *J* region gene was determined by the distance, 1.3 ± 0.19 kilobases, from the end of the fragment to the point where the DNA falls across the end of the R loop. The long ends of both DNA fragments are single stranded because of nicks introduced into the DNA by nuclease in the *Eco*R1 preparation Although some of the *Eco*R1 fragments had single stranded ends nearly all of the fragments were full length when the single strand DNA was included in the length of the fragment.

that the *Eco*R1 digestion of the DNA from each tumour produced a mixture of germline and rearranged fragments of approximately the same size. Obviously their structural features could best be resolved by cloning.

The *Eco*R1 fragments from embryonic and plasmacytoma DNA which contained constant region gene sequences were therefore cloned, using procedures previously used to clone the mouse globin[13–15] and κ variable region genes[4]. *Eco*R1 fragments containing κ constant region sequences were purified first by RPC-5 column chromatography and then by preparative gel electrophoresis, ligated to the DNA of the EK2 vector λCh4A (ref. 16) and finally packaged into phage particles using the procedure developed by Becker and Gould[17] and Sternberg, Tiemeier and Enquist[18] as modified by F. Blattner and his co-workers (personal communication). In this way, 8×10^4 hybrid phage were derived carrying embryonic DNA fragments. Of these, 20 contained constant region sequences. Twenty thousand hybrid phage were derived carrying MOPC-149 DNA fragments. Four contained constant region sequences. Ten thousand hybrid phage were derived carrying MOPC-41 DNA fragments. Three contained constant region sequences.

Light chain producing cells contain both embryonic and rearranged constant region genes: restriction enzyme mapping

Antibody production seems to involve the expression of only a single allele of the pair of genes presumably present in diploid cells. While various potential mechanisms might be invoked to account for this allelic exclusion, it is appealing to consider that the rearrangement of only one member of an allelic pair might create only one complete and functional copy of light and heavy chain genes. We have already noted that the constant region *Bam*H1 restriction fragment pattern derived from the plasmacytoma cells reveals one fragment that is the same size as that seen in embryonic DNA (Fig. 1) If only one of the constant region alleles has undergone rearrangement, we might expect to find, in addition to the rearranged fragment, several fragments among our plasmacytoma-derived clones that are identical to those cloned from embryonic DNA, that is, non-rearranged fragments. To test this possibility, the DNA from five of the embryo-derived constant region gene containing phage and DNA from each of the phage carrying MOPC-41 and MOPC-149 constant region sequences were cleaved with several restriction enzymes and the resulting fragments were fractionated on agarose gels (data not shown). Not surprisingly, all five phage DNAs isolated from embryonic DNA were apparently identical (except with respect to their orientation within the vector). Furthermore, three of the four MOPC-149 derived phage and two of the three MOPC-41 derived phage seemed to be identical to the phage derived from embryonic DNA. It is possible that some of these embryo-like fragments were derived from non-plasmacytoma cells present in tumour tissue. This seems less likely in view of the minor degree of tissue contamination observed microscopically and the prevalence of embryo-like fragments among hybrid clones.

Although several of the cloned fragments obtained from plasmacytoma DNA were apparently identical to that derived from embryonic DNA, one cloned fragment from each light chain producing cell differed from the embryonic DNA fragment. These two isolates, derived from plasmacytoma MOPC-149 and MOPC-41 DNAs, were designated 149KC-2 and 41KC-21, respectively. (The phage isolate containing the embryo-derived *Eco*R1 fragment which was used for comparison in these studies was called EC-5.) When the phage DNAs were cleaved with *Eco*R1 and fractionated on a 0.6% agarose gel, small differences in the sizes of the three constant region containing fragments could be detected; the fragments EC-5, 149KC-2 and 41KC-21 were 16.0, 14.9 and 16.5 kilobases respectively (data not shown). While these differences became more obvious when the hybrid phage were cleaved with the restriction endonuclease *Hin*dIII (Fig. 2), the differences between the fragments were not great, suggesting that there was substantial homology between them. Indeed, most enzyme digests produced several fragments that were identical in length among the three phage and yielded only one or two fragments that actually differed.

To determine which of the restriction fragments contain portions of the light chain structural gene, the separated fragments were denatured in the gel, transferred to nitrocellulose sheets and hybridised to the appropriate ^{32}P-labelled probes corresponding to different segments of the κ light chain mRNA. An example of results obtained in this way is shown in Fig. 2. A single 4.0-kilobase *Hin*dIII fragment anneals to a cloned constant region cDNA probe (extending from codon position 125 through the 3′ untranslated sequence) and is found in all three genomic fragments. Surprisingly, a probe incorporating the variable–constant region junction (codon 90–125), presumably including the suspected J sequence, hybridised to two fragments in the digest of the embryonic clone, indicating that this sequence is interrupted by *Hin*dIII site in the embryonic genome. The second fragment is absent from MOPC-149 clone, but is present on the clone derived from MOPC-41 DNA (Fig. 2). Apparently, this particular J region gene sequence has been lost in the chromosomal rearrangement that produced the new MOPC-149 fragment.

Since two of these cloned *Eco*R1 fragments (from embryo and MOPC-41 DNA) contained both a J region gene and a constant region gene, either might also carry a variable region gene. The fragment derived from MOPC-149 DNA, while rearranged, failed to hybridise to MOPC-149 variable region coding sequence (data not shown). Therefore, as we had already concluded from previous analyses of genomic DNA[4], an *Eco*R1 site separates variable and constant region genes in the MOPC-149 genome. On the other hand, the MOPC-41 V + J + C region gene probe hybridises much more strongly the 11.0-kilobase *Hin*dIII fragment derived from the MOPC-41 hybrid phage than did the probe containing only the J and constant region sequences. This suggests that the new MOPC-41 *Eco*R1 fragment might contain the variable region as well as the J and the constant region sequences (see below). That is, the entire MOPC-41 light chain structural gene might be encoded in this single *Eco*R1 fragment.

Visualisation of embryonic and rearranged MOPC-149 gene sequences

In situ hybridisation analysis indicated that the three *Eco*R1 constant region fragments contained extensive regions of homology, but were nevertheless different from one another. The embryonic clone—which was repeatedly discovered among cloned fragments derived from each plasmacytoma—encoded a constant region sequence and a J sequence homologous to that represented in MOPC-41 cDNA. The rearranged DNA segment derived from MOPC-149 DNA encoded a constant region sequence, but had evidently lost the nearby J region segment and, as a new *Eco*R1 site interceded between constant and variable region, a MOPC-149 variable region sequence did not occur on our cloned fragment. The rearranged DNA segment derived from the MOPC-41 DNA, on the other hand, seemed to encode all three segments. (These features are summarised in the map of each fragment represented in Fig. 6.)

The presence of each of these structural features could be confirmed and their relative position on each fragment determined by direct visualisation of R-loop structures formed by annealing light chain (MOPC-149 or MOPC-41) mRNA to each segment. In appropriate conditions, the light chain mRNA anneals to complementary sequences in one of the DNA strands forming a double-stranded RNA–DNA hybrid and displacing the other strand to form a bubble-like structure called an R loop[20]. When the embryonic fragment (EC-5) was examined in this way, a single R loop 475 ± 78 base pairs long was observed, located 5.1 ± 0.20 and 10.4 ± 0.24 kilobases from the ends of the fragment (Fig. 3*a*). A similar structure was observed when the fragment derived from MOPC-149 was analysed (Fig. 3*b*). In both cases, the loop structure should represent the constant region sequence (Fig. 2). This could be confirmed and the gene orientated (5′ – 3′) by forming a second R loop using a previously cloned DNA fragment known to encode a MOPC-149-like variable region gene[4] (Fig. 3*b*). Here the light chain mRNA links the two cloned fragments by forming an R loop on the smaller variable region fragment (1.8-kilobase *Hae*III fragment of pMB9-K2)[4] and the larger constant region fragment. The smaller fragment serves as a marker to identify the 5′ side of the constant region R loop and confirms that the constant region sequence is annealed to the larger, MOPC-149 fragment. Similar structures were visualised using the embryonic fragment.

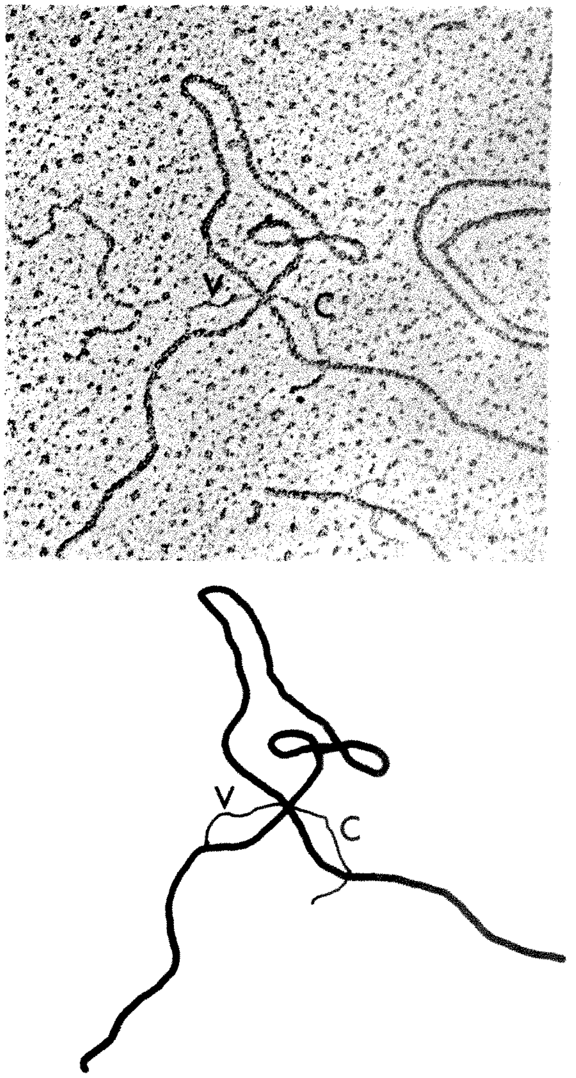

Fig. 4 The R loop formed between a fragment cloned from MOPC-41 DNA and MOPC-41 mRNA. The variable (V) and constant (C) region R loops formed as described previously[4] are separated by 3.7 ± 0.187 kilobases of DNA. Twenty-five molecules were measured.

The J region sequence on the embryonic fragment could also be identified by electron microscopic visualisation, despite its small size. The J region is too small to form a visible R loop, but could form a stable hybrid when annealed to MOPC-149 mRNA (Fig. 3*a*). Our hybridisation studies already suggested that this sequence was not immediately adjacent to the constant region sequence (Fig. 2). Indeed, if the J region were encoded at a distance from the constant region gene, we would expect to find molecules containing a constant region R loop and an intervening loop of double-stranded DNA joined to the constant region R loop by the J sequence in the mRNA. We identified 10 such structures in which a ~3.7-kilobase length of

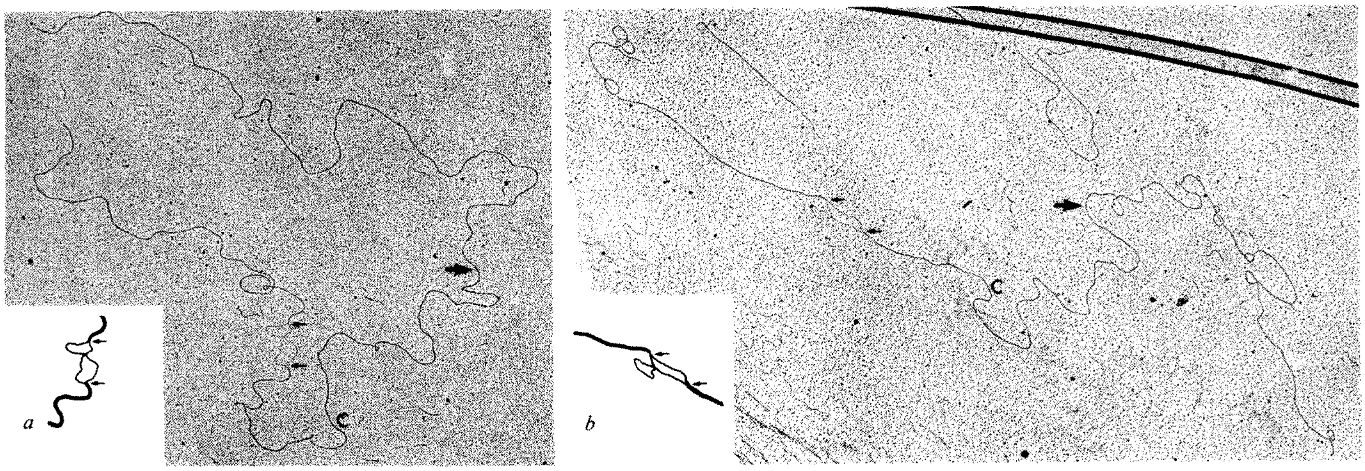

Fig. 5 Heteroduplexes formed between DNAs carrying embryonic and plasmacytoma constant region gene sequences. *a*, A heteroduplex formed between λCh4A-EC-5 (embryonic) and λCh4A-41C-21 (plasmacytoma) DNA. *b*, A heteroduplex formed between Ch4A-EC-5 and Ch4A-149C-2 (plasmacytoma) DNA. The techniques for forming the heteroduplexes and spreading them for electron microscopy were as before[14]. The large arrow indicates the approximate location of the *Eco*R1 site in the phage DNA which is about 10.4 kilobases from the constant region gene (indicated by 'C'). The smaller arrows indicate the ends of single stranded regions which indicate non-homology between the two DNAs. The non-homology seen in these heteroduplexes is due to a DNA sequence present in plasmacytoma DNA, presumably introduced by a recombination event that occurred during the differentiation of the MOPC-149 and MOPC-41 cell lines. The measured lengths of single-stranded DNA in these heteroduplexes was used to determine the exact location of the recombination event with respect to ends of the *Eco*R1 fragments. Twenty-five molecules were measured.

DNA recrossed itself adjacent to the 5′ end of the constant region R loop as shown by the molecule in Fig. 3*a*. That this structure is merely the result of the DNA twisting back over itself seems unlikely for three reasons. First, we never saw the DNA from the 10.4-kilobase side of the fragment twist over the end of the R loop. Second, in the 10 molecules observed, the J sequence was always 1.3±0.19 kilobases from the end of the fragment. Third, we could not find this hairpin structure when we formed an R loop between MOPC-149 mRNA and the MOPC-149 DNA fragment and we knew from *in situ* hybridisation studies (Fig. 2) that this fragment does not have a J region sequence (Fig. 2). Thus, we conclude that the embryonic *Eco*R1 fragment contains a J region gene about 3.7 kilobases from the constant region gene. These features are summarised diagrammatically in Fig. 6.

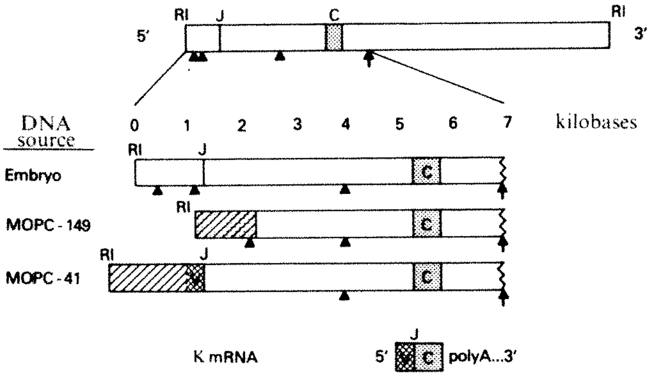

Fig. 6 Arrangement of light chain gene sequences on the *Eco*R1 fragments cloned from embryonic and plasmacytoma DNA. The *Eco*R1 fragment from embryo (16.0 kilobase) DNA is shown with the 5′ end of the constant region gene to the left. The portions of the cloned fragments which differed from one another are shown on an expanded scale. The positions of the *Eco*R1, *Bam*H1 and *Hin*dIII restriction sites in this region are indicated. The segments of the light chain, the variable region (V), the J sequence (J) and the constant region (C) are indicated. The hatched segments in the plasmacytoma fragments, MOPC-149 and MOPC-41, represent DNA segments that are not present in the embryonic fragment. Note that they are different from each other as well. The κ light chain mRNA is diagrammed to indicate the size of the structural gene relative to the size of the intervening sequence in the MOPC-41 light chain gene.

The rearranged MOPC-41 fragment encodes a complete light chain gene and is interrupted by a 3.7-kilobase intervening sequence

In contrast to the embryonic and MOPC-149 segments, the 16.5-kilobase *Eco*R1 fragment cloned from MOPC-41 DNA hybridised to all three segments of the light chain sequence (Fig. 2). The R loop structure formed by annealing this fragment to MOPC-41 mRNA reflects this difference (Fig. 4). Instead of a single R loop, two are formed. Both flank a large, 3.7-kilobase intervening sequence that interrupts the structural gene and is not represented in the mature light chain mRNA. A tail, probably representing poly A, is frequently seen on the constant region end of the structure and its associated R loop measures 409±128 base pairs. The variable region R loop measures 229±68 base pairs. The sequence is also represented diagrammatically in Fig. 6.

Recombination sites defined on the two plasmacytoma-derived *Eco*R1 fragments

We have shown by restriction mapping and R loop analyses that the two plasmacytoma-derived fragments are related to, but different from each other and the fragment derived from embryonic DNA. In order to define more closely the relationship between these three constant region encoding fragments and to compare their sequences, we have formed heteroduplexes between these fragments cloned in the λCH4A vector. An example of the heteroduplex structures formed between the phage containing the embryonic fragment and the phage containing the MOPC-41 segment is shown in Fig. 5*a*. The genomic fragments (whose ends are defined by the arrows closest to the ends of the double-stranded DNA in Fig. 5*a*) form a homologous, double-stranded structure for about 14.8 kilobases and then diverge at one end (the single-stranded bubble). Since the right arm of the λCh4A vector DNA is shorter than the left[16], the orientation of the fragment and the location of the differences between the two fragments are defined at the points of divergence in the heteroduplex molecules. Thus, the rearranged MOPC-41 fragment differs from embryonic fragments by a segment of DNA introduced at its 5′ end at approximately the position of the embryonic J sequence (Fig. 6).

Similarly, the point of divergence in the rearranged MOPC-149 fragment could be determined. A heteroduplex formed between the phages containing the embryonic fragment and the

MOPC-149 fragment is shown in Fig. 5*b*. The fragments are homologous for 13.5 kilobases, but also diverge at their 5′ end. In each case, the divergent heteroduplex bubble represents DNA that is different in the embryonic sequence. Evidently these new sequences are derived from a recombination-like event which joined DNA sequences to the 5′ ends of plasmacytoma DNA fragments and eliminated sequences present in the embryonic fragment (see diagram, Fig. 6). By measuring the lengths of the single-stranded DNAs found in each heteroduplex, we can estimate the lengths of the new DNA sequences that have been joined to the embryonic *Eco*R1 fragment. The points at which the embryonic fragment differs from each rearranged fragment defines the site at which the recombination event took place.

The recombination events that formed the new MOPC-149 and MOPC-41 fragments involved different sites. In MOPC-149 the recombination event appears to have occurred 2.7 kilobases from the constant region gene and removed the MOPC-41-like J region sequence from the embryonic fragment. Presumably the MOPC-149 light chain uses a different J region sequence. The recombination event that generated the MOPC-41 light chain sequence occurred 3.7 kilobases from the constant region gene, very close to the J region sequence found in the embryonic fragment. Here a single recombination event may have linked the MOPC-41 variable region to the MOPC-41 J region to generate the cloned fragment. However, until the nucleotide seuences of the appropriate regions have been determined, we cannot be certain that the recombination event that generated the MOPC-41 gene did not actually replace the embryonic J region with a MOPC-41 J region at the same relative position. It is also possible that both J region sequences are present on the MOPC-41-derived fragment. Nevertheless, these analyses indicate that the recombination events that affect immunoglobulin light chain genes can involve sites at least 1.0 kilobases apart.

The emerging picture of antibody gene arrangement and rearrangement

By characterising cloned, κ chain-encoding segments of DNA derived from mouse embryo and antibody producing cells, we demonstrate directly that immunoglobulin constant and variable region genes undergo a somatic rearrangement that brings together the segments necessary to encode a complete κ light chain gene. Moreover, in each light chain producing plasmacytoma that we have thus far examined there is evidence of somatic rearrangement of one set of these genes, while a second, presumably allelic, set retains the original embryonic pattern. These observations fit well with the plausible notion that rearrangement of a single allele is instrumental in immunoglobulin gene activation and that it may play a part in allelic exclusion in antibody production.

In addition we see that, like the mouse λ light chain[9], κ genes are encoded in at least three segments in embryonic DNA, a foreshortened variable region sequence[4], a short J sequence probably encoding the last 10 or so amino acids of the variable region and, finally, the constant region sequence. Rearrangement of these sequences (which may itself contribute to the generation of antibody diversity) forms, in the case of the MOPC-41 light chain gene, a new chromosomal sequence in which variable and J sequences are adjacent, but separated from the constant region gene by a large 3.7-kilobase intervening sequence of DNA. In the case of MOPC-149, this rearrangement has eliminated the embryonic J sequence and replaced it, in our clone, with a new segment of DNA. Whether this new segment is a portion of the intervening sequence linking MOPC-149 variable and constant regions in genomic DNA is not known. In contrast to what might have been expected, these rearrangements do not occur at a single site, but the new DNA segments are joined at sites about 1.0 kilobases apart on the 5′ side of the constant region gene. The precise nature and the molecular basis of this recombination remains unclear. Further studies should indicate whether or not reciprocal recombination is involved and whether this recombination is mediated by regions of sequence homology.

We thank Dr Fred Blattner for the λCH4A phage system, Barbara Norman, Marion Nau and Aya Leder for help in the gene purification and cloning experiments, Margery Sullivan for help with the electron microscopy and Dr Henry I. Miller for help with preparative gel electrophoresis. We thank Aya Leder for suggesting the gene orientation experiments shown in Fig. 3*b*, and Terri Broderick for assistance in preparation of this manuscript.

Synthesis of growth hormone by bacteria

P. H. Seeburg, J. Shine, J. A. Martial, R. D. Ivarie, J. A. Morris, A. Ullrich, J. D. Baxter & H. M. Goodman

Howard Hughes Medical Institute Laboratory, Department of Biochemistry and Biophysics, Department of Medicine, and Metabolic Research Unit, University of California, San Francisco, California 94143

A hybrid gene was constructed between the β-lactamase gene of plasmid pBR322 and the cloned coding sequence for rat growth hormone. This gene is expressed in bacteria and growth hormone sequences are detectable by immunological methods.

RECENT advances in recombinant DNA technology have led to the cloning in bacteria of the natural coding sequences for several mammalian peptide hormones[1–3]. These sequences provide excellent material for testing the feasibility of producing mammalian proteins in bacteria. The success of such production depends on the correct design and construction of new genes in which suitable bacterial control elements promote expression of

0028–0836/78/0276—0795$01 00

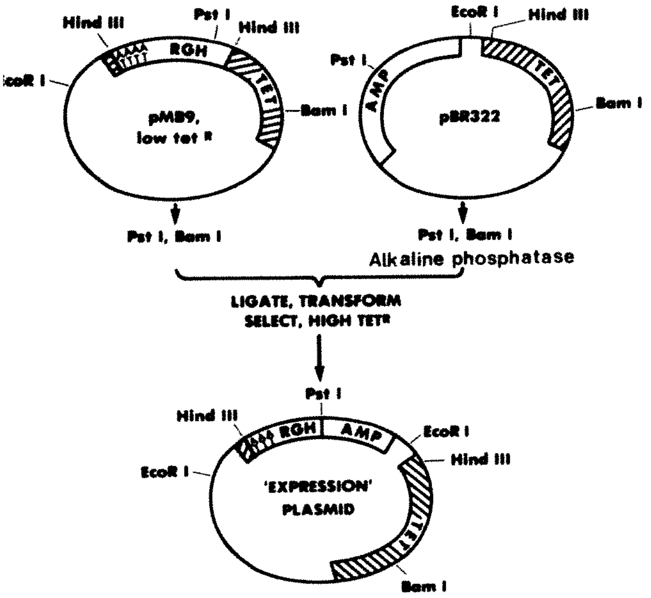

Fig. 1 Construction of a vector for bacterial synthesis of GH sequences. The cloned RGH cDNA was cleaved from plasmid pRGH-1 (ref. 2) with *Hin*dIII endonuclease and isolated by polyacrylamide gel electrophoresis. This DNA was enzymatically ligated to similarly cleaved and alkaline phosphatase-treated[1,3] pMB9. The ligation mixture was used to transform *E. coli* strain χ1776 (refs 1–3). Colonies containing plasmids were selected by growth on low levels (5 μg ml^{-1}) of tetracycline[11]. Resistant colonies were examined for the presence of plasmids containing inserted RGH sequences by gel analysis of such plasmids after digestion with restriction endonuclease *Pst*I and *Eco*RI. In some plasmids RGH DNA was found to have its poly dA · dT end orientated towards the single *Eco*RI site in pMB9. Such a plasmid (pMB9-RGH) was used in the subsequent steps for vector construction. The pre-RGH sequences from pMB9 were placed under the control of the β-lactamase gene of pBR322, as indicated. Plasmid pMB9-RGH was digested with *Pst*I plus *Bam*HI endonuclease. The single cleavage site for *Pst*I in this plasmid occurs between amino acids −24 and −23 of the pre-sequence of RGH (see Fig. 2), whereas the single *Bam*HI site is in the gene responsible for bacterial tetracycline resistance[9]. The amp^r and tet^r plasmid pBR322 was similarly digested with these two enzymes. In pBR322 the *Pst*I site occurs at a sequence coding for amino acids 182 and 183 of pre-β-lactamase[10]. The *Bam*HI site is in the *tet*^{r} gene and is in exactly the same place as in pMB9, as this region of pBR322 was derived from pMB9 (ref. 9). After digestion, pBR322 was treated with bacterial alkaline phosphatase[1,3]. This mixture was then ligated to the *Pst*I and *Bam*HI cleaved pMB9-RGH. After transformation of *E. coli*, colonies were selected for their ability to grow on high levels (20 μg ml^{-1}) of tetracycline.

the appropriate coding sequences. We describe here the construction of such a hybrid gene on a bacterial plasmid designed to program bacteria for the synthesis of pituitary growth hormone (GH) sequences. This peptide hormone is crucial for linear growth. A sufficient supply would allow wider therapeutic use in the treatment of growth disorders[4–6] and other conditions in man and might be useful in animal husbandry for more economical food production. The species specificity and size (190 amino acids) of GH[7,8] prevents us from exploiting existing resources or applying current synthetic techniques. Thus, for GH and similarly for a variety of other eukaryotic proteins, genetically programmed bacteria may provide an important resource.

Gene construction

Table 1 Radioimmunoassay of RGH in extracts from minicells containing pEx-RGH or pBR322

Plasmid	RGH by radioimmunoassay (ng ml^{-1})	
	Spheroplasts	Periplasmic space
pEx-RGH	89.1 (70.8–116.6)	30.8 (30.0, 31.6)
pBR322	Undetectable	Undetectable

One litre of *E. coli* P648-54 containing either pEx-RGH or pBR322 was grown to saturation and collected by centrifugation at 10,000*g* for 10 min. The cells were washed and spheroplasts were prepared by modification of procedures described elsewhere[15]. Briefly, cells were washed once in 200 ml of 10 mM Tris (*p*H 7.4) containing 1 mM PMSF (phenylmethylsulphonyl fluoride, Sigma). The cells were resuspended in 50 ml of 20% sucrose, 0.033 Tris (*p*H 8.0) and 1 mM PMSF. Ice-cold 0.1 M EDTA (*p*H 8.0) was added (0.5 ml) and the mixtures were kept on ice for 5 min. After addition of 1 ml of 5 mg ml^{-1} lysozyme (Sigma) the mixtures were incubated for 30 min at 0 °C and centrifuged (17,000*g*, 10 min, 0 °C). The supernatant media were saved for radioimmunoassay of material from the periplasmic space. The pellets were resuspended in 10 mM Tris (*p*H 8.0) and 1 mM PMSF. $MgCl_2$ was added to a final concentration of 10 mM with 200 μl each of DNase (1 mg ml^{-1}) and RNase (5 mg ml^{-1}). Incubation proceeded for 1 h at 4 °C (spheroplast sample). These mixtures (10 ml) and 50 ml of the samples containing periplasmic material were precipitated with $(NH_4)_2SO_4$ (50% saturation). The samples were resuspended in 4 ml of 50 mM Tris (*p*H 9.0), 0.1 M NaCl and 1 mM PMSF and dialysed against 2 l of the same buffer for 2 h at 4 °C. Serial dilutions of these samples were analysed by radioimmunoassay as described previously[19]. Amounts of RGH found by this assay are listed in ng ml^{-1} with the mean and range of these determinations for the spheroplast sample and the mean and individual values for duplicate samples from the periplasmic space sample. No activity was detected in samples from pBR322. The sensitivity minimum of the assay as assessed from the standard curve with authentic GH was 10 ng ml^{-1}. The high immune reactivity in the periplasmic space is probably due to lysis of some cells during spheroplast formation.

The construction of a hybrid gene between bacterial and mammalian DNA sequences, capable of directing synthesis of rat growth hormone (RGH) sequences in bacteria, is shown in Fig. 1. The bacterial sequences for this gene were excised from the multicopy plasmid pBR322 (ref. 9). They contain a portion of the gene (*amp*^{r}) coding for the enzyme β-lactamase which is secreted into the periplasmic space and is responsible for bacterial resistance to the antibiotic ampicillin[9]. The mammalian sequences were provided by cloned complementary DNA containing the entire coding region for the precursor form of rat pituitary GH[2]. Functional fusion of the two donor DNAs was facilitated by knowledge of their primary structures[2,10]. Both DNAs possess a unique cleavage site for the restriction endonuclease *Pst*I at which they can be joined to maintain the correct reading frame (Fig. 2). In the *amp*^{r} gene the *Pst*I site is situated approximately two-thirds towards the end. In RGH cDNA the corresponding site occurs a few base pairs distal to the

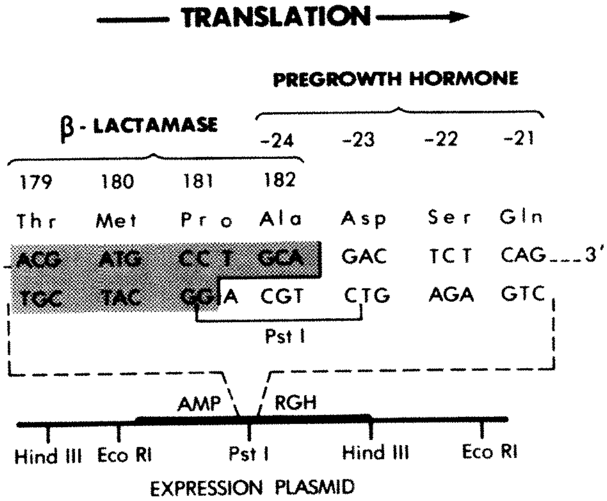

Fig. 2 Postulated nucleotide sequence around the *Pst*I site in the hybrid gene. The *Pst*I site is at the fusion between the *amp*^{r} gene sequences[10] and the cloned RGH cDNA[2]. Positive numbers refer to amino acid residues of pre-β-lactamase and negative numbers to those of the RGH pre-sequence.

initiator codon for the pre-peptide. The resultant new gene should code for a chimaeric protein of 395 amino acids (molecular weight $\sim$44,000) containing the N-terminal 181 amino acids of the β-lactamase precursor covalently linked to 214 residues of rat pre-GH. As this fusion protein carries the signal peptide of β-lactamase, it seems possible that it might be transported to the periplasmic space. Such an extracellular location might minimise possible protease attack and facilitate isolation.

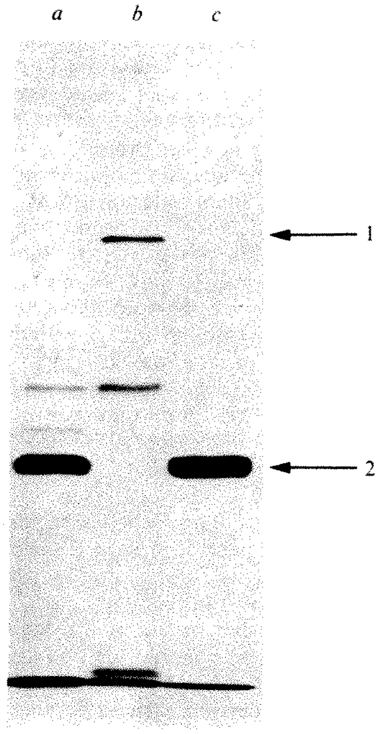

Fig. 3 Proteins synthesised from plasmids pEx-RGH and pBR322. The minicell-producing *E. coli* strain P678-54 (ref. 13) was transformed with pEx-RGH or pBR322 by standard methods[2]. A culture of each (200 ml) was grown to the late log or stationary phase of growth ($A_{650} = 0.7$) in L broth containing 0.5% glucose. Minicells were purified by repeated zone sedimentation through 5–25% sucrose gradients as described elsewhere[12] and resuspended in 2 ml of leucine- and methionine-free M-9 salts medium. After 30 min preincubation at 37 °C, 250 μCi of ^{35}S-methionine and 50 μCi of ^{3}H-leucine were added to both cell preparations, which were then vigorously shaken for 30 min at 37 °C. After a 30-min chase period with 400 μg of nonradioactive methionine and leucine, the minicells were pelleted by centrifugation at 8,000*g* for 2 min and half the cells of each preparation were lysed in 200 μl of SDS sample buffer[14]. The second half of each minicell preparation was used to isolate the proteins secreted into the periplasmic space as described elsewhere[15]. Labelled proteins isolated from equivalent amounts of minicells were electrophoresed on a 10% polyacrylamide–SDS gel[14] and identified by autoradiography of the dried gels. Lanes *a* and *b* represent the total proteins synthesised by pBR322 and pEx-RGH, respectively. Lane *c* reflects the proteins secreted into the periplasmic space of minicells carrying pBR322. Arrow 1 refers to the location of the fusion protein and arrow 2 indicates β-lactamase.

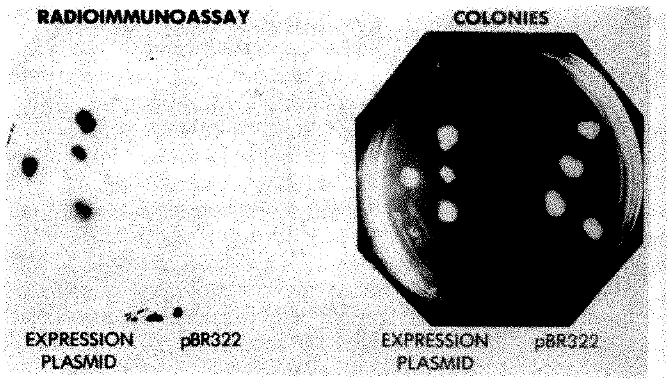

Fig. 4 Immunological detection of RGH sequences in bacteria. Bacterial colonies containing the constructed expression vector pEx-RGH were assayed for the presence of RGH sequences using a modification[16] of the solid-phase immunological screening method Broome and Gilbert[17]. The described wash buffer was replaced with phosphate-buffered saline (0.1 M NaCl, 0.025 M potassium phosphate, *p*H 7.4) containing gelatin (10 mg ml^{-1}) and NP40 (0.1%). Bacterial colonies of *E. coli* strain P 678-54 (ref. 13) carrying pEx-RGH or pBR322 were grown on L-broth agar[18] in Petri dishes. A photograph of such a plate is shown on the right. After treatment (20 min) with chloroform vapour the colonies were exposed to polyvinyl strips coated with antiserum to RGH. Strips were then soaked in the modified wash buffer (see above) to minimise binding of IgG in the subsequent reaction. The strips were then incubated overnight at 4 °C with affinity column-purified ^{125}I-anti-RGH IgG (10^{6} c.p.m., specific activity $\sim$5.3 μCi per μg), washed, and exposed to X-ray film. An autoradiogram is shown on the left.

To enable selection of plasmids carrying the correct hybrid gene, the cloned GH cDNA (originally isolated in plasmid pBR322) was first transferred from the *Hin*dIII site of pBR322 into the homologous site of pMB9, a closely related plasmid which lacks the amp^r gene. In the resultant recombinant plasmid (pMB9-RGH) the gene for tetracycline resistance is expressed at reduced levels[11]. One such plasmid which contains the GH cDNA inserted in the orientation shown in Fig. 1 was used as the recipient of amp^r gene sequences. Replacement of the unique *Pst*I–*Bam*HI fragment in pMB9-RGH with that from pBR322 should place the coding sequences for rat GH under control of the amp^r gene and will at the same time restore a fully functional tet^r gene (see Fig. 1). Thus, this fragment replacement enabled selection of bacterial colonies carrying the expression vector 'pEx-RGH' by their ability to grow on high levels of tetracycline.

Gene expression

Purified minicells[12] were used for the study of proteins encoded by the expression vector pEx-RGH. Proteins were analysed by SDS–polyacrylamide gel electrophoresis and compared with those encoded by pBR322 (Fig. 3) and pMB9 (data not shown). As anticipated, the two polypeptides pre-β-lactamase and β-lactamase which are synthesised in cells carrying pBR322 are not made from pEx-RGH. The expression vector codes uniquely for a polypeptide (Fig. 3, lane *b*, arrow 1) with an apparent molecular weight (46,000) within error limits of that expected for the hybrid protein. A comparison of band intensities (corrected for cell number) from several experiments similar to that described in Fig. 3 suggests that the 46,000 MW protein is produced in substantial quantities from pEx-RGH, although in lower amounts (about one-fifth) than β-lactamase from pBR322. When proteins released after the formation of spheroplasts in high osmotic pressure medium[15] were analysed by gel electrophoresis, a large portion of β-lactamase (Fig. 3) but not of the pEx-RGH specific product was detected. The same situation applied when material from media of whole cells was examined (data not shown). Thus, contrary to the case with β-lactamase, the 46,000 MW protein was present only in very small amounts in the periplasmic space if at all.

Immunological detection of growth hormone synthesised by bacteria

Escherichia coli colonies containing pEx-RGH were screened for their content of RGH using a modification[16] of a solid-phase munological method[17] (Fig. 4). Briefly, colonies were lysed *in tu* with $CHCl_3$ and any RGH sequences present in the cells ere bound to a polyvinyl disk coated with IgG purified from tiserum to RGH raised in monkeys (see ref. 16 for details on eparation of antiserum). Bound antigen was then specifically belled with highly purified ^{125}I-anti-RGH IgG (see legend to ig. 5) and colonies producing RGH were visualised by toradiography. As shown in Fig. 4, colonies containing the pression plasmid were labelled with the ^{125}I-anti-RGH-IgG obe, whereas those containing pBR322 failed to do so.

Several controls demonstrated the immunological specificity f the assay for RGH and strengthened the conclusion that the ones are producing pituitary GH sequences (Fig. 5). First, lonies of the K12 strain of *E. coli* devoid of plasmid were not belled with the ^{125}I-anti-RGH-IgG probe. Second, labelling of sates of colonies containing pEx-RGH was prevented when a rge excess (250-fold) of nonradioactive GH was incubated ith radioactive probe. Third, labelling was not observed when ormal monkey serum or calf serum (data not shown) were used place of anti-RGH antiserum. Finally, ^{125}I-labelled normal onkey serum failed to label any colony from the strains escribed above (not shown).

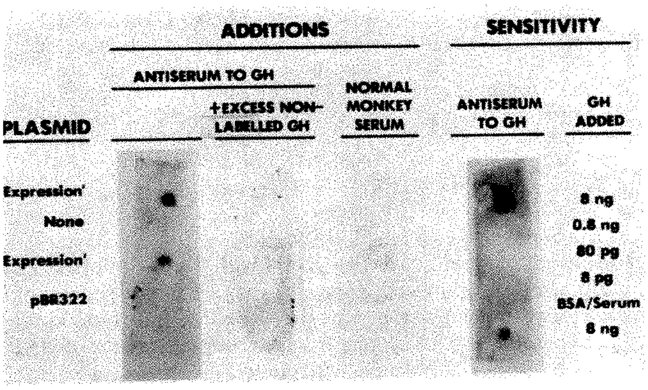

Fig. 5 Immunological detection of GH sequences synthesised by bacteria: specificity of the assay. In 'antiserum to GH', the colonies were treated as described in the legend to Fig. 4. 'None' refers to colonies of *E. coli* devoid of plasmid. In other experiments ('+ excess non-labelled GH'), a large excess (250-fold, 5 μg) of highly purified RGH was preincubated with ^{125}I-anti-RGH IgG. The autoradiograph shown in the lane 'normal monkey serum' results from using polyvinyl strips coated with normal monkey serum (in place of RGH antiserum). A slight reaction occurred with cells containing pEx-RGH, as antigen (RGH) sticks to plastic even in the absence of anti-RGH IgG. The sensitivity of the assay was measured by applying varying amounts of pure RGH (8 ng, 0.8 ng, 80 pg, 8 pg and 8 ng) to an agar plate and screening as described above.

The sensitivity of the screening procedure is indicated in Fig. 5. Labelling was observed with 8 ng, but not with 0.8 ng, of uthentic RGH added to the plate. Thus, each colony seems to ontain several nanograms of GH sequences, although further xperiments are needed to obtain better quantitation.

As indicated in Table 1, immune reactivity was also detected by direct radioimmunoassay in extracts of spheroplasts and in material from the periplasmic space. No such activity was observed in similar isolates from bacteria containing pBR322.

Discussion

In the present studies, bacteria have been genetically programmed to synthesise mammalian pituitary growth hormone sequences. Further analysis is required to assess the fidelity of such expression, the stability of the protein products, and their biological activity. The absolute quantity of GH synthesised by the bacteria cannot be determined accurately from the current studies (an estimate of 24,000 molecules per cell is obtained from the solid-phase immunoassay). However, judging from the prominence of the band in Fig. 3, it seems that sequences of RGH can be a major plasmid product. The quantity of GH present is less than that of β-lactamase; however, the study shown in Fig. 3 may result in an underestimate of the amount of GH synthesised, because in more recent studies (not shown), material of lower molecular weight (in addition to the larger molecular weight material) is specifically immunoprecipitated by antiserum to RGH but not by antiserum to bovine serum albumin. This material could consist of degradation products or the products of premature termination.

The *amp*^{r} gene was used for expressing RGH coding sequences with the hope that the mammalian hormone would be secreted by the bacteria. Such secretion might facilitate the isolation of the protein product and also protect the protein from degradation by proteases. The absence of GH sequences in the periplasmic space is surprising in view of the fact that Villa-Komaroff *et al.*[20] have recently constructed a gene suitable for the expression of rat insulin through linkage with the *amp*^{r} gene and found that the protein product was secreted[20]. It is possible that the hydrophobic region corresponding to the pre-part of RGH in the middle of the hybrid protein prevents the kind of conformation required for transport through membranes. Similarly, the overall structure of the fusion polypeptide might prevent correct processing of the precursor sequence. More detailed studies should help determine which factors, other than pre-sequence of the signal peptide protein of the hormone, are necessary for secretion.

Our findings and those of Villa-Komaroff *et al.*[20] indicate that coding sequences from higher organisms can be expressed in bacteria. Thus, it should be possible to produce biologically important peptides with the use of recombinant DNA techniques and naturally occurring structural gene sequences. Finally, the capability of expression of genes that are designed specifically or synthesised[21] should make possible the production of new hormone analogues for examining the structural requirements for agonist or antagonist activity or for therapy.

Discovery and optical identification of 2S0921 – 630

THE discovery of a faint X-ray source with the X-ray detectors on SAS 3 at a location with galactic coordinates $l^{\text{II}} \sim 282°$, $b^{\text{II}} \sim -9°$ is reported here. A subsequent optical search has revealed a likely optical counterpart in the form of a 17th magnitude star with He II 4686 and Hβ in emission. It is, therefore, likely to be a low-luminosity galactic X-ray source.

From 10 to 14 February 1978, the rotation modulation collimator X-ray detectors[1] on SAS 3 were used to search for X-ray emission from a region centred at $\alpha \sim 135°$, $\delta \sim -67°$. Data were accumulated from a total exposure of 130,000 s. The correlation maps show a previously unreported X-ray source, which we designate 2S0921 – 630 at α = 09 h 21 min 25.4 s, $\delta = -63°04'27''$ (1950 Equinox) with an error circle of radius 30″ (90% confidence). Figure 1 is an enlarged reproduction from the ESO (B) survey print with the error circle superposed. The average flux density of the source during the observation was 2.3 ± 0.3 μJy at 5.2 keV (1 μJy $= 0.242 \times 10^{-11}$ erg cm^{-2} s^{-1} keV^{-1}).

Optical observations of stars in the above error circle were made with the 3.6 m telescope of the European Southern Observatory (ESO). To search for a candidate counterpart with possible strong Hα emission, one of us (S.L.) took a direct prime-focus plate, through a 30 Å wide Hα filter, of the region of the sky centred on the error box. Star No. 5 in Fig. 1 is remarkably bright on this plate. We estimate from the ESO survey print that its photographic magnitude is approximately 17.

Spectrograms (60Å mm^{-1}) were taken (by J.v.P.) of this star with the Carnegie image tube attached to the Boller and Chivens Cassegrain spectrograph. The plates were taken on 13 March 1978, 03.33 UT and 04.07 UT and have exposure times of 40 and 20 min, respectively. IIa–O (baked) plates were used and the spectra have a widening of 0.2 mm. They cover the wavelength range from ~3,700 to ~5,000 Å. Density tracings of the spectra were made with the Faul–Coradi microphotometer of the Observatory of Utrecht. The only features clearly visible in the spectrum are a strong He II 4686 and a weak Hβ line, both in emission. Strong He II emission lines are generally present in the spectra of the counterparts of X-ray sources (see refs 2 and 3) but not usually in those of normal stars; on the basis of the above characteristics we consider star No. 5 a likely candidate for the optical counterpart of 2S0921 – 630.

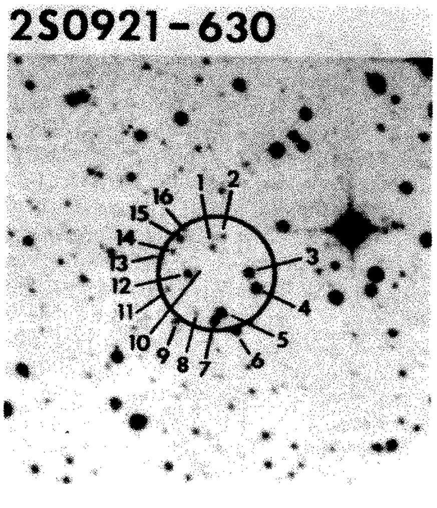

Fig. 1 Error box of 2S0921 – 630 superposed on the ESO survey print. Star No. 5 is the proposed optical counterpart.

The optical spectrum of this object is similar to the spectra of the optical counterparts of Sco X-1 and the similar galactic X-ray sources that have been discussed by McClintock *et al.*[2]. It is interesting, however, that the ratio of X-ray to optical luminosity for 2S0921 – 630 is ~10 which is much smaller than the ratios for other members of this class of counterparts which are typically of the order of 1,000. The X-ray luminosity of the sources is $\sim 6 \times 10^{35}$ $(D/10 \text{ kpc})^2$ erg s^{-1}. It may belong to the class of low luminosity galactic X-ray binaries.

We thank the staff at MIT Center for Space Research for help with this observation. Permission to use the Faul–Coradi microphotometer is gratefully acknowledged.

Simultaneous radio and X-ray observations of MXB1837 + 05 (Ser X – 1)

DURING a continuing program of radio observations of X-ray sources carried out with the NRAO very large array (VLA), we have made high sensitivity searches for radio emission from MXB1837 + 05 = Ser X – 1 (ref. 1), particularly during the SAS 3 MIT world-wide X-ray burster watch in June 1977[2]. Observations of MXB1837 + 05 were carried out on 26 April, 12 and

13 June 1977, with six 25-m antennas of the VLA operated at 4,884 MHz with system temperatures of $\sim$60 K and bandwidths of 50 MHz. Upper limits of 1 mJy were obtained for the time-averaged radio emission from Ser X$-$1 during the three periods of observation, and no short time scale radio emission was detected during or after the times X-ray bursts were observed on 12 and 13 June 1977.

The times of observations with the VLA were from 06.01 UT to 13.50 UT on 26 April 1977, from 06.15 to 13.18 UT on 12 June and from 07.04 UT to 13.14 UT on 13 June 1977. During these periods calibration sources were observed once every half hour. The VLA data were accumulated in 30-s integration intervals, and after calibration, were used to make radio maps of about 4 arc min square regions with 2 arc s resolution. The centre of each map was taken to be the position of MXB1837+05 ($\alpha(1950) = 18\text{h}37\text{min}29.8\text{s}$, $\delta(1950) = +04°59'23''$) which was known to about 20″ (ref. 3). Maps were made from various subsets of each 7-h period allowing upper limits to be set for variable radio emission on time scales from 30 s up to $\sim$7 h. On each of the three days the upper limits to the time-averaged radio emission anywhere in the fields of the map were $\sim$1 mJy. The times of major interest were the periods during and after X-ray bursts observed by SAS 3 on 12 and 13 June. The upper limits placed on radio emission during and after the bursts are a factor of 8 lower than the limits established by Johnson *et al.*[4] for X-ray bursters including MXB1837+05 and a factor of 100 lower than the limits found by Thomas *et al.* for MXB1636$-$53.

The X-ray observations were made in the 1.3–19-keV energy range with the SAS 3 horizontal tubes and xenon tube system[6,7]. Two X-ray bursts were observed during VLA radio coverage on 12 June at 11.22.20 and 13 June at 9.29.27 UT. The X-ray bursts lasted $\sim$17 s with average X-ray fluxes of 0.2–0.4 mJy. Maps with integration times of 30s, 10 min, 2 h, and 7 h were made from the radio data, with upper limits for any sources in the field of 15, 4, 1.5 and 1.0 mJy, respectively, with the shorter time periods taken coincident with or after the X-ray bursts. Exact simultaneity was achieved with the 12 June burst at 11.22.20 UT, but the 13 June burst at 9.29.27 UT occurred during a 5-min gap when a calibrator was being observed. With the limits mentioned above for the four time scales of mapping, no radio emission was observed during or after the 12 June burst and, no radio emission was observed before or after the 13 June burst.

In conclusion, even very high sensitivity radio observations cannot detect bursting X-ray sources. A clearer picture of these objects is needed, however, before the radio observations can effectively be discussed on a theoretical basis.

Interplanetary dust: are there two independent populations?

A RE-EXAMINATION of the information on the size distribution and physical properties of interplanetary dust grains as inferred from space measurements, particularly lunar microcraters, leads to the novel interpretation outlined here in terms of two independent populations. This hypothesis still suffers from uncertainties in existing data but should stimulate new experimental and theoretical work.

New data[1–5] on lunar microcraters together with the review of Fechtig *et al.*[6] have firmly established the following features of the cumulative size distribution function $F_c(D_c)$ usually represented by a D_c^{-q} power law: (1) a power index $q = 3.5$ for craters >100 μm; (2) a progressive decrease of q with decreasing diameter, starting at $D_c \simeq 100$ μm, and ending with a marked inflection point around $D_c \simeq 5$ μm; (3) a new high power index, $q = 3.1$, for microcraters smaller than $\sim$5 μm down to 0.1 μm.

The second point has already been interpreted as evidence for a bimodal population[7]. The third point was recognised only recently[1,4] when it was realised that accretionary particles and ejecta resulting from larger impacts are extremely efficient in masking the smallest microcraters. Note that microcraters with diameters as small as 0.05 μm have been observed[8]. The ratio of crater depth to crater diameter, P/D_c, offers a direct means of probing the density of impacting micrometeorites: although they are still limited to simple experimental conditions, calibrations have shown that P/D_c assumes well defined values characteristic of the density of the projectile[9,10] (Fig. 1). However, due to conflicting results[11], no clear conclusions have been reached on this matter. For instance, Brownlee *et al.*[7,12] and Mandeville[13] found a mean density of approximately 3 g cm^{-3} whereas Smith *et al.*[10], Durrani *et al.*[14], and more recently Nagel *et al.*[2] detected up to three densities: 1, 3 and 8 g cm^{-3}. On the basis of a global study of the published data regrouping 256 microcraters, we propose a clarification of this contradiction as the result apparently depends on the crater sizes (Fig. 1). In particular, by separating them into different size ranges, we found that the apparent contradictory data of Brownlee *et al.*[7,12] and Smith *et al.*[10] were in satisfactory agreement.

From our analysis (Fig. 1), the following conclusions can be put forward. First, low density grains ($\leqslant 1$ g cm^{-3}) are not detected; second, two families coexist, the large grains having, exclusively, densities typical of silicates and the small ones densities typical of metals with a minor component of the first family. In the intermediate range ($1 < D_c < 10$ μm) the two families are mixed. It is precisely in this range that the cumulative distribution function F_c presents an anomalous behaviour (inflection point) which was an indication for a bimodal population[7]. The *in situ* measurements performed by the Pioneer 8 and 9 and Helios 1 space probes have also conspicuously shown two families of dust grains; the first consists of large grains travelling on nearly circular orbits, whereas the second is composed of small grains, commonly named β-meteoroids[17], leaving the Solar System in hyperbolic orbits[15,16]. Doppler shifts measurements in the Zodiacal Light Spectrum[18] have confirmed the existence of both types of orbits. The separation between these two families again takes place for particle sizes in the μm range. Collection experiments of extraterrestrial particles performed by Brownlee *et al.*[19] during stratospheric flights have revealed two distinct kinds of grains: (1) large compact aggregates of submicronic grains having chondritic abundances and a mean density of 2 g cm^{-3}; (2) smaller, homogeneous, nearly spherical 'iron–sulphur–nickel' (FSN) grains.

The cumulative flux $F(s)$ of interplanetary dust versus grain diameter may be obtained from $F_c(D_c)$, provided the time of exposition and the calibrations of the ratio D_c/s are known. From the work of Morrison and Zinner[1] on sample 12054,54, we used a time of $1.75\times10^5 \pm 5\times10^4$ yr and a constant value $D_c/s = 2$ from the calibration of Mandeville[20] and Bloch *et al.*[21] to obtain the result presented in Fig. 2.

All the above results are therefore coherent with a two-component model of interplanetary dust: Population 1 consists principally of large grains ($s > 2$ μm) of density typical of silicates or chondritic materials (2–3 g cm^{-3}) in nearly circular orbits while Population 2 consists of small grains ($s < 2$ μm) with typically metallic densities (8 g cm^{-3}) in hyperbolic orbits. The dip observed in $F(s)$ (Fig. 2) is readily interpreted as the gradual disappearance of Population 2 which is more evident on the differential size distribution sketched in Fig. 3.

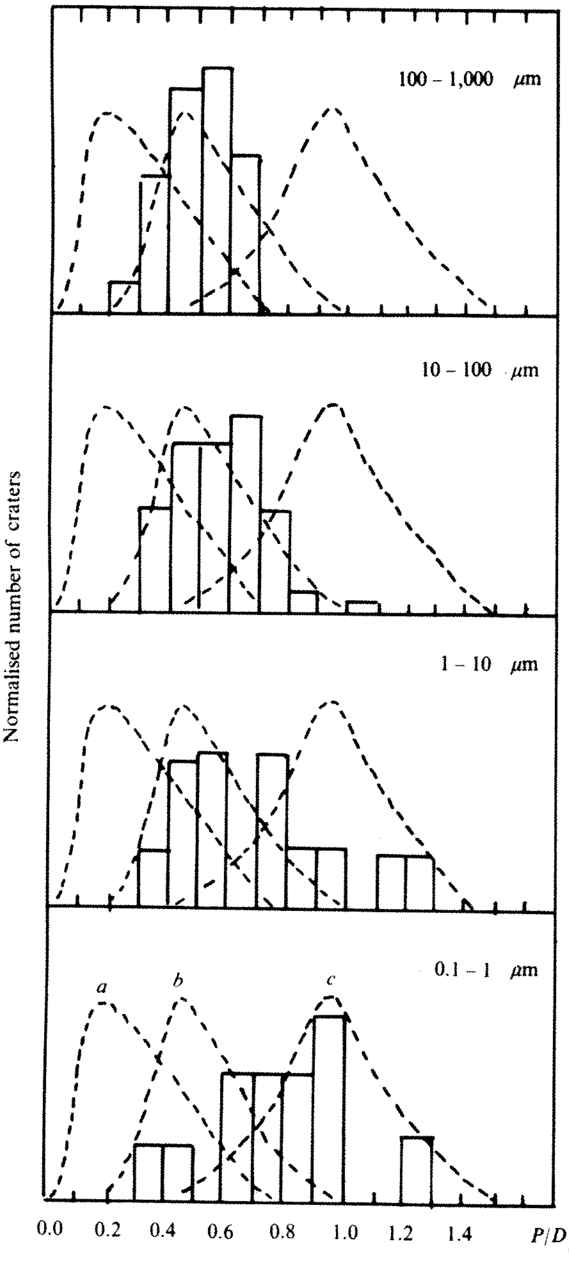

Fig. 1 Normalised histograms of the values of the ratio P/D_c for 256 craters separated in four diameter ranges as indicated. Superimposed (dashed lines) are three simulation curves corresponding to three different densities of impacting projectile. *a*, 1 g cm^{-3} (polystyrene); *b*, 2.7 g cm^{-3} (aluminium); *c*, 7.8 g cm^{-3} (iron).

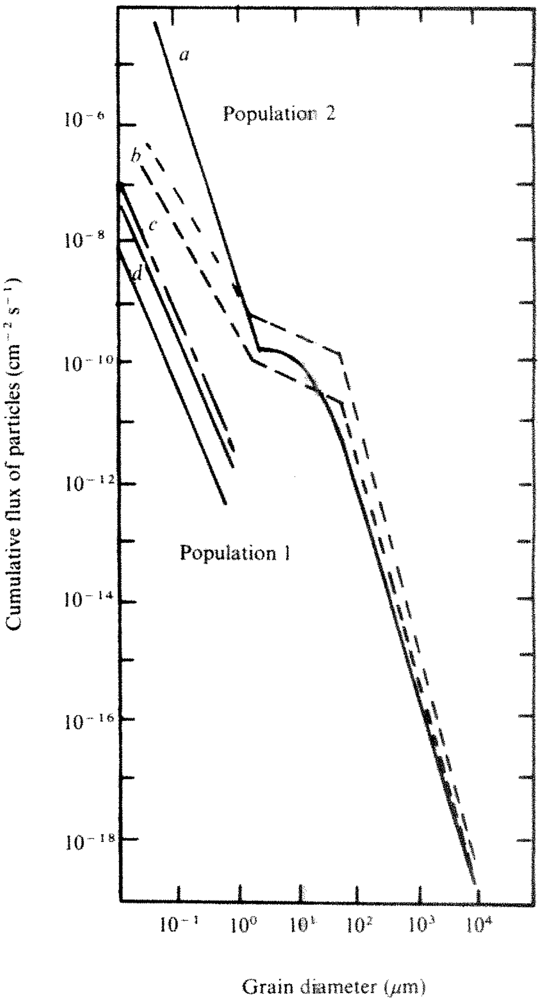

Fig. 2 Cumulative flux plotted against diameter of the particles arriving on the moon: *a*, present result; *b*, results of Fechtig *et al.*[6]; *c*, result derived from the conservation of mass flux; *d*, result from the collisional model[26].

There have been attempts to explain the origin of β-meteoroids[17,22] (which we identify with Population 2) based on the collisional fragmentation of larger grains (Population 1) within 1 AU and repulsion of the submicronic fragments under the radiation pressure force. The different physical nature of the two populations deduced from lunar microcraters casts some doubt on this interpretation which may be further rejected on the basis of the conservation of mass flux, an argument which bypasses the difficulties inherent in collisional models of grains (lack of direct calibrations).

Following the model of Zook and Berg[17], Population 1 grains are supposed to spiral slowly towards the Sun under the Poynting–Robertson effect: they may be considered to travel in nearly circular orbits and to collide because of different inclinations. If $f(s) = -\mathrm{d}F(s)/\mathrm{d}s$ denotes the differential flux of grains measured on the Moon, the spatial density is $f(s)\,\mathrm{d}s/\langle V\rangle$ where $\langle V\rangle$ is the mean velocity of the grains. The inward drift yields a radial velocity[23] $V_{PR}(s)$ leading to a radial flux of grains:

$$V_{PR}(s) f(s)\,\mathrm{d}s/\langle V\rangle$$

The total mass influx at 1 AU is therefore

$$\Phi_1 = \frac{\pi}{6}\frac{\rho}{V}\int_{s_{1,\min}}^{s_{1,\infty}} s^3 V_{PR}(s) f(s)\,\mathrm{d}s$$

where ρ is the density of the grains, $s_{1,\min} \simeq 2$ μm is the minimum diameter, and $s_{1,\infty}$ is the maximum diameter of Population 1 grains.

The situation is entirely different for Population 2 grains for which the radial velocity is of the order of the orbital hyperbolic velocity. The total mass outflux at 1 AU is simply

$$\Phi_2 = \frac{\pi}{6}\rho \int_{s_{2,\min}}^{s_{2,\infty}} s^3 f(s)\, \mathrm{d}(s)$$

where $s_{2,\min} \simeq 0.01$ μm is taken as the minimum size of Population 2 grains and $s_{2,\infty} \simeq 2$ μm as the maximum size. The final value of Φ_2 is not sensitive to this choice of parameters. The collisional hypothesis requires

$$\Phi_1 \geqslant \Phi_2$$

while we found

$$\Phi_1 \simeq 5\times10^{-23}\ \mathrm{g\ cm^{-2}\ s^{-1}} \quad \text{and} \quad \Phi_2 \simeq 5\times10^{-20}\ \mathrm{g\ cm^{-2}\ s^{-1}}$$

The difference between the two fluxes is so large that our present conclusion will not be affected by any possible variations of the parameters involved in the calculation (grain density, orbital velocities) not by uncertainties in the exposure time which do not affect the ratio Φ_1/Φ_2. Using the above value of Φ_1, we can give an upper limit for the flux of fragments resulting from collisional destruction under the constraint $\Phi_2 = \Phi_1$ assuming further that (1) all grains of Population 1 are destroyed and all fragments smaller than 2 μm are ejected on hyperbolic orbits; (2) the distribution of fragments follows a power law $s^{-\eta}$ where $\eta = 3.48$ (refs 24, 25). The result is shown in Fig. 2 and is three orders of magnitude smaller than the observed flux. We constructed an elaborated collisional model[26] using the basic procedure of Dohnanyi[22] but incorporating as many real data as possible[19,25]. The model fluxes of fragments always lie slightly under the upper limit deduced from the conservation of mass flux. If one accepts the present results from lunar samples and space experiments, we arrive at the conclusion that the two populations are entirely independent on several grounds: size, density and dynamics.

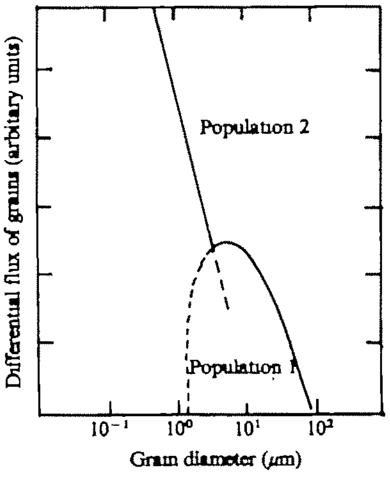

Fig. 3 Differential flux of particles as a function of particle diameter (arbitrary units)

Population 1 has probably its origin in dust grains ejected by short period comets. The sizes and size distribution law are in surprisingly good agreement with those derived for Comet d'Arrest[27]. The bulk of Population 1 grains probably disappear within 1 AU as the value of β (ratio of the radiation pressure to the gravitational forces) for silicates[28] and the 'initial' orbital conditions at 1 AU (nearly circular orbits) ensure that they will not escape the inner region of the Solar System whatever processes (collisions, sublimation) they undergo. We may therefore consider that Φ_1 corresponds to the mass loss rate of Population 1. Integrating Φ_1 taking into account the distribution of inclination[22], we found a mass loss rate of 2.8×10^4 g s^{-1}. To maintain Population 1 in steady state, approximately 70 short-period comets similar to Comet d'Arrest is required on the basis of an average production rate of 400 g s^{-1}. Note that this satisfactory number is obtained assuming a grain albedo of 0.5, a more reasonable value than the 0.001 considered by Sekanina and Schuster[27]. Population 2 presents far more difficult problems. Either the grains are formed in the solar atmosphere and subsequently expelled by radiation pressure[29] (although this presents difficulties[30]) or they are still contained in larger bodies when they penetrate inside 1 AU. Long-period comets could be a possible source as they are known to be very dust productive. However, the existence of only prograde hyperbolic orbits[18] seems to rule out this solution to a large extent.

Is the Sun almost-intransitive?

THERE is now ample instrumental, historical and proxy evidence for palaeoclimatic variability over time scales ranging from 10 to 10^9 yr (ref. 1). Although a great deal of research is still needed to establish more precisely the nature and finer spatial and temporal resolution of these changes, the main theoretical problem is to understand the mechanisms responsible for this variability over such a wide range of time scales. We suggest here that if the Sun were almost-intransitive, it could explain some of this climatic variability. Many hypotheses have been advanced by researchers in various disciplines based on physical processes, both terrestrial and extra-terrestrial[1–8], and although there is no general consensus as to the causes of variability over various time scales, the common view among climatologists is that the very long time-scale fluctuations with periods of ~10^8 yr can be explained by causes of terrestrial origin, such as the changes in oceanic and continental geometries[3,10]. The intermediate time-scale fluctuations with periods of $\sim 10^4$–10^5 yr are thought to have been caused by variations in Earth's orbital elements[9]. The relatively short time-scale fluctuations with periods of $\sim 10^2$–10^4 yr are, on the other hand, hard to explain, because of the clear lack of a physical process with the appropriate time scale. Solar variability is, however, accepted as a serious contender[3,10]. All these hypotheses, whether terrestrial or extra-terrestrial, have in common the assumption that the changes in climate are deterministic, that is, they are a causal response of the climatic system to a change in some environmental (internal or external) parameter, even though the actual mechanism of change is not usually understood.

A radically different hypothesis by Lorenz, suggests that the climatic variability over some time scales may turn out to be non-deterministic[14–16]. This possibility arises, essentially, from the fact that the climate can be defined as a set of long-term statistics of the time-dependent solution of a set of appropriate non-linear differential equations. On the basis of ergodic theory, both transitive systems (ones in which long-term statistics of some time-dependent solution is independent of the choice of boundary conditions) and intransitive systems (ones in which the solution is dependent on the choice of the boundary conditions) can exist[16]. Evidence for intransitive systems also exists both experimentally[17] and numerically[14]. In addition to the above two modes of behaviour for a system, Lorenz has pointed out the possibility that a system of non-linear differential equations may have solutions which exhibit different statistical properties within different segments of a long time span, with a completely constant environment. Such systems he has termed almost-intransitive[14–16]. As an example of these systems, he has constructed numerical models (which to some extent resemble the numerical models of the Earth's atmosphere, or for that matter any similar non-linear system of differential equations), which behave in an almost-intransitive fashion[16].

There is also some evidence to suggest that the climate may have behaved in an almost-intransitive fashion over time scales with periods of $\sim 10^4$ yr (ref. 18). It may, therefore, seem likely that the possible almost-intransitivity of the climatic system could account for climatic variability over such time scales, without the need to invoke solar variability. This, however, does not seem to be the case, as there are strong indications of solar variability over these time scales, both historical[12] and proxy. The latter evidence is based on the measurements of radiocarbon(^{14}C) fluctuations in tree rings which are thought to have been caused by the solar modulation of galactic cosmic rays[11]. There is also some apparent correlation between the radiocarbon variations and the historical climatic record[10,11,19,20]. Solar variability over such time scales cannot, therefore, be ruled out in favour of almost-intransitivity of the climatic system.

There is, however, some difficulty in accounting for the solar variability over these time scales. This becomes apparent when one takes a closer look at the commonly accepted solar model (with its own difficulties[21]), and the time scales characteristic of the physical processes that are thought to be operative in the Sun. Such examination reveals a spectrum of time scales dominated on one end with very long time scales of $\sim 10^7$–10^{13} yr, and on the other with very short time scales of $\sim 10^{-4}$–10^{-1} yr (ref. 13). Therefore within the context of the presently accepted solar model, the time scales of variability for which there is some evidence and are thought to be important climatologically, namely those with periods of $\sim 10^2$–10^4 yr, are hard to explain. It therefore seems to be necessary to reconcile the evidence for solar variability over such periods, the lack of physical processes with appropriate time scales operative in the Sun and the possibility of the existence of systems which behave almost-intransitively.

We suggest that this could be achieved if the Sun itself (its coupled 'convective zone-atmosphere') were almost-intransitive. Some of the arguments that support the plausibility of this hypothesis and some of its consequences are given below.

The complete, unapproximated fluid dynamical equations representing the convective zone-atmosphere of the Sun are highly non-linear and are very similar to those representing the Earth's atmosphere. Lorenz's arguments regarding the plausibility of the almost-intransitivity of the climatic system could therefore equally apply to the Sun, or to any physical system where similar highly non-linear differential equations are operative.

Almost-intransitivity of the Sun could account for the evidence of solar variability in radiocarbon data and in the historical record, and also the climatic variability over these time scales. Almost-intransitivity of the climatic system on the other hand, although possible, cannot account for the independent evidence for solar variability over such time scales.

There is also the possibility, on the basis of dishpan experiments[17] with their limited similarity to the climatic system, that the climatic system may be intransitive[16]. If so, it is hard to switch from one climatic regime to another without the presence of an external forcing mechanism[16]. Almost-intransitivity of the Sun could act as such an external forcing agency.

It seems plausible therefore that the Sun could be almost-intransitive over some time scales. It should, however, be added that the climatic system is highly non-linear and complicated, and it is possible that even if the Sun is almost-intransitive, this need not be the sole cause of climatic variability over such time scales. Nevertheless, if the Sun turns out to be almost-intransitive it could have astronomical as well as climatological significance.

I thank my colleagues at the Climatic Research Unit and at Queen Mary College, London for their encouragement, and the US Office of Naval Research for grant No. 0014-77-9-0074.

Waves in narrow channels: faster capillary waves

DURING experiments on the propagation of water waves in channels with parallel sides made of Perspex, it was found that the phase velocities of small-amplitude waves with wavelengths in the range 40–100 mm were consistently higher than predicted by the standard hydrodynamic theory[1,2]. The original observations of this anomaly were made in a channel 100 mm wide filled to a depth of 50 mm. For these none too small dimensions, the standard theory might be expected to provide a close approximation to the wave velocity, but velocities $\sim 0.5\%$ too high were observed. Highly surface-clean water and clean apparatus was used in all the experiments, and with these

0028–0836/78/0276—0803$01.00

precautions the measurements proved to be wholly reproducible, prompting a closer examination, which is described here, of the wave motion to detect the cause of the anomaly. It was seen that the lines of contact between the water surface and the sides of the channel did not in fact rise and fall in step with the movement of the surface at the centre of the channel, instead remaining fixed in their original locations with the water at rest.

The observed immobility of the contact lines exemplifies the phenomenon commonly called contact-angle hysteresis. A larger contact angle is apparent when a liquid is advancing over a solid surface than when it is receding; and correspondingly, for a static contact line, there is an intermediate range over which the angle can vary to counterbalance forces tending to dislodge the line. This hysteresis, which often spans a sizable fraction of the mean contact angle, may be observed easily with almost every practical (non-reacting) combination of liquid and solid, and it is usually due to either microscopic roughness or chemical inhomogeneity of the solid surface.

With regard to experiments such as ours, therefore, it is reasonable to conclude that contact lines will remain fixed, provided the wave amplitude does not exceed a certain threshold. The vibrating surface of the water will then curve like a membrane tied at its edges, and the capillary pressures associated with the additional, transverse curvature will evidently stiffen the surface, so increasing the velocity of wave propagation. Further experiments were made using much narrower channels, for which the stiffening effect was expected to be correspondingly greater, and phase velocities were recorded that were remarkably higher than those of the more familiar, long-crested waves in the same range of wavelengths. For example, in a channel 4 mm wide filled to a depth of 25 mm, the phase velocity of waves 100 mm long was found to be about 2.5 times the predicted value for waves of the same length free from edge constraints.

A linearised theory for the new class of wave motions has been developed, focussing on the case of an exactly brimful channel. An advantage of this case as a theoretical model is that the free surface is flat when at rest, so that evaluation of the capillary pressures on the perturbed surface is comparatively simple. It also has considerable practical advantages, in particular that the contact lines can be located securely along sharp edges of the channel and that the required flatness of the free surface can be judged accurately by viewing the mirrored images of distant objects; accordingly, it was made the subject of the final, most exacting series of experiments devoted to these waves. Other assumptions of the theory apparently compatible with the experimental conditions are that the liquid is incompressible and inviscid, so that its motion started from rest is irrotational, and that the liquid has a constant surface tension.

The theory is more complex than the corresponding theory for waves free from edge constraints; and even in the simplest case where the channel has a rectangular cross-section, explicit solutions are not available. As usual in water-wave theory, the hydrodynamic loading of the perturbed free surface can be represented abstractly by a Neumann boundary-value problem, but the edge conditions imposed on functions representing the displacement of the free surface imply that no finite combination of the eigenvectors of this constituent problem can solve the complete problem including the effects of surface tension. A variational formulation leads, however, to a well-defined expression, in the form of a Rayleigh quotient, for the possible frequencies of waves with prescribed wavelength, and this result served both to establish that the complete problem has solutions in appropriate function classes and to give useful estimates of wave properties.

It seems that the system, like the simpler one without edge constraints, has a fundamental wave mode which can propagate at any given frequency, and which for a given wavelength has the lowest possible frequency. Higher modes have respective cut-off frequencies, which are the frequencies of standing waves independent of distance along the channel, and below which propagation is impossible. For each of the higher modes, the phase velocity is unbounded and the group velocity is zero in the limit as frequency approaches the cutoff value from above. As might be expected, the fundamental mode uniquely has the property that the edges and perpendiculars to them are its only nodal lines: in the cross-section through a longitudinal wave crest, the elevation of the free surface above its undisturbed level is symmetrical about a maximum at the centre, vanishing only at the edges. A less obvious fact emerging from the theory is that at the edges the curvature of the free surface is generally not zero, vanishing only where there is a spanwise nodal line.

For comparison with the experimental results, the theoretical relationship between frequency and wavelength was estimated by means of the Rayleigh–Ritz method, which is particularly amenable in the relevant case of rectangular channels. Taken to two stages of approximation, the method gave results for the fundamental mode in very satisfactory agreement with experiment, and such is the efficiency of the method that even the roughest, first-order estimates seemed to be close to the true values. For example, applied to channels whose breadth, b, is less than ~20 mm and whose depth, h, is not less than b, the following formula gives a good estimate of the fundamental phase velocity, c_1, as a function of wave-number α ($=2\pi$/wavelength):

$$c_1^2(\alpha)=\frac{1.2(g+\gamma\alpha^2)+12\gamma b^{-2}}{\alpha\{\coth(\alpha h)+0.03050(\alpha b)-0.000376(\alpha b)^3\}}$$

Here g is the gravity constant, and γ is the ratio of surface tension to density. This formula is obtainable simply by taking the spanwise distribution of the oscillatory surface displacement to be proportional to $f(x)=(x/b)-(x/b)^2$, where x is the distance from one edge, substituting the function f in the Rayleigh quotient whose absolute minimum expresses $\omega_1^2=\alpha^2c_1^2$, and introducing certain elementary inequalities satisfied by the infinite series whose sum is the denominator of the quotient. The theory proved the formula to be a strict upper bound for $c_1^2(\alpha)$, and it should be particularly close to the true value when αb is much smaller than 1. Over the range of our experiments, the values of $c_1(\alpha)$ predicted by it were at most about 3% in excess of the measured values. Note that in the long-wave limit $\alpha\rightarrow 0$, the estimate is $c_1^2(0)=(1.2g+12\gamma b^{-2})h$, whereas the corresponding well-known result for waves without edge constraints is $c^2(0)=gh$.

Figure 1 presents values of wavelength measured in two channels with different rectangular cross-sections, and also includes theoretical curves for the fundamental mode respective to the two sets of experimental conditions. The Perspex channels, each having a working length of about 1 m and an additional length of about 450 mm with a beach to absorb the waves, were filled exactly to their brims which had been machined smooth. Waves were excited at constant frequency by a small oscillating paddle (made of PTFE) which was driven by an electrodynamic vibrator, and the range of frequencies employed was such that only waves in the fundamental mode would propagate away from the wave-generator. Relative to the original electronic signal driving the motion, variations in the phase of the waves with distance along the channel were monitored by means of a capacitance probe which could be continuously positioned at a fixed height above the water surface, and wavelengths were measured by observing the distances between positions of coincident phase, indicated by Lissajous figures on an oscilloscope.

On the whole the new theoretical results are in good agreement with the experimental observations, although the measured phase velocities tend to be slightly less than those predicted. This discrepancy is in the right direction for it to be accountable in part to the residual error implicit in the use of the Rayleigh–Ritz method, but another possible reason for it can be linked to the difficulty of ensuring a perfectly clean water surface in the channels. Their narrowness made them more or less inaccessible for careful cleaning except by high-speed water jets, and measurements of surface tension *in situ* were impracticable. The water used in the experiments was unable to sustain surface bubbles after being shaken, thus passing a sensitive test for the absence of surface-active contamination, and it was put into the channels by a glass pipette which had been cleaned with chromic acid. As used in the calculations, the value of surface tension was taken to be that for the supply of surface-clean water.

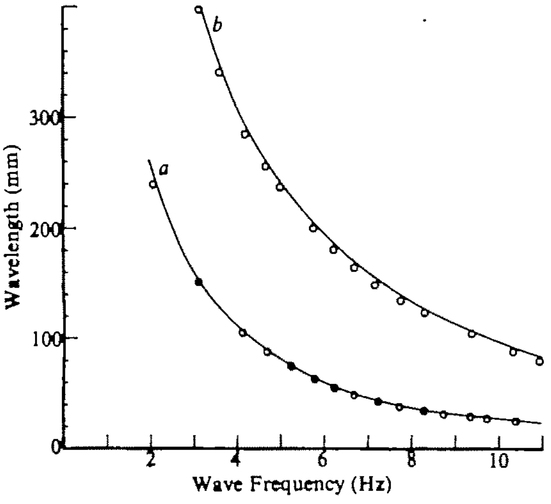

Fig. 1 Measured values of wavelength as a function of frequency, for water waves of small amplitude in two channels: *a*, width 20.3 mm, depth 21.5 mm; *b*, width 4.0 mm, depth 25.0 mm. The solid curves were calculated by the Rayleigh–Ritz method taken to two stages of approximation. Surface tension was estimated to be 72.0 mN m^{-1}.

Contamination subsequently picked up, however, would have had effects consistent with what was actually observed. The discrepancy between measured and predicted wave properties did in fact tend to increase gradually during experimental runs, consistently with a gradual decrease of surface tension.

Capillary wave phenomena depending on edge conditions of this kind seem to have attracted little previous attention and many problems akin to the present one may be suggested for theoretical as well as experimental study. The most promising candidate is perhaps the case of standing waves in closed basins, whether brimful or with fixed contact lines supporting upwards or downwards curving menisci. The nonlinear theory of progressive waves with moderately large amplitudes also poses certain challenging problems. A fuller account of our investigation including a rigorous treatment of the theoretical problem posed by the new class of water waves will be published elsewhere[3].

SSTs, nitrogen fertiliser and stratospheric ozone

THE threat to stratospheric ozone from supersonic transport (SST) exhaust emissions has been a subject of controversy since Hampson[1] first suggested that significant ozone reductions might be caused by discharged water vapour. Later, after Johnston[2] and Crutzen[3] pointed out that even larger ozone depletions might result from emitted nitrogen oxides, water vapour effects were considered to be relatively unimportant. In the intervening years, predictions of SST ozone modification have evolved with advancing scientific knowledge[4–7]. Using a recently revised model of the stratosphere[8], we report here that a substantial ozone layer enhancement could accompany worldwide SST fleet operations, and that water vapour may be an important factor in SST assessments. We have also found that increased nitrogen fertiliser use might, likewise, enhance the ozone layer, in contrast with previous calculations of ozone reduction[9–11].

Zahniser and Howard[12] have just reported the first direct measurement of the rate coefficient for the reaction

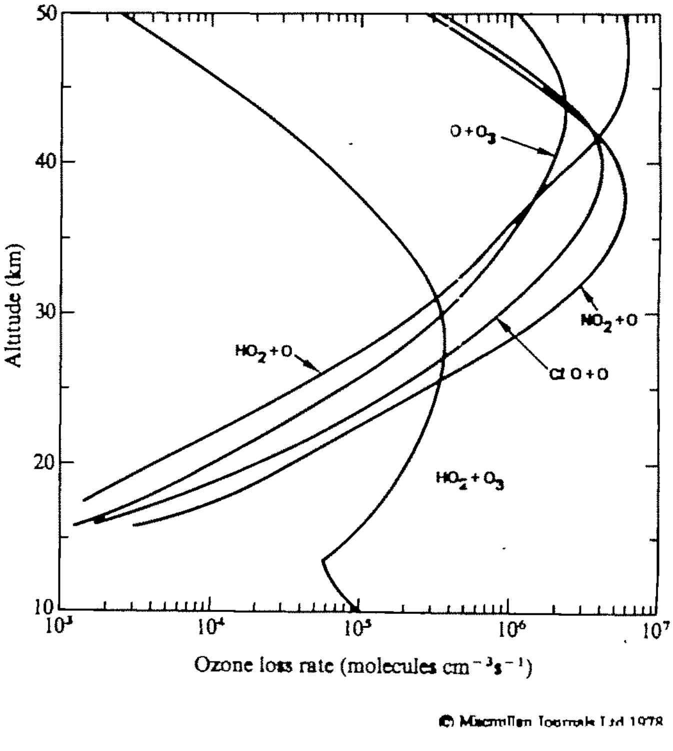
$$HO_2 + O_3 \rightarrow OH + 2O_2 \qquad (1)$$

Their result, $(1.4 \pm 0.4) \times 10^{-14}\ e^{-(580\pm100)/T}$ cm^3 s^{-1} is, at stratospheric temperatures, a factor of 4–6 larger than earlier values, which were based on reaction rate ratios[13]. In the lower stratosphere, where most terrestrial ozone resides, reaction (1) accelerates ozone destruction through a catalytic chemical cycle that also involves the reaction

$$OH + O_3 \rightarrow HO_2 + O_2 \qquad (2)$$

Figure 1 gives the rates of chemical destruction of odd-oxygen (essentially ozone) in the unperturbed stratosphere due to the dominant catalytic reaction cycles involving hydrogen radicals (HO_x = OH and HO_2), nitrogen oxides (NO_x = NO and NO_2), free chlorine gas (Cl_x = Cl and ClO), and the Chapman reactions among the oxygen allotropes. The few chemical processes shown in Fig. 1 represent the most important ozone loss mechanisms in current models of the stratosphere; they are

Fig. 1 Ambient rates of consumption of stratospheric odd-oxygen (ozone) for key catalytic reactions steps.



0028-0836/78/0276—0805$01 00

responsible for more than 80% of the total ozone loss rate. A complete description of the one-dimensional model used here to make ozone calculations can be found elsewhere[14].

Note in Fig. 1 that HO_x, because of reaction (1), is now the major catalytic agent for ozone loss below 25 km; HO_x also dominates ozone loss above 40 km. Between 25 and 40 km, NO_x has the greatest influence on the ozone loss rate. The Cl_x and Chapman reactions represent important secondary odd-oxygen loss mechanisms (assuming a current atmospheric chlorine level of about 2 parts per billion by volume). The stratospheric ozone content is roughly determined by the balance between loss (as in Fig. 1) and production through O_2 photolysis. The implications for ambient ozone of the new rate constant for reaction (1) are discussed by Whitten *et al.*[15]; some of these implications had been speculated on in earlier publications[6,7].

Shortly before the completion of the Zahniser and Howard[12] study, another major change in aeronomic models occurred when Howard and Evenson[16], and Burrows *et al.*[17] redetermined the rate constant for

$$HO_2+NO \rightarrow OH+NO_2 \qquad (3)$$

The revised rate coefficient, $\sim 8\times10^{-12}\,cm^3\,s^{-1}$ at room temperature, is nearly a factor of 40 greater than previously adopted stratospheric values. The aeronomic effects of reaction (3) are complex[7,8]. Basically, the larger rate constant increases the importance of HO_x relative to NO_x as an ozone-active catalyst, which amplifies the role of reaction (1) in the ozone balance.

Supersonic aircraft cruise at heights well into the stratosphere and release NO_x and water vapour as exhaust products. In a recent detailed assessment of the potential environmental impact of future SSTs, Poppoff *et al.*[8] showed that NO released by SSTs inhibits the normal HO_x catalysis of ozone because reaction (3) diverts HO_2 from reaction (1). Added NO_x also induces faster recombination of HO_x radicals through a reaction of OH with nitric acid, although NO_x regenerates some HO_x (and ozone) through a natural smog mechanism involving methane oxidation[8]. Moreover, NO—which has a fast reaction with ClO analogous to reaction (3)—interferes with chlorine-sensitised ozone destruction. As a result of these coupled interactions, the total content of stratospheric ozone was calculated to increase slightly (a few tenths of a per cent) for modest-sized fleets of SSTs (up to several hundred planes) flying below about 25 km.

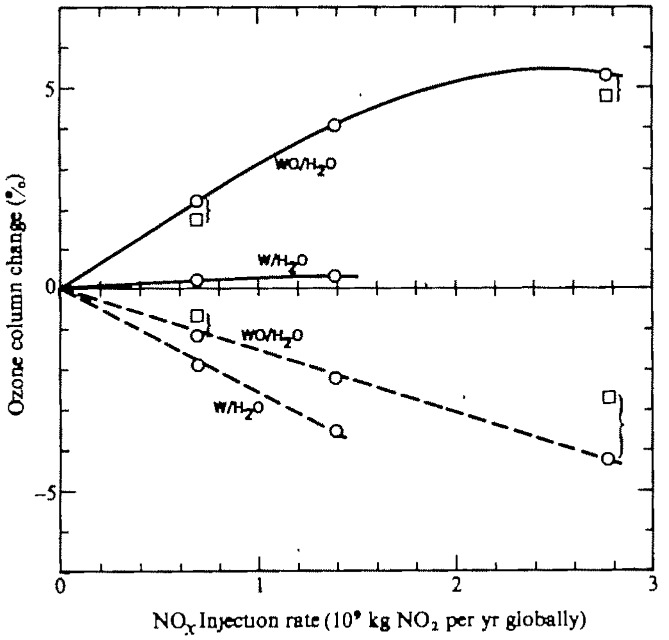


Fig. 2 Steady-state perturbations of the vertical ozone column above 10 km (solid line) and 30 km (dashed line) as a function of the rate of a steady NO_x injection at 20 km. Results are shown both with (W/H_2O) and without (WO/H_2O) simultaneous water vapour release. ○, Values computed using a Wofsy-type (WT) diffusion coefficient; □, Values computed with an alternative (DC) diffusion profile (see text).

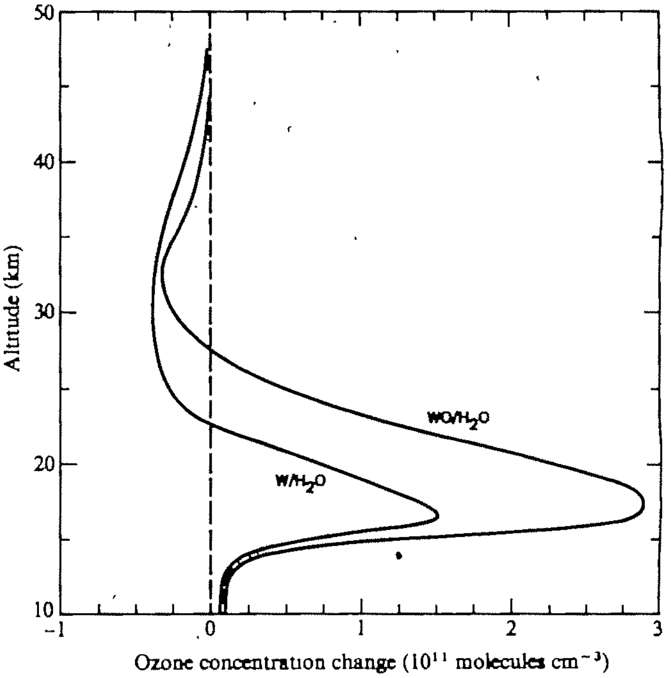

Fig. 3 Calculated steady-state stratospheric ozone concentration changes due to an NO_x injection of 7×10^8 kg NO_2 yr^{-1} (globally averaged) both with and without water vapour emission.

However, Poppoff *et al.*[8] also found that aircraft water vapour emissions may cause significant chemical degradation of ozone because of the following circumstances: (1) H_2O is the major source of stratospheric hydrogen radicals, which now dominate ozone loss throughout most of the stratosphere (see Fig. 1); (2) advanced aircraft technology can (theoretically) suppress NO_x emissions, but H_2O emissions are essentially fixed in proportion to the fuel burned. It has been proposed that ozone depletions due to stratospheric water vapour increases might be largely offset by ozone recovery resulting from H_2O infrared cooling of the air, which slows some of the ozone catalytic reactions[18]. Unfortunately, definitive thermal-feedback calculations related to SST perturbations have yet to be made.

Figure 2 gives our revised estimates of ozone column changes resulting from NO_x injection at 20 km. Two injection cases are considered: (1) NO_x injection only, and (2) simultaneous NO_x and H_2O injection assuming relative engine emission indices of 6 g NO_2 per kg fuel (a design goal), and 1.3 kg H_2O per kg fuel (stoichiometrically determined for jet fuel combustion). Both cases neglect possible thermal feedback effects. Case 2 roughly corresponds to 550 H_2O molecules released with each NO molecule (where NO is taken to be the predominant NO_x species emitted by aircraft engines).

Most of the present calculations were made with the one-dimensional model mentioned earlier using a Wofsy–McElroy type (WT) of eddy diffusion coefficient[19] with the tropopause height adjusted to 13 km (ref. 8); a few cases using a Dickinson–Chang type[20] (DC) are shown for comparison. Note in Fig. 2 that, with regard to the major effects of SSTs on ozone, the differences between diffusion coefficients are not significant. It should also be pointed out that the uncertainty in such model predictions is large[8,20].

According to our latest estimates (Fig. 2), NO_x injection alone could lead to a surprisingly large total ozone enhancement—several per cent or more. In contrast, the ozone content above

30 km would be significantly depleted. Substantial total ozone enhancements are predicted even for the largest NO_x injection rate considered, which corresponds to more than 1,000 advanced aircraft operating on a daily worldwide basis. The reason for these large ozone enhancements can be traced directly to the increased rate constants for reactions (1) and (3). That is, rapid HO_x catalysis of ozone through reaction (1) is strongly suppressed by injected NO through reaction (3), more so in our revised model than in the model used by Poppoff *et al.*[8].

When NO_x and H_2O are injected simultaneously, we still find ozone increases, albeit much smaller ones. Nonetheless, the magnitude of the chemical degradation of ozone by added water vapour is a factor of 2 larger in our updated model because of the faster rate for reaction (1). Calculated ozone changes due to added NO_x and H_2O are quite sensitive to the adopted background chlorine level (2 parts per billion by volume here). Generally, as the chlorine level rises, the ozone enhancement following NO_x injection, and the ozone decrease following H_2O injection, both become larger[8].

Figure 3 shows the predicted ozone concentration changes corresponding to the operation of about 200 aircraft at 20 km. Water vapour chemical reactions are seen to negate in large part the NO_x-induced ozone gains calculated below 25 km. The possible significance to atmospheric temperature and dynamics of such ozone alterations has never been treated satisfactorily.

In the past, the related problem of nitrogen fertiliser and sewage decomposition into free nitrous oxide (N_2O) with subsequent photochemical (NO_x) effects on ozone has been stated in terms of the per cent ozone depletion per unit increase in atmospheric N_2O (refs. 9–11). Using our revised model, however, we calculate that a 50% increase in N_2O abundances could lead to a 2.7% increase in total ozone (above 10 km, for the WT diffusivity). Even so, the ozone content above 30 km would be reduced by more than 5%.

In accordance with our latest estimates of global ozone modification due to stratospheric flight, new research emphasis should be placed on the aeronomical role of water vapour effluence at high altitude, with special regard to its photochemical impact on ozone and infrared effect on air temperature.

Precambrian solution photochemistry, inverse segregation, and banded iron formations

SOLAR radiation on an early Precambrian sea would generate short-lived excited species near the surface of the water. Many of the species would be powerful oxidising or reducing agents. Despite back-reactions, net reducing power would be lost to the atmosphere. This effect would be the opposite of present day photosynthesis and can be termed 'inverse segregation'. Its possible relevance to banded iron formation is discussed here.

Consider an early Precambrian sea on a summer's day. The atmosphere is neutral (N_2+CO_2) or slightly reducing (+also a little H_2)[1]. High energy UV sunlight (from ~200 nm) thus reaches the seawater which contains Fe^{2+} among other simple inorganic ions. Many of these absorb radiation in the 200–300 nm range, often through charge-transfer-to-solvent transitions[2–6]. As a result numerous short-lived excited species are generated in the upper few centimetres of the water, for example:

$$A^{x-}_{aq} \xrightarrow{h\nu} \cdot A^{(x-1)-} + e^-_{aq} \qquad (1)$$

$$Fe^{2+}_{aq} \xrightarrow{h\nu} (Fe^{2+}_{aq})^* \qquad (2)$$

Many of these are powerful oxidising and reducing agents and may generate others through, for example:

$$e^-_{aq} + H^+ \rightarrow \cdot H \qquad (3)$$

$$(Fe^{2+}_{aq})^* \rightarrow Fe^{3+}_{aq} + OH^- + \cdot H \qquad (4)$$

$$e^-_{aq} + CO_2 \rightarrow \cdot CO_2^- \qquad (5)$$

Exceedingly complex cross reactions and back reactions follow, but not very far below the surface only longer lived oxidised and reduced species are found. These continue to react, often with each other. They cannot fully neutralise each other, however, because during these processes some reduced species have escaped to the atmosphere. In particular H_2, but probably also CO and some of the small organic molecules formed following reactions such as (5) (ref. 6). By contrast oxidising species, particularly radicals[4], have quickly converted Fe^{2+} to Fe^{3+} which precipitates as highly insoluble ferric and ferric–ferrous hydrolysis products. For example:

$$\cdot H + Fe^{2+}_{aq} + H^+ \rightarrow Fe^{3+}_{aq}\downarrow + H_2\uparrow \qquad (6)$$

$$\cdot A^{(x-1)-} + Fe^{2+}_{aq} \rightarrow Fe^{3+}_{aq}\downarrow + A^{x-} \qquad (7)$$

There are, perhaps, still back reactions with reduced species remaining in deeper waters, but net oxidising power remains in the sediments in balance with the reducing power lost to the atmosphere. This effect would be the opposite of present day photosynthesis which puts reduced material in the ground and maintains an oxidising atmosphere. We might call it 'inverse segregation'.

From geological evidence—for Fe^{2+} in ancient seas, and from the presence of easily oxidised detrital minerals in ancient sediments—the atmosphere is widely thought to have been free of oxygen until ~2,000 Myr ago[7,8]. That was the great period of ferric sedimentation in the form of the massive and still problematical banded iron formations (BIFs)[7–10]. Typically these consist of alternate iron-rich and iron-poor layers within siliceous sedimentary rocks. The layers are generally from 0.5–3 cm thick with, frequently, 'microbands' on the mm scale or less that may, nevertheless, extend for hundreds of kilometres: the microbands have been attributed to an annual even outfall from large bodies of water[11,12]. Could inverse segregation explain these largely oxidised deposits?

It might account qualitatively for the general history of BIF sedimentation. The record starts with the oldest known sediments at 3,800 Myr ago[13,14]. As well as carbonates and BIFs, these rocks contain only very small amounts of graphite[14] suggesting that a strongly reducing methane-laden atmosphere, if it ever existed, had passed away by this time[15]. As the evolving atmosphere became still less reducing, through a continuing loss of hydrogen to space, together with diminishing volcanic sources[1]. reduced species derived from the atmosphere would less often reconvert oxidised precipitates before they reached the sediments. Hence, when the atmosphere was just neutral, inverse segregation should have been at its most effective, corresponding, perhaps, to the greatest period of the BIFs just before they became rare at ~2,000 Myr ago[8]. In the subsequent faintly oxidising regime (until ~700 Myr ago[7]) BIFs could still form, but only in special situations where water masses were fed by submarine sources of Fe^{2+} (refs 8, 10). After that, with substantial photosynthetic oxygen, an ozone screen would have prevented further large scale photoprecipitation. (The BIF record finally peters out at ~800–600 Myr ago[16].)

Quantitatively the idea also seems feasible. If we take the present solar spectral irradiance curve between 200 and 300 nm (ref. 17) and if we assume also a transparent atmosphere in this range, then about 0.03 einsteins yr^{-1} could have struck an average cm^2 of sea surface. If each photon lead to the deposition of one Fe^{3+} ion, the sedimentation rate would be ~1,700 $mg\ cm^{-2}\ yr^{-1}$. This can be compared with the range of between 8 and 43 $mg\ cm^{-2}$ for total iron (some of it Fe^{2+}) found in microbands attributed to an annual outfall[12]. Some set of photoredox processes with an overall quantum yield of ~0.005–0.02 would seem to be needed.

Quantum yields of this order are common enough for laboratory photoredox processes. One reaction that is attractive for its simplicity is the well known evolution of H_2 from acid ferrous solutions[4,18,19]; formally:

$$Fe^{2+} + H^+ \xrightarrow{h\nu} Fe^{3+} + \tfrac{1}{2}H_2\uparrow \qquad (8)$$

Using a low pressure mercury lamp with a filter to cut out radiation below 200 nm, initial quantum yields of about 0.12–0.07 were obtained over the *p*H range 1–3 with 0.02M $FeSO_4$ (ref. 4). This may seem too acid for natural waters. It might be objected also that quantum yields fall off as Fe^{3+} builds up[4]. However, the hydrolysis of Fe^{3+}:

$$Fe^{3+} + 2H_2O \rightarrow FeOOH\downarrow + 3H^+ \qquad (9)$$

makes more protons than reaction (8) uses, suggesting possible autocatalysis in surface waters becoming more acid than the sea generally. Reaction (9) should also remove Fe^{3+} from the photoreaction zone by precipitation. (A fresh 0.01M solution of $FeCl_3$ has a *p*H of ~2.3 which after 2 days falls to about 1.8 by which time visible precipitation has set in [20].)

Getoff's experiments too are suggestive: organic molecules are formed by UV irradiation of CO_2-saturated solutions in the *p*H range 3.5–8.7 (ref. 6).

Even with the minimum model represented by equations (8) and (9) we can see that particular conditions of Precambrian seas, such as general *p*H, rates of mixing, and presence of buffers, could have been critical. And there are many other unknowns that could have greatly complicated the situation: traces of ions photoactive at longer wavelengths; a steady-state mix of organic molecules as possible scavengers[2,5] or photosensitisers[18]; or colloidal mineral crystallites allowing surface or solid-state photoreactions[21]. One conclusion is independent of very detailed knowledge: some photoredox processes would surely have been occurring in early Precambrian waters with, sometimes, the formation of volatile reduced species: if the atmosphere remained a sink for these (ultimately through loss of hydrogen to space) then so long as Fe^{2+} was there to prevent the escape from the seas of the corresponding oxidised species, inverse segregation would be a predictable outcome. Whether the banded iron formations are to be explained mainly or partially in such terms is another matter—but this non-biological light-driven mechanism seems qualitatively and quantitatively feasible.

I thank P. S. Braterman, R. J. Cross and R. Paterson for helpful discussions.

Stable isotopic compositions of early Archaean sulphate deposits of probable evaporitic and volcanogenic origins

SIGNIFICANT Archaean bedded sulphate deposits have been described only from the Pilbara Block (Western Australia)[1,2], the Barberton Mountainland (South Africa)[3–6] and southern India[7]. These are all barite deposits, but there is petrographic evidence suggesting replacement of original evaporitic gypsum in the North Pole (Pilbara) and Barberton deposits. This contrasts with the apparent volcanogenic deposition of barite in the relatively sulphide-rich Big Stubby prospect (Pilbara). This letter summarises the petrographic evidence, concentrating on recent data from North Pole, and reports stable isotopic results for barite and associated sulphides which provide corroborative evidence for the environments of formation of these deposits. Some implications concerning the early hydrosphere, atmosphere and biosphere are outlined.

The North Pole deposits[8,9] (21°07′ S, 119°28′ E) lie within a ~30-m thick fossiliferous[10] sequence consisting of laminated chert, silicified arenite and conglomerate, between slightly metamorphosed mafic and ultramafic volcanics of the Warrawoona Group[11]. Stratigraphic correlations suggest the North Pole sequence is of similar age to the ~3.45-Gyr-old[12] felsic volcanics of the Duffer Formation, and this is supported by a ~3.4-Gyr 'model age' for North Pole galena (J. Richards, personal communication). Various structures and textures suggest that the bedded barite and chert replaced an original evaporitic gypsum–carbonate sequence[8,9]. The barite beds are composed of bottom-nucleated crystal groups, 5–20 cm in length, radiating across bedding (Fig. 1). These strongly resemble 'cavoli' and grass-like evaporitive gypsum structures[13], and they contrast markedly with barite forms from both volcanic–exhalative and primary sedimentary deposits[14,15]. Some North Pole barite crystals have swallow-tail twins, and where it has been possible to measure interfacial angles of undeformed single

0028-0836/78/0276—0808$01.00

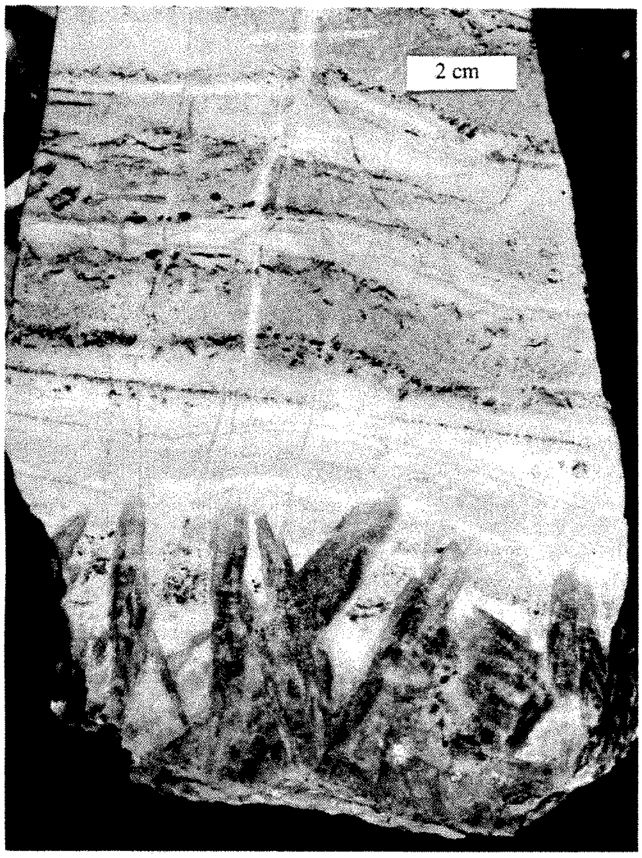

Fig. 1 Section of stratiform barite–chert horizon from North Pole showing large barite pseudomorphs after gypsum with overlying laminated chert (possibly stromatolitic). Universal stage measurements confirm that undeformed barite crystals have gypsum interfacial angles; mean angles for five measured crystals are $110 \Lambda 1\bar{1}0 = 68°12' \pm 0°50'$ and $\bar{1}10 \Lambda \bar{1}11 = 59°00' \pm 1°00'$. Most bedded barite crystals contain irregular domains in which barite is slightly misorientated with respect to adjacent domains and to the length of the crystal.

barite crystals, these have indicated crystal faces typical of gypsum but not recorded for barite (Fig. 1). Thus at least some barite is demonstrably pseudomorphing gypsum. Synsedimentary formation of the precursor gypsum is indicated by eroded crystals tops, and sediment drapes and fills between crystals. Intraformational conglomerates containing clasts of bedded barite attest to early lithification of precursor gypsum, if not early baritisation.

Clear, cryptocrystalline silica pseudomorphs after single or twinned gypsum crystals, commonly at high angles to bedding, occur in laminated, fine-grained, grey chert (Fig. 2). Ghost laminae within some of these silica pseudomorphs suggest a diagenetic origin for the crystals. Silica pseudomorphs after cubic minerals, and cubic voids, have also been observed in some chert beds, and a silicified hopper-shaped crystal occurs in one thin section. However, as is also the case in some younger evaporites, there is no evidence for the former presence of abundant halite at the North Pole.

That chert replaced carbonate sediments at North Pole is indicated by relic carbonate which is partially replaced by silica, stylolitised dolomite rhombs, and rhombic voids. Peritidal deposition of chert precursors is implied by laminated (possibly stromatolitic) bedding, graded- and cross-bedding, scour-and-fill structures, intraclast and edgewise conglomerates, ooid grainstones, ripple marks and probable desiccation features such as curved intraclasts and possible mud cracks. Thus depositional environments deduced independently from interlayered barite and chert are entirely consistent.

Minor bedded pyrite and sphalerite occur near the extremities of the North Pole barite and there are small galena pods within zones of recrystallised barite. Fluid inclusions in barite contain liquid CO_2, water and traces of H_2S.

The North Pole deposits contrast with the similarly ancient Big Stubby baritic–sulphide deposit in the Duffer Formation, some 40 km to the east. Published descriptions of Big Stubby[16,17] emphasise its geological, mineralogical and textural similarities to Kuroko-type volcanogenic deposits.

The barite near Barberton[3,4] (25°45′ S, 31°00′ E) is in the slightly metamorphosed, fossiliferous[18] Swaziland Supergroup. It is interbedded with carbonated felsic metavolcanics in a cherty sequence at the top of the ~3.45 Gyr (ref. 19) Onverwacht Group and in chert and siltstone of the overlying ~3.2 Gyr (refs 4, 19) Fig Tree Group. As at North Pole, much of the barite characteristically grew subperpendicular to bedding. It has been noted that it generally resembles evaporites in texture[4,10], and some small barite crystals in chert pseudomorph gypsum[20]. Thus, at least some Barberton barite probably formed in the same way as North Pole barite.

The isotopic results are shown in Fig. 3. δ^{18}O values for barite from North Pole and Barberton are both within the range +4.5–+10.1‰, except for a single Barberton value of +13.3‰. These are the first recorded δ^{18}O values for Archaean sulphates and they are, on average, less positive than for Recent evaporitic gypsum (~+9 ± 13‰)[21], possibly supporting the proposal that the Archaean hydrosphere was ^{16}O-enriched relative to younger waters (see ref. 22).

The δ^{34}S values for barite from widespread locations at the North Pole (average +3.6‰, s. d. 0.5‰) and the Barberton deposits (average +3.8‰, s. d. 0.4‰) are remarkably consistent. They are similar to the results obtained by Perry *et al.*[2,5] on small sample populations from each area and less variable than the results of Vinogradov *et al.*[6] for all barite morphologies in the Fig Tree Series (average +5.0‰, s. d. 1.5‰). Individual post-Archaean evaporitic sulphate deposits also have uniform sulphur isotope composition, but their δ^{34}S values are characteristically $\geq +10$‰ (ref. 23); apparently they commonly reflect the isotopic composition of contemporaneous seawater SO_4^{2-}, with δ^{34}S values of sulphate minerals being a maximum of 2‰ heaver than SO_4^{2-} in the parent brine[23]. The purportedly volcanogenic barite at Big Stubby has markedly higher δ^{34}S values than barite from North Pole and Barberton, and is evidently not reflecting the $\delta^{34}S_{SO_4^{2-}}$ values in the contemporaneous hydrosphere.

The δ^{34}S values for sulphides from North Pole and from sedimentary rocks penecontemporaneous with the Barberton

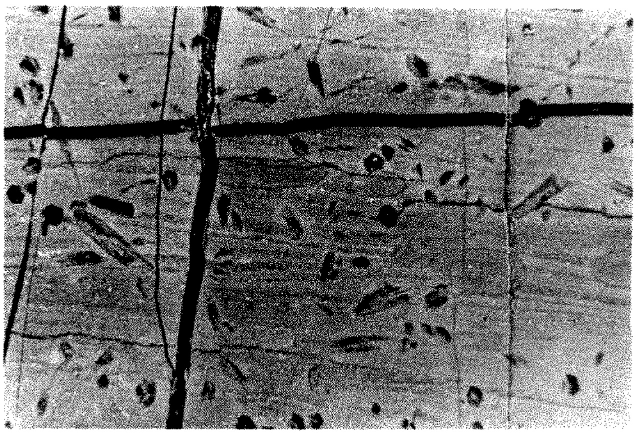

Fig. 2 Photomicrograph of laminated chert (light grey) from North Pole containing well formed silica pseudomorphs after gypsum (medium grey). Pseudomorphs show characteristic interfacial angles for gypsum. Mean angles for 12 crystals are $110 \Lambda 1\bar{1}0 = 68°48' \pm 1°18'$, $110 \Lambda 010 = 56°00' \pm 0°33'$ and $\bar{1}10 \Lambda \bar{1}11 = 59°00' \pm 0°55'$. Field of view 3.5 × 2.4 cm.

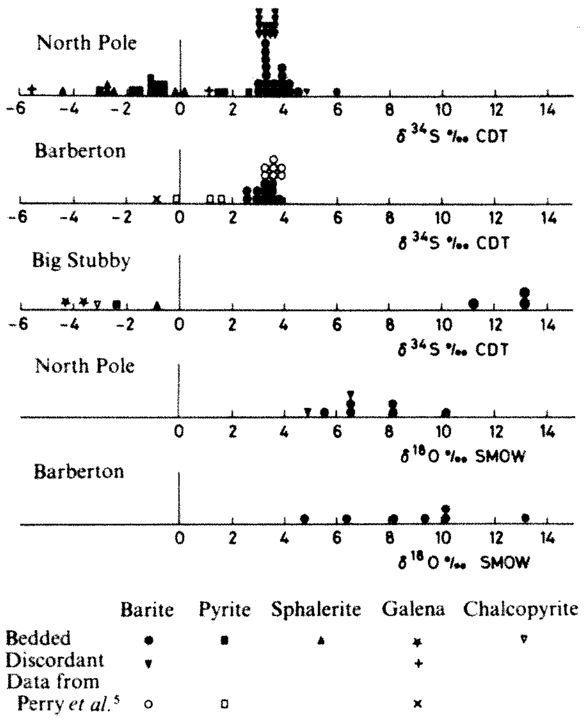

Fig. 3 Stable isotope data. The results from North Pole and Barberton are similar, and they corroborate petrographic evidence for sedimentary–evaporative deposition. Discordant barite at North Pole formed by remobilisation of bedded barite as a result of tectonic doming[8,9]. The contrasting $\delta^{34}S$ pattern at Big Stubby supports textural, mineralogical and geological evidence[16] for its volcanogenic origin. Weighted mean $\delta^{34}S_{\Sigma S}$ values indicate sulphur of juvenile derivation in each case.

barite deposits average −0.9‰ (s. d. 1.5‰), and Big Stubby sulphides have a slightly more negative average $\delta^{34}S$ value. These are similar to values in sulphate-free, Archaean volcanogenic sulphide deposits[24], but differ from younger volcanogenic sulphide deposits which generally do not have $\delta^{34}S$ values close to 0‰ (ref. 25).

The weighted mean $\delta^{34}S$ values for the essentially monomineralic barite deposits at North Pole and Barberton, and for the sulphide-rich Big Stubby deposit, are similar. In each case the $\delta^{34}S_{\Sigma S}$ in the depositional waters must have been close to 0‰, implying sulphur of juvenile origin. The $\Delta^{34}S$ (barite–sulphide) values of $\sim +15‰$ at Big Stubby are comparable with those in the younger volcano-exhalative deposits[25]. In contrast, the much smaller $\Delta^{34}S$ (barite–sulphide) values at North Pole and Barberton (average $< +5‰$) show no evidence of approach to isotopic equilibrium at hydrothermal or surface temperatures[26]. Ascending juvenile fluids could not have contained $SO_4^{2-} \gg H_2S$, HS^- because sub-surface reactions would have favoured the reduced species. Therefore, the isotopic results indicate that sulphates at North Pole and Barberton could not have been deposited directly from exhalations. These sulphates must have formed largely as a consequence of surficial oxidation of reduced sulphur which was introduced into the hydrosphere by exhalative activity. Oxidation could have been effected by blue-green algae or sulphur bacteria (microfossils are present[10,18]), although the importance of oxygen production by photolysis of water vapour[27] cannot be ruled out. Oxidation of reduced sulphur is a rapid non-equilibrium process which does not lead to significant isotopic fractionation.

The clear evidence for precursor gypsum at North Pole and Barberton argues against deposition of major proportions of primary barite, as proposed by Perry *et al*[5]. The only model satisfying both isotopic and petrographic constraints is one in which the high concentrations of isotopically homogeneous SO_4^{2-} required for sedimentary gypsum deposition built up in restricted basins as a result of evaporation and recharge from external sources.

Baritisation of the gypsiferous sediments was presumably accompanied by precipitation of additional barite as the Ba^{2+}-bearing fluids reacted with residual SO_4^{2-} in basin and interstitial waters. Barite produced by these processes would have $\delta^{34}S$ values similar to precursor gypsum. The origin of the Ba^{2+} is uncertain, but it may have been derived from exhalations related to felsic volcanism (Duffer Formation), or from diagenetic-burial metamorphic reactions.

The minor amounts of sulphides with the barite probably formed from exhalative sulphur which was not oxidised in the depositional basins: the presence of H_2S in fluid inclusions may be significant in this respect. Had they formed by bacterial reduction in SO_4^{2-}-rich evaporative environments, the sulphides would have had wide ranges of $\delta^{34}S$ values, most being highly negative relative to $\delta^{34}S$ values of sulphate. Except for the ~2.7-Gyr BP Michipicoten iron formation[28], available isotope data for Archaean sulphide mineralisation have not produced evidence for bacterial SO_4^{2-} reduction[24].

The occurrence of gypsum and barite does not require an oxygenated atmosphere in the early Archaean; this would only have existed if the oxygen 'sinks' (such as, H_2S, CH_4, Fe^{2+}) in the hydrosphere and atmosphere were saturated. The sulphate-free volcanogenic sulphides in other, apparently deeper-water Archaean sequences provide evidence that the hydrosphere was not everywhere oxidised. They suggest either the presence of reduced waters under a surficial oxidised zone[29,30] or the existence of separate seas with different degrees of oxidation.

The Archaean scenario envisaged here is one in which: (1) juvenile, sulphurous exhalations (H_2S, $HS^- \gg SO_4^{2-}$) were being added to the hydrosphere and atmosphere; (2) there was local oxidation of reduced sulphur by microbes (or photolysis), but oxygen was not necessarily a stable component of the atmosphere; (3) bedded sulphate deposits formed in shallow-water, evaporitic environments; (4) relatively small, baritic sulphide deposits precipitated directly as a result of volcano–exhalative activity; (5) sulphate-free, exhalative sulphide mineralisation formed in deeper water and/or lower f_{O_2} environments; and (6) bacterial SO_4^{2-} reduction was absent, or not of widespread significance.

Metal-enriched sediments from the TAG Hydrothermal Field

A SERIES of sediment samples from the TAG Hydrothermal Field[1] have been collected and analysed for transition metals, and for uranium and thorium isotopes. We show here that metal enrichment of sediment samples is ubiquitous, but geographically variable. Non-detrital metal accumulation rates in one core are Fe and Mn 15.0 and 0.7 mg cm^{-2} 10^{-3} yr; and Ni, 180; Co, 93; Cu, 134; and Cr, 148 μg cm^{-2} 10^{-3}yr. The hydrothermal field is located on the eastern wall of the Mid-Atlantic Ridge Rift Valley at 26°N and covers ~100 km^2. It is characterised by extensive deposits of thick, rapidly growing MnO_2 (ref. 2) and by a magnetic low in the axial anomaly[1].

Figure 1 shows that the sediment thickness is quite variable even over a small area of the valley floor. Core 4A (132 cm of sediment) and core 4G (15 cm of sediment) both terminated with basaltic glass, and a core from site 4C recovered glass only, with no overlying sediment. A study of bottom photographs of this section of the median valley[3] shows ripple marked sand and other evidence of the strong bottom currents responsible for sweeping sediment off some portions of the valley floor into sediment ponds of uneven distribution.

Three types of sediment were collected during the 1973 cruise of the Discoverer: (1) samples 4A, 4B and 4H are cores of ponded carbonate ooze sediment in the median valley; (2) $CaCO_3$-rich clay was dredged from the top of a small terrace (dredge site 2A); and (3) sediment interstitial to and covering boulders in the talus was recovered from dredge sites 2A and 3A. This material was less than 5% carbonate and consisted largely of altered basalt debris.

Chemical analyses were made on the sediment samples by atomic absorption spectrophotometry. The results are given in Table 1 along with metal-to-aluminium ratios for average North Atlantic pelagic clay[4–11] for comparison. The metal-to-aluminium ratios for the average North Atlantic clay is considered to be characteristic of the detrital component of the sediment on which hydrothermal additions are superimposed. Note that none of the samples analysed are very highly enriched in metals compared to the average North Atlantic pelagic clay values. The highest Mn/Al ratios were observed in one of the samples from Dredge Site 2A and the $CaCO_3$-rich terrace sediment, but the maximum enrichment of Mn relative to the average North Atlantic clay Mn/Al value was only about 7, in contrast to enrichments of 100 or higher found on the East Pacific Rise[12]. The presence of a large deposit of Mn oxide found in the nearby hydrothermal field[2] clearly suggests a significant flux of Mn into seawater in this general vicinity. Scott *et al.*[2] have measured the accumulation rate of the Mn oxide deposit and found it to be 100–200 mm Myr^{-1} or 2 orders of magnitude faster than typical deep sea ferromanganese deposits. It is surprising that so little of the Mn is deposited in the adjacent sediments.

Iron-to-aluminium ratios in the TAG sediments showed even less pronounced enrichment than the Mn/Al ratios. The average Fe/Al ratio for all samples analysed is 0.89 in comparison with the average North Atlantic pelagic clay ratio of 0.56 (Table 1). Most of the Fe in these sediments is detrital in origin. Betzer *et al.*[13] have found much higher Fe/Al and Mn/Al ratios on a total sample basis for the suspended matter sampled from near bottom water over the ridge crest than for similar particles sampled to either side of the ridge crest. Some of the Fe and Mn in the hydrothermal fluids are probably precipitating in the water column after they enter the ocean. They are diluted in the underlying sediment by biogenic and detrital material being deposited at the same site, and are undoubtedly also being wafted away from the area by currents. The nearly total absence of Fe in the massive hydrothermal MnO_2 deposit[2] (Fig. 1) suggests that the Fe may be removed as pyrite[14] or other minerals before the hydrothermal fluids debouch onto the sea floor from that vent. The variability in metal enrichments between the massive MnO_2 deposits and the metal enriched sediments indicates variability in the chemistry of the hydrothermal fluids in both space and time.

The metal-to-aluminium ratios of samples from core 4A show that the core is somewhat enriched throughout its length in Fe, Mn, Ni, Cu, Co and Cr with respect to average North Atlantic pelagic clay (Table 1). The Mn content of the 30–32 cm interval falls below the average pelagic clay value, but this is probably the result of dilution by basaltic glass fragments at that depth that were not removed from the sediment before analysis. The Co and Cu values are very strongly correlated with Mn content, showing correlation coefficients of +0.95 and +0.97 respectively. These metals may be concentrated from seawater by precipitating hydrothermal Mn, or they may also be contributed by the hydrothermal solutions themselves. Nickel and Cr in the core are not correlated with Fe, nor with Mn, nor with each other. The factors controlling their distribution cannot be determined without further investigation.

Metal enrichment studies of ridge crest sediments based only on metal-to-aluminium ratios omit a very important parameter—time. The ratios observed in the sediment reflect not only the intensity of the metal source, but also all of the other processes operating to dilute the metals being added by ridge crest processes. An estimate of the rate at which the metals are added compared to analogous rates for non-metalliferous sediments avoids this problem.

* The accumulation rate for the non-detrital fraction of Core 4A was calculated by subtracting a detrital metal component based on the detrital metal-to-aluminium ratio (average North Atlantic pelagic clay) and the accumulation rate of aluminium in Core 4A.

The sedimentation rate of core 4A was measured by means of the ^{230}Th excess method (Table 2). The rate at which this sediment is accumulating is ~1.8 cm kyr^{-1}. This rate is consistent with Mid-Atlantic Ridge sedimentation rates measured by other workers[15–17]. Note in Table 2 that ^{234}U/^{238}U activity ratios >1 exist over the whole length of the core, in some cases beyond corrections for 3 s.d. of counting statistics. Post depositional hydrothermal additions of uranium to ridge crest sediments have been previously noted[18–21]. The same interpretation seems reasonable for these data. Addition of ^{234}U-rich uranium would distort the accumulation rate towards a lower value.

Metal accumulation rates have been calculated for core 4A on the basis of average metal concentrations and porosity (Table 1) and the measured sediment accumulation rate of 1.8 cm kyr^{-1} and are listed in Table 3. The Al content of marine sediments is commonly used as an index of the detrital component. We calculated the metal accumulation rates for the detrital component of core 4A using the average Al content of 4A (Table 1), the sediment accumulation rate of 4A, and the metal-to-aluminum ratios for average North Atlantic pelagic clay (Table 1). These values were subtracted from the whole sediment values, yielding the non-detrital accumulation rates listed in Table 3. These rates include only material from non-detrital sources.

The non-detrital metal accumulation rates (Table 3) show that Fe, Mn and the trace metals are being added to sediment in the TAG area at rates that are well above the background values for the North Atlantic Ocean. Iron and manganese accumulation rates on the East Pacific Rise[22–24] are much greater than at this site on the Mid-Atlantic Ridge. However, the Ni, Co, Cu, and Cr accumulation rates are conspicuously high in comparison with East Pacific Rise data. The differences observed in sediments from the two active ridge areas may be related to water circulation differences in the hydrothermal systems of fast and slow spreading ridges[25]. Note also that metal enrichment in TAG area sediments may be higher than average for hydrothermal areas on the Mid-Atlantic Ridge. Sediments from the FAMOUS area at 37° N were found to be accumulating metals at much slower rates than those reported here[18].

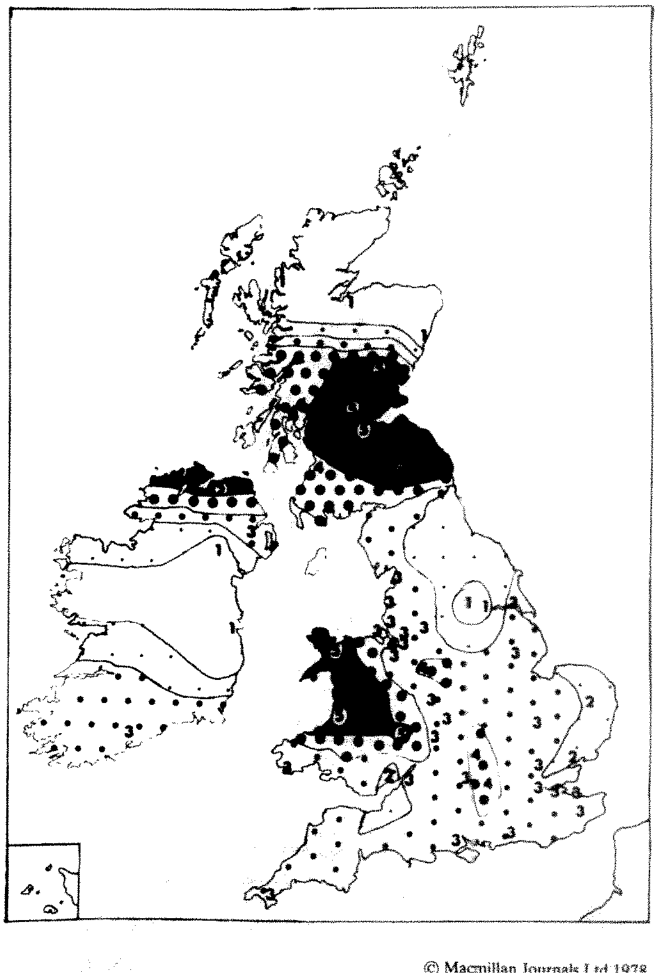
A survey of ozone levels in the British Isles using indicator plants

THE occurrence of elevated levels of photochemically-produced ozone in the British Isles has been reported by several workers[1–4]. Such elevated concentrations are not restricted to urban areas, but can occur far from sources of pollution[1,3,5,6]. Most of the measurements of ozone have been made in South-east England; there has been no systematic attempt to study its distribution over the whole country. We report here results of a nationwide survey of ozone concentrations, using the appearance of visible injury on the leaves of a sensitive plant species as an indicator of the presence of the pollutant.

Fig. 1 The distribution of leaf injury, derived by computer interpolation from the mean values of weekly leaf injury index at 53 sites for the period 13 June–5 September 1977. Five classes (denoted by increasing degrees of shading) are distinguished, covering the following ranges of values: 1, 0·01–0.54%; 2, 0.54–1.06%; 3, 1.06–1.59%; 4, 1.59–2.11%; 5, 2.11–2.64%.



0028-0836/78/0276—0813$01.00

The plant used in this study was *Nicotiana tabacum* cv. Bel-W3. This cultivar has a threshold for the appearance of visible leaf injury at 0.04–0.05 p.p.m. ozone (the maximum concentration in which ozone normally occurs naturally), and the extent of leaf injury has been shown to be related to the amount of ozone to which the plant has been exposed[7–9]. The plants normally were grown in heated glasshouses in standard composts and then 'hardened off' for one week in an unheated glasshouse, before being placed in the field. Their age at this time was 8 weeks. The plants remained in the field for 4 weeks, and were then replaced by a fresh batch of 8-week-old plants. Six replicate plants were exposed at each site. The exposure sites chosen were open, and at a suitable distance from any local source of other pollutants. Wind protection was provided.

The percentage of the area of each leaf covered by typical ozone-induced lesions was estimated visually at each site at weekly intervals. From these data, the change in the mean percentage of leaf area injured (which we term the leaf injury index) was calculated for each week. Photographs and leaf samples were provided to help in identification of ozone damage, while at many sites, plants of an ozone-resistant cultivar, Bel-B, which showed little or no ozone damage, were placed alongside the test plants. Leaves were sent to us to confirm the identification of damage, and to determine the accuracy of damage assessment by comparing the visual estimates with objective estimates obtained using a grid placed over the leaf.

Figure 1 shows the distribution of leaf injury. Because of an absence of data, little importance can be attached to the interpolated values in certain areas (for example, the sharp changes in injury around Berwick). However, it is encouraging that values for neighbouring sites were usually in agreement. Ozone is produced by a series of photochemical reactions from nitrogen oxides and reactive hydrocarbons. The major source of these pollutants is motor vehicle exhausts, and thus high concentrations of ozone, and large amounts of leaf injury, might be expected to occur in areas of high population density. Yet in 1977, the amount of leaf injury in certain urban areas was relatively low, while it was high in some rural areas, such as North Wales. Only in northern Scotland was no leaf damage found.

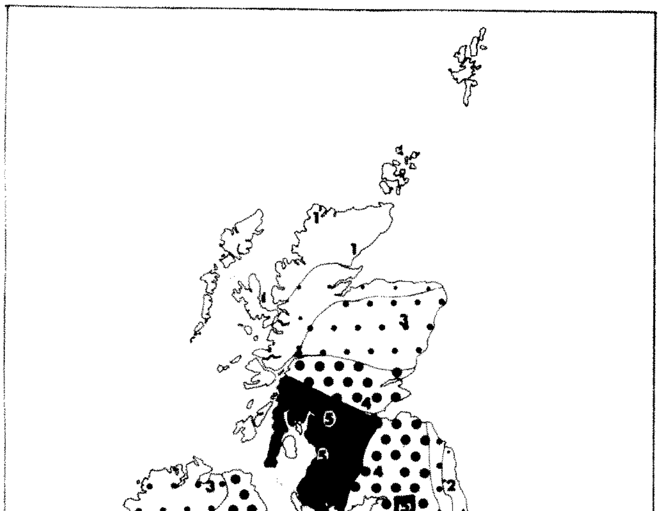


Fig. 2 The distribution of mean values of weekly sunshine hours for the period 13 June–5 September 1977, derived by computer interpolation from Meteorological Office records. The five classes distinguished cover the following ranges of values: 1, 28.9–33.2 h; 2, 33.2–37.5 h; 3, 37.5–41.9 h; 4, 41.9–46.2 h; 5, 46.2–50.5 h.

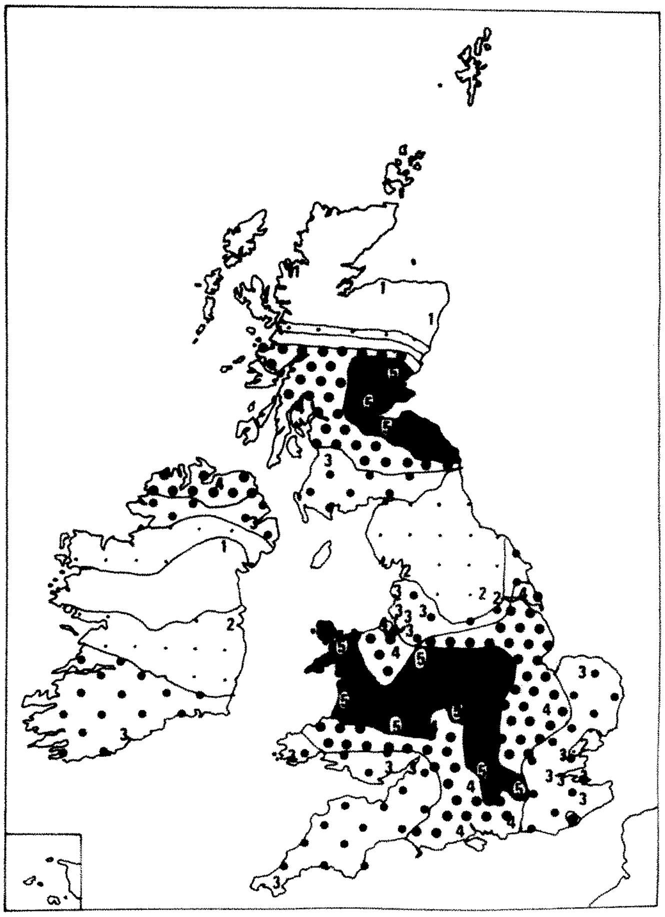

Fig. 3 The distribution of values of k, calculated as described in the text. The five classes cover the following ranges of values: 1, 0.0–0.03; 2, 0.03–0.07; 3, 0.07–0.10; 4, 0.10–0.14; 5, 0.14–0.17.

The levels of sunshine in the summer of 1977 were greatest in the north and west of the country (Fig. 2). As the presence of sunlight is required to drive the reactions leading to ozone formation, its concentrations tend to be high when sunshine levels are high[2,4,5]. Comparing Figs 1 and 2, it can be seen that the highest amounts of leaf injury tended to occur in those areas receiving the greatest amount of sunshine. We found a significant correlation ($r = 0.554$, $P < 0.001$) between the values of mean weekly leaf injury index (LII) and mean weekly (SH) or daily (S) sunshine hours. This relationship could be expressed by the equation $\mathrm{LII} = k\mathrm{SH}$ where $\mathrm{SH} = \Sigma\ (\mathrm{S} - 6.0)$. The value of 6.0 h gives an estimate of the amount of sunshine needed, on average, to produce sufficient ozone to cause leaf injury. The value of k for the fitted relationship was 0.113% h^{-1}. Values of k can also be calculated for individual sites. These values can be used to predict the distribution of leaf injury if the amount of sunshine was uniform over the whole country (Fig. 3). This map shows four bands of alternating high and low leaf injury, lying roughly SW–NE across the country, corresponding to regions of high or low degrees of urbanisation. Meteorological Office records show southwesterly and northeasterly to be the predominant wind directions on sunny days in 1977.

The maps shown here are intended to illustrate general patterns—we do not attach great importance to the precise details of Figs 1 and 3 and concede that the model we have used is a very simple one. It is known that meteorological factors other than sunshine affect the magnitude and distribution of ozone concentrations[1,3–6]. We also concede that the results of one summer must be interpreted with caution; no two summers are the same, especially in Britain. The summer of 1977 was unusually dull, and ozone concentrations were relatively low; stable anticyclonic conditions which are typically associated with very high ozone concentrations[1,3,5–6] were very rare. However, our results do show that, given favourable weather, ozone concentrations sufficient to damage our test plants can occur anywhere in the British Isles, with the possible exception of northern Scotland. Furthermore it would be expected that both the extent and the concentration of ozone would be lower under the climatic conditions of 1977 than in most years.

We thank all the collaborators who provided these data, and acknowledge the financial support of the NERC.

^{13}C Content of human collagen as a measure of prehistoric diet in woodland North America

PLANTS with the C_4 dicarboxylic acid pathway of photosynthesis have markedly higher $^{13}C/^{12}C$ ratios than plants with the C_3 or Calvin pathway[1–4]. Cumulative assessments of relative ^{13}C concentration ($\delta^{13}C$) values for C_3 plant foliage yield an average of −26.5‰, relative to the PDB standard whereas C_4 plants average −12.5‰ (ref. 5). These differences in carbon isotope ratios are passed along the food chain to animals and man, so that the nature of the plant food base can be determined through measurements on different body tissues of the consumers. In this study, the time of introduction of maize, a C_4 plant, to the prehistoric inhabitants of several regions in woodland North America, almost exclusively a C_3 plant regime, was determined through isotopic measurements on human bone collagen. The subsequent elevation of maize to the level of a diet staple is also documented.

When plant foods are consumed by animals and man, the $^{13}C/^{12}C$ ratios of the plants are further fractionated in the formation of different body tissues[6,7]. In African browsing ungulates, with diets made up almost exclusively of C_3 foliage, the average $\delta^{13}C$ measurement (relative to PDB) on bone collagen is −21.2‰ (ref. 8). The collagen is apparently enriched by 5.3‰ relative to the food base, but a possible small C_4 plant component in the diet may have added slightly to this enrichment value. Measurements on other body tissues of the same animals yield average $\delta^{13}C$ readings of −21.8‰ for hide and hair, −23.5‰ for flesh and −28.9‰ for fat. It can be calculated from these values that hunter–gatherers who lived in a C_3 environment such as the North American woodlands and who had diets estimated at 20% animal and 80% plant foods had a food web with an average $\delta^{13}C$ value closely approximating that of C_3 plants. The observed addition to their diet of freshwater fish and molluscs would not have changed the situation materially as these organisms also resemble C_3 plants in ^{13}C content. The addition of C_4 plants to the diet will have a profound effect, of course, and the percentage of C_4 plants in the diet should be measurable in the body tissues. This is also true for marine foods in the diet, as marine fauna have an average $\delta^{13}C$ value of about −15‰, with values becoming more negative with decreasing ocean temperatures. These predictions can be seen to hold for a sample of 38 pre-Iron Age Europeans, with a food web based on C_3 plants and a possible marine faunal component, and an average $\delta^{13}C$ value in their bone collagen of −20.4 ± 1.4‰ (refs 9, 10).

Turpin Site average	(10)	(−11.8 ± 1.3)	(69)

To use isotopic measurements as a means of dietary assessment in humans it is necessary to eliminate seasonal factors. Collagen is useful in this respect as its carbon turnover rate is about 10 yr; it is also preserved in archaeological sites. To use collagen, it is also necessary to know accurately the shift in isotopic composition between the plant food base and collagen. We determined this value by measuring the isotopic ratios of collagen from 31 North American skeletons, for an average $\delta^{13}C$ value (relative to PDB) of −21.4 ± 0.78‰ (Table 1). These skeletons derive from hunter–gatherer cultures of Ohio, Illinois, and West Virginia, with archaeologically documented diets of C_3 plants, terrestrial animals and freshwater fish and molluscs[11–16]. A few C_4 species of *Amaranthus*, *Panicum* and *Chenopodia* may have been included in this diet, but apparently in insufficient quantity to have a measurable effect. The consistency of the readings and the wealth of archaeological information on diet make this set of readings the most useful to date for calculating the shift in isotopic composition between the base of the food web ($\delta^{13}C$ = −26.5‰) and human bone collagen ($\delta^{13}C$ = −21.4‰). The collagen enrichment (+5.1‰) was used in the rest of our study to calculate relative contributions of C_3 and C_4 plants in human diets.

C_4 plants include several cultigens of economic importance, for example, sugar cane, maize and sorghum[17]. Their contribution to a diet which is otherwise based on C_3 plants can be

0028–0836/78/0276—0815$01 00

calculated from isotopic measurements on bone collagen. A diet consisting totally of C_4 plants should yield bone collagen with $\delta^{13}C = -12.6 + 5.1$‰ or -7.5‰. Isotopic measurements between -7.5‰ and -21.4‰ reflect a mixture of C_3 and C_4 diet components. Variation between individuals could change the calculated relative percentage by ±6%, multiple measurements for a site are, therefore, preferred.

In a pilot study of archaeological skeletons from New York[18], a shift away from the C_3-based $\delta^{13}C$ average was observed to accompany the introduction of maize cultivation to the area. This effect is confirmed by measurements on 21 skeletons from sites in Ohio and Illinois (Table 1) where the evidence for maize cultivation is clear. It should be noted that the introduction of maize to this region was also accompanied by the exploitation of imported wild C_4 plants (such as amaranth), which cannot be isotopically distinguished from maize. The contribution of these plants is considered to be minor.

The introduction of maize cultivation in the lower Illinois Valley can be assessed from the isotopic readings. There is no measurable C_4 component in the Archaic (Koster), Middle Woodland (Gibson Mounds) or even the beginning of the Late Woodland period (Koster Mound Group). Occasional maize remains occur in the archaeological record from the Middle Woodland onwards, but in quantities small enough to suggest a trade origin. Exotic artefacts from a wide trade network occur in the same deposits. These sporadic injections of maize in the diet were insufficient to register in the long-term isotopic average of bone collagen. Only in the end of the Late Woodland period (Ledders Mounds, ~AD 1000), when fully agricultural Mississipian cultures were already present in other parts of Illinois, can clear evidence for maize cultivation be seen in a C_4 diet component of ~24%. Thereafter, the importance of the cultigen increased rapidly to ~50% by about AD 1200, among populations represented at Schild Cemetry Knoll B (Mississipian) and Noble–Wieting (early Upper Mississipian).

In Ohio, the measurements now available illustrate the wide gap in isotopic values between hunter–gatherers (Du Pont) and fully agricultural, Upper Mississipian peoples (Turpin). The latter show an average C_4 diet component of ~69%. Separated by sex, the averages are ~64% for six females and ~75% for four males. These results suggest a higher C_3 plant intake among women, perhaps in the course of gathering wild plant foods, and are being checked using a larger population. Further measurements are also underway to pinpoint the 'threshold' of maize cultivation in Ohio, Illinois and other Woodland areas.

A C4 plant from the Pliocene

THE Kranz syndrome[1,2] is a group of physiological and anatomical features occurring in certain angiosperms; the grasses in particular show increasing efficiency in CO_2 assimilation. Recent research[3,4] suggests an origin of the syndrome in South America and its subsequent dominance in other continents. The Kranz syndrome occurs in all plants fixing CO_2 by phosphoenolpyruvate carboxylase in the mesophyll and subsequent production of Calvin–Benson cycle intermediates in the bundle sheath[5]. The physiological processes in C4 plants are closely related to their specialised leaf anatomy known as Kranz anatomy[6] by which they are distinguished from C3 plants. It is suggested that ancestral non-Kranz C3 grasses originated during the Cretaceous period[4]. We report here fossil evidence indicating that C4 plants occurred at least during the late Tertiary period.

Petrified grasses (Fig. 1*a*) were collected from two localities (Last Chance Canyon and Sperry Hills area) in the Pliocene Ricardo Formation of California. Several specimens from these localities show similarities in their gross morphological features. The culm, present in the majority of specimens, is notched at the distal end and contains a relatively small amount of mechanical tissue. Conversely, at the base of the round culm there are hypodermal bundles imbedded in abundant sclerenchyma. Sheathing leaf bases are imbricate and wrap around the central culm (Fig. 1*d*). Wherever a culm is absent the young leaf at the centre is convoluted. Leaves on specimens from Sperry Wash show marked ridges and furrows. These furrows are probably stomatal locations. Thus, these specimens show Kranz anatomy typical of C4 plants. In addition to a prominent bundle sheath, C4 species are characterised by a low interveinal distance (less than four mesophyll cells between veins) and the presence of radiating parenchyma in the mesophyll[7]. Mesophyll cells in these fossil leaves are occasionally radiating parenchyma. In the absence of radiating parenchyma up to four mesophyll cells are present between the veins (Fig. 1*e*). Certain specimens from the Sperry Hills locality have structural features usually associated with C4 photosynthesis.

Fossil material was subjected to hydrofluoric acid digestion to remove the silicate material. The remainder (mainly cuticle) was then combusted at 800 °C and the CO_2 collected for isotope analysis. The results are presented as $\delta^{13}C‰ = [(R\ \text{sample} - R\ \text{standard})/R\ \text{standard}] \times 1{,}000$, where R = the mass 45 to mass 44 ratio of sample or standard. The standard was PDB (Chicago). C4 plants have Kranz anatomy and $\delta^{13}C$ values of -9 to -16‰ while C3 plants have $\delta^{13}C$ values of -23 to -36‰ and do not exhibit Kranz anatomy. Fossils exhibiting the Kranz anatomy gave a $\delta^{13}C$ value of -13.7‰, indicative of C4 photosynthesis, while non-Kranz fossils gave a value of -24.6‰, similar to C3 plants.

The existence of the C4 photosynthetic pathway is supported by the presence in Ricardo Formation of petrified roots resembling extant panicoid plants. These fossil roots have a central stele surrounded by an aerenchymatous cortex (Fig. 1*c*). Air chambers in the cortex are reticulate as found in *Paspalum commersonii* Lamk. and *P. ciliatifolium* Michx; species of *Paspalum* are known to exhibit C4 photosynthetic pathways[8]. Previous authors have presented evidence for a fruit resembling *Triticum* in the Eocene Deccan Intertrappean beds of India[9] and plants resembling the tribes Stipeae and Paniceae[10] in the Miocene–Pliocene beds in North America.

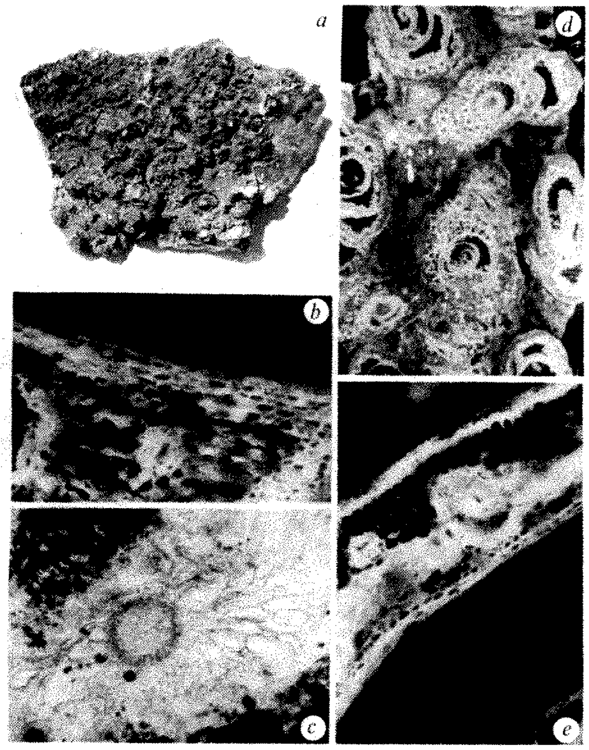

Fig. 1 Petrified grass plants from the Pliocene Ricardo Formation in California. *a*, Distribution of the petrified grass plants in the chert, ×½; *b*, radiating parenchymatous cells of the mesophyll tissue occur between veins, ×100; *c*, petrified grass roots with aerenchymatous cortex resembling the extant genus *Paspalum*, ×105; *d*, sheathing leaf bases wrap around a central culm. In the absence of the culm, leaves at the centre are convolute, ×17; *e*, lamina of the leaf in cross section. Between the veins are about 4 mesophyll cells, ×29.

The presence of petrified grass plants in the Ricardo Formation corroborates the reports on grazing animals in these Pliocene beds[11,12]. Palaeoclimatic determinations are indicative of a plains habitat during Ricardo times[13] with steep slopes bordering plains and relatively less aridity than at present. Such conditions influenced the growth and propagation of grasses as seen in the Chapparal of Mediterranean climates[13].

We thank Mr Jim Stichka and K. D. Kehrberg for their help in collecting material.

Canine tooth size in female primates

AMONG mammals, weapons such as canine teeth or antlers are often more pronounced in males than in females[1–5]. Two reasons are normally proposed for such sexual dimorphism. First, there is more competition among males than among females for access to mates and, in consequence, there is enhanced selection for fighting ability[6–9]. Second, such weapons are important organs of defence for the male, who often assumes the role of defending his mates and offspring from predators[9,10]. In this paper, we discuss a third factor that is involved: selection acting to influence the size of weapons in females.

In primates, sexual dimorphism in canine size seems to be influenced by both inter-male competition for mates and defence against predators by males[9]. Males of polygynous species, where competition for access to mates is intense, have larger canines (relative to their body size and the canine size of female conspecifics) than males of monogamous species. Also, males of terrestrial species, where anti-predator defence is probably important, have larger canines than those of arboreal species. Much of the variance in canine sexual dimorphism remains unexplained, however, probably partly because additional selective pressures affect female canine size. In particular, selection for enhanced female fighting ability (and thus relatively enlarged female canine size) might be expected in monogamous species, where females participate more frequently in territorial encounters and heterosexual aggression than females of polygynous species[11,12]. Of the primates that live in larger groups, female aggression may be more frequent in those species that live in multi-male groups than those living in single-male (harem) groups, for two reasons. First, there is growing evidence[13,14] that female primates may suffer considerable feeding interference from males and it is likely that this will be more intense when there are more males per female in the social unit. (This situation is paralleled in some ungulate species, where females have developed horns or antlers apparently to assist them in feeding competition with males[15–17].) Second, although aggressive inter-female competition over resources may occur in either type of group, females in harems are usually more closely related, and so less competitive with each other, than females living in multi-male groups[7,18,19].

On these grounds, we predicted that females of monogamous species and those living in multi-male groups should have larger canines relative to their body weight than those living in harem groups. Since there is evidence that terrestrial male primates have relatively larger canines than arboreal species[9], we

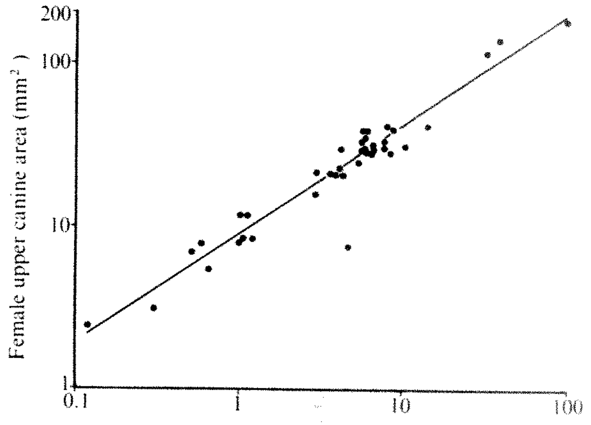

Fig. 1 Female upper canine size regressed on body weight. Both axes are scaled logarithmically.

examined this relationship in arboreal and terrestrial species separately. Similarly, to allow for any possible effect of diet on female canine size, we have also examined the relationship within folivorous and frugivorous species.

Our measure of canine size is the basal area of the tooth (the product of maximum mesiodistal and maximum buccolingual lengths), which is closely related to canine length ($r = 0.89$, $n = 34$, (ref. 9)). All the dental measurements were extracted from Swindler[20] and are presented elsewhere[9]. Data on body weight, diet and breeding systems are taken from Clutton-Brock and Harvey[21,22]. Female canine size is closely related to body weight (Fig. 1). To remove this effect, we calculated the regression of the natural logarithm of female canine size on the regression of the natural logarithm of non-pregnant body weight for females of 39 species, and measured the deviation in female canine size for each species from the value predicted from female body weight. Our measure of Relative Female Canine Size (RFCS) was the observed canine size, divided by the expected.

As predicted, female primates of harem-forming species have, on average, smaller canines for their body size than do females of other species (Table 1). When the effects of either diet or terrestriality are removed, the differences due to breeding system remain statistically significant for both upper and lower canines (Table 2). There are differences in RFCS between folivorous and frugivorous species, and between arboreal and terrestrial species (Table 1), but when the effect of breeding system is removed, none of these differences is statistically significant (Table 2). In all cases the interaction components are not significant.

Although we have used data from various sources and may therefore have introduced some error[21], our results give statistical support to the hypothesis that selective pressures for female fighting ability are stronger in monogamous species and those living in multi-male groups than in harem-forming primates.

Two possible artefacts may have affected our results. First, if the group sizes of harem-forming species were significantly smaller than those of other species, then this alone might account for the differences between them because intraspecific competition in the former might be relatively reduced by the lower number of animals present. In fact, harem-forming species do not live in smaller breeding or feeding groups than the other primates in our sample[22]. The second possibility is that our results are the product of differences between catarrhine and other primates; catarrhines are noted for their well-developed canines[1,23,24]. It is unlikely, however, that this could explain the relationship between breeding system and RFCS, since all the species in our sample of harem-forming species were catarrhines.

Table 2 Statistical analysis of relative female canine sizes according to breeding system, diet and degree of terrestriality

The distance and nature of the light-trap response of moths

LIGHT TRAPS of various forms have been used to collect and study moths for well over 100 yr, but surprisingly little is known about how they attract moths. There has been some evaluation of the factors influencing the size of light trap catches[1-5] and of the mechanics of the terminal phase of the moth's approach to a light[6], but virtually nothing is understood about the light-trap response itself. Such an understanding is perhaps unnecessary when light traps are used solely to collect specimens, but becomes crucial as soon as they are used for quantitative sampling or survey work[7]. Of particular importance to the interpretation of such work is a knowledge of the distance from which

0028-0836/78/0276—0818$01.00

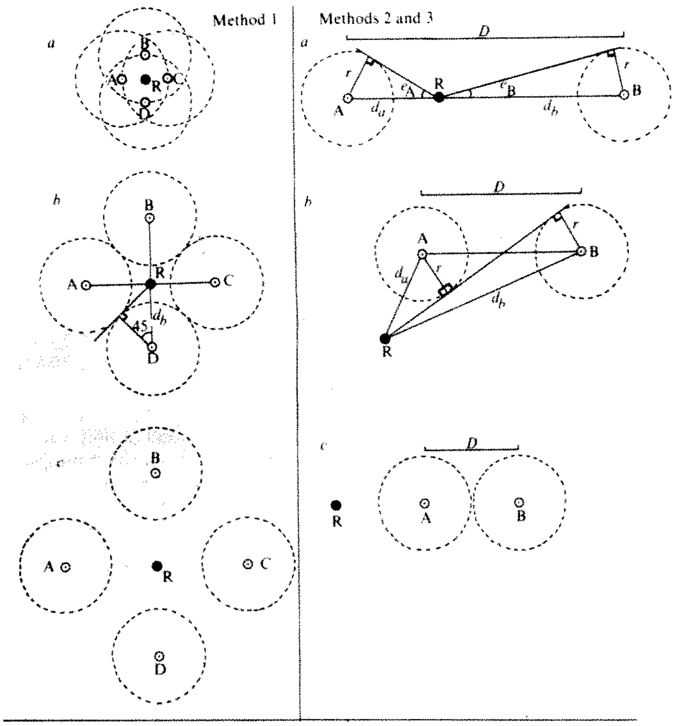

Fig. 1 Three mark-release/recapture methods for estimating the distance of response of moths to a light trap; 1—the increasing circle method. *a*, Four light traps are placed equidistant from a release point (R) at such a distance that the release point is within the response range (dashed circles) of moths to the light traps. The number of marked moths captured by the traps should be relatively high. *b*, As the four traps are moved further and further away from R, there comes a position first at which the edge of the response range withdraws from the release point and second, at which the edges of the response ranges of the four traps cease to overlap but just touch. Even at this position, however, the released moths cannot escape the circle of traps without entering a response range. The proportion of recaptured moths should therefore be the same as for *a*. *c*, Movement of the traps still further from R allows some moths to escape the circle of light traps by flying through the gaps between the response ranges. The proportion of moths recaptured should decrease as the distance of the traps from the release point increases. See Fig. 2(i) for the expected proportion of moths recaptured against distance of the traps from R. The radius of the response range is then given by 0.707 d_b (where 0.707 is the sin of 45° and d is the distance of each trap from the release point at position b). 2—The angle ratio method. a, When R is nearer one trap (A) than another (B), the angle (e_A) subtended to R by the response range of A is greater than the angle (e_B). Assuming that individuals leave R equally in all directions, the ratio (a/b) of marked moths recaptured in A and B should be e_A/e_B. This ratio is a function of r, the radius of the response range ($\sin e_A = r/d_a$; $\sin e_B = r/d_b$). For any given value of e_A/e_B the value of r can be determined by trial and error. 3—The masking method. Starting from the position used for method 2, let the distances d_a and d_b remain constant but let the distance (D) between the two traps decrease (*b*). As D decreases, the release point R swings around trap A. The ratio of marked moths recaptured in A and B should remain constant. This remains true even at the position shown (*b*) where a single line drawn from R is tangential to the response ranges of both A and B. Further decrease in D (*c*) causes the response range of trap B to be increasingly masked by the response range of trap A. The minimum distance possible for D and the maximum masking of B by A is reached at *c*. See Fig. 2*b* for the expected shape of the curve of a/b plotted against D. The point of inflection locates *b* from which, given d_a, d_b and D, r can be calculated:

$$r = \frac{4d_a^2D^2 - (d_b^2 - d_a^2 - D^2)^2}{8d_b^2 + 8d_a^2 - 4D^2}\;^{1/2}$$

Methods 2 and 3 therefore give two independent estimates of r: from the graph, the value (V) of a/b along its horizontal portion gives one estimate (method 2); the point of inflection locates *b* and gives another estimate (method 3).

moths orientate with respect to a light source; it seems intuitively that this distance should be fairly large. We present here the results of three experiments designed to determine the distance of response of free-flying moths to an artificial light source. Our results support Sotthibandhu's claim[4] that the effective range of a 125 W mercury vapour (MV) lamp is about 3 m. They also lead to speculation concerning the behavioural meaning of the light trap response in moths.

There was general agreement that the distance of response to a 125 W MV lamp was of the order of 0.5 km (on a moonless night) (see ref. 8 for review). The first attempt to measure the distance at which individual moths in the field orientate towards such a lamp (positioned 60 cm above ground level) was made by Sotthibandhu[4] who claimed that the distance was of the order of only 3 m. Using flying large yellow underwing moths, *Noctua pronuba*, tethered to apparatus that allowed flight direction to be monitored continuously, he showed that the distance of response to a ground-based light trap varied between 1 and 4 m and was a function of environmental variables such as cloud cover, ambient temperature, and Moon illumination. Further-

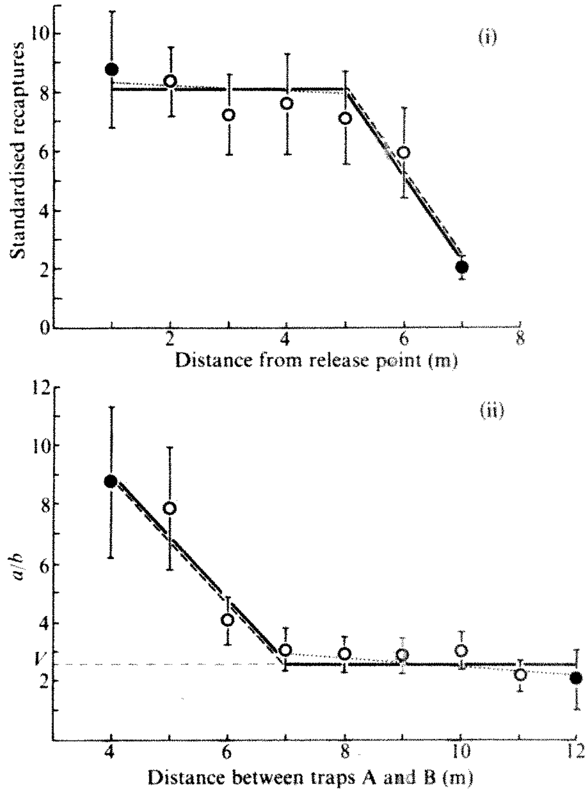

Fig. 2 Analysis of results presented in Tables 1 and 2. Experiments were carried out between 26 June and 26 July 1978 on a lawn at Woodchester Park Field Centre, Glos. Two species of moths, the large yellow underwing, *N. pronuba*, and the heart and dart, *Agrotis exclamationis*, were used. Moths to be marked and released were captured the previous night by the experimental light traps. After marking, without anaesthetisation, with a single dot of cellulose paint on the wing, the moths were stored (in communal keep nets in a cool room) until experimental release at about 22.30 GMT. The moths were released onto the ground within a 10-cm radius of the release point. Dots plus bars indicate means ± s.e.m. ●, means; ○, sliding means for the distance indicated ± 1 m. All regression analyses are for the raw data shown in Tables 1 and 2, not for the means and sliding means. (i) and Table 1 suggest (method 1) that the recaptures start to decrease beyond a release distance of 5 m. Calculated regression lines (dotted and dashed lines) are not significantly different ($P > 0.10$) from the expected (solid) lines. It may reasonably be concluded that the data do not depart significantly from the shape (solid line) predicted by the theory on which the method is based (Fig. 1), given that the response range radius is 3.5 m (that is, 0.707 × 5). (ii) Similarly, the data obtained by the masking experiment (Table 2, Methods 2 and 3) do not depart significantly from the shape predicted (solid line) by the theory on which the method is based (Fig. 1), given that a point of inflection occurs at a value for D of 7 m. The value (V) for a/b over the horizontal part of the curve is 2.09. This is obtained from Table 2 to avoid the effects of Bailey's correction for small numbers. V is calculated for $D \geqslant 7$ by taking the total number of marked moths recaptured in A ($a = 147$) and the total number of marked moths recaptured in B ($b = 42$), correcting for the total number of unmarked moths captured in each (1096 in A, 654 in B), giving $a = 0.134$ and $b = 0.064$, and then dividing a by b. Given that in our experiment $d_a = 4$ m and $d_b = 8$ m, this ratio of 2.09 gives a response range radius of about 2.2 m (Method 2). Given $d_a = 4$ and $d_b = 8$, a point of inflection at $D = 7$ gives a response range radius (r) of 2.7 m (Method 3). Summarising: the three estimates of response range radius are: method 1, $r = 3.5$ m; method 2, $r = 2.2$ m; method 3, $r = 2.7$ m. The three independent estimates of response range given by the three methods are therefore consistent both with each other and with the view that the two moth species studied respond only from a short distance of about 3 m.

Table 1 Effect of varying the distance of release from four equally spaced light traps on the recapture of marked moths (method 1)

			Capture/recapture data for four traps (A, B, C, D)

Trap A, 4 m from release point (R), Trap B, 8 m from R; D, distance between trap A and B in metres; M, number of marked moths released; r, number of marked moths recaptured, N, number of unmarked moths captured

* Calculated from a and b before they are rounded to 3 decimal places.

more, for each individual as it was brought nearer to the light, the change-over from celestial orientation[9] to light-trap orientation occurred suddenly at some threshold distance. The implications of such a short threshold response distance of moths to a light trap are far-reaching, particularly with respect to the use of light traps in survey work[2,7], in that, if it is correct, shifts of only a few metres in the position of a light trap could markedly influence the number and species of moths captured. However, it is inevitable that some initial reservations are felt over Sotthibandhu's results because he used tethered moths. There is thus a need for the short-distance nature of the light-trap response to be confirmed using free-flying individuals.

The theory behind our three experimental methods, all of which are based on mark-release/recapture, is presented in Fig. 1. The field procedure is described in the legend to Fig. 2 and the results are presented in Tables 1 and 2. The results are analysed and interpreted in Fig. 2. During the course of this work nearly 5,000 individuals of two species of moth were marked and released. The results (Fig. 2) for all three methods are consistent with the suggestion that moths only respond to a 125 W MV lamp from short distances (about 3 m). Why should moths respond to an artificial light source from such a short distance when it is clear from electroretinographic studies[10] that the light can be perceived from much greater distances?

It has been shown[9] that the angle of orientation (which is individual-specific and which may be anything within the range 0° ± 90° for individuals caught in a light trap) of an individual *N. pronuba* relative to an artificial light source is the same as the angle taken up by that individual relative to the Moon's azimuth. The implication is, therefore, that the light response of moths is a Moon-orientation response, a suggestion first made by von Buddenbrock[11] but which is no longer favoured generally[12,13]. If Buddenbrock was right, the problem remains of why the moths should respond to the Moon at a distance effectively of infinity whereas they respond to an artificial light source at a distance of only 3 m.

Using tethered moths, Sotthibandhu has shown[4] that the response distance to a 125 W MV lamp raised 9 m above ground level is much greater than for the same lamp only 0.6 m above ground level, being of the order of 10–17 m. The angle of elevation of the light source is therefore important, as would be expected if the light-response is a Moon-orientation response. When the light source is near the ground, it is below the height of most flying moths and individuals are often seen to fly overhead, a few metres above ground level, without apparently responding to the light. Others are seen suddenly to dive down to ground level. This behaviour is often a response to bats flying overhead[14] but also frequently occurs in the apparent absence of bats. If the diving response is a response to the light, it could be interpreted as an attempt to restore a Moon substitute, the artificial light, to an acceptable elevation, above the level of the moth's eyes, so that dorsal rather than ventral ommatidia are illuminated[9]. Once a moth is near or on the ground, of course, the elevation of the light can approach that of the real Moon, depending on the distance of the moth from the light. Perhaps the explanation for moths responding to a light 60 cm above ground level, at a distance of only 3 m is that at greater distances, even for low-flying moths, the apparent elevation is not a close enough approximation to that of even a newly risen Moon.

Angle of elevation cannot be the only factor involved in Moon recognition, however, otherwise, when the artificial light is raised 9 m above ground level the distance of response would be expected to be much greater than the 10–17 m observed. Spectral composition, light intensity and the physical size of the light are all factors that could also be important. The light bulbs used by us, which are the same as those used by Sotthibandhu[4], have a horizontal diameter of 7.5 cm and a vertical diameter of 12 cm. As the Moon changes phase its apparent horizontal diameter changes considerably but the vertical diameter is much more constant, subtending to a point on the Earth's surface an angle of 0.518° (diameter = 3,456 km; distance = 382,170 km). The vertical dimension of the light bulb used by us subtends the same angle to a point at a distance of 13.27 m. This is much nearer the distance of response (10–17 m) of a moth near the ground to an elevated (9 m above ground level) light source than is the distance (35–519 m, depending on Moon phase, latitude, and so on[8]) at which the light source has the same level of illumination as the Moon.

We suggest, therefore, that the light-trap response of moths results when the moth ceases to recognise that the artificial light is not the Moon, and that the most important features used in this recognition are first, the elevation, and second, the vertical diameter of the light source. Level of illumination and spectral composition may also be involved[5,8] but are suggested here to be far less important.

On the interpretation of the light-trap response offered here, light traps should catch only those individuals that are in the physiological state in which they would make use of Moon orientation. Most often these will be individuals that are in the process of, or just initiating or terminating, migration. This could explain why light traps do not capture all species of moths in the vicinity[2] (non-migrants not showing the light-trap response) and why males of most species predominate in light-trap catches, males probably being more migratory than females[15]. It could also explain why a better correlation is obtained between light trap catch and volume of migration as determined by radar[3] than between light-trap catch and suction-trap catch[2].

Male mating experience and competitive courtship success in *Drosophila melanogaster*

MULTIPLE copulations by *Drosophila melanogaster* males reduce their fertility[1], even though these males will continue to court and mate after four or five successive matings. This sterility involves depletion of the accessory glands and not of sperm supply[2] and is only temporary, for when these males are mated 2 or 3 h after the onset of sterility, they once again transfer sperm. A female *Drosophila* would maximise her reproductive fitness by mating with a male which transfers the most sperm; however, virgin females will copulate with temporarily sterile males when placed in a single-pair situation. Although female *Drosophila* are capable of discriminating mates on the basis of genotype differences[3], it is not known whether they will selectively copulate with fertile males in competition with temporarily sterile males of the same strain. In the experiments reported here, we have examined the relative mating success of experienced males with temporarily reduced fertility and virgin males from the Canton-S strain of *D. melanogaster.* The data show that when a virgin female is placed with a virgin and an experienced male, she tends to mate with the virgin male. Examination of some possible factors for increased virgin male success, such as time until initiation of courtship, amount of time spent courting, and overall mating speed, showed that for the courtship parameters measured, virgin and experienced males are equal.

Flies were raised on standard cornmeal–molasses–agar medium at 24 ± 1 °C. Virgin flies were separated by ether anaesthetisation and stored until 3 d old. Virgin females were then placed individually into 8-dram shell vials containing one experienced male and one virgin male. Males were distinguished by wing clipping[3], which was done at the time of collection to avoid the need for a second anaesthetisation. Clipping was alternated between groups to avoid any possible effects on the results. Small clips have not been found to alter mating in the present study (see below) or in previous studies[4]. All subsequent handling of flies was done by aspiration.

Table 1 Number of offspring produced by males mating three successive times

Mating	Mean no. of offspring per mating per male*	No. of males
1	288.0 ± 17.4	33
2	296.1 ± 28.2	31
3*a*	194.7 ± 23.6	30
3*b*	206.0 ± 21.0	29
3*c*	303.2 ± 18.8	35

a, Males mated immediately after the second mating; *b*, males rested 1 h after the second mating; *c*, males rested 24 h after the second mating.

* A Duncan multiple range test places these data in two statistically significantly different subsets ($P < 0.01$) where offspring number from mating 1, 2 and 3*c* are in one subset, and offspring numbers from matings 3*a* and 3*b* are in another subset.

Three series of experiments were carried out. In series 1, 'experienced' males were obtained by placing virgin males in a shell vial containing one virgin female. Immediately after copulation, the male was placed with another virgin female. During the initial phase of the experiments, 97% of the original males had mated the first and second times by the 1-h cut-off period. After the second mating, each experienced male was placed with a virgin male in a clean shell vial, and a virgin female was introduced. Courtship latency, duration of courtship, successful male and duration of copulation were recorded. Vials showing no mating in 1 h were discarded. In series 2, males were handled the same way except that they were stored alone for 1 h between the second and third matings to eliminate any possible effects of postcopulatory preening or inactivity. In series 3, males were stored for 24 h before the third mating and tested with virgin males of the same age.

The number of offspring produced by males mating three times was determined by saving the females from each of the three matings and counting their progeny (Table 1). Fertility is greatly reduced at the third mating when this occurs within minutes of the second mating or when males are rested for an hour. When males are rested for 24 h after the second mating,

0028-0836/78/0276—0821$01.00

their fertility rises to levels seen in once-mated males. The total number of offspring produced by virgin males is slightly less than reported elsewhere[2]. However, the present study used a different wild-type strain.

Table 2 shows the relative mating success of experienced males. The data for the nine replications ($n = 15-20$ per replication) in series 1 were pooled following testing for homogeneity[5]. The numbers shown for series 2 are pooled values for nine replications, and for series 3 eight replications. In series 1 and 2, virgin males had a distinct mating advantage. In series 3, no advantage existed.

Table 2 Relative mating success of virgin and experienced *D. melanogaster* males

		Male chosen				
Series	% Mating	Virgin	Experienced	Total	X^2	P
1	95	115	65	180	13.88	<0.01
2	96	104	74	178	5.02	<0.05
3	96	84	91	175	0.28	NS

Overall clipping $x^2 = 0.965$. NS, not significant.

It has been reported that in *Drosophila*, the females 'decide' if and with which male a mating will take place[3,6]. Obviously, these 'decisions' depend on various sensory cues from the males. It is known that males which spend less time courting have a reduced mating success[7]. However, the disadvantage of the males with reduced fertility in the present study could not be explained by any reduction in observable courtship activity. Experienced males from series 1 and 2, whether successful or not, equalled virgin males in (1) being first to begin courtship, and (2) the proportion of time spent not courting. The average courtship times in series 1 and 2 were 6.01 ± 0.29 min for successful virgin males and 5.97 ± 0.33 min for successful experienced males ($t = 0.024$, NS). The duration of copulation was 20.61 ± 0.91 min and 21 ± 1.06 min for virgin and experienced males, respectively ($t = 0.76$, NS).

Although the virgin and experienced males of series 1 and 2 were of the same age and strain, they are in some way perceived as differing from each other by females. As the standard tests of courtship which would reflect differences in male vigour cannot explain the differences in success of the two types of males, the possibility that they are characterised by different olfactory stimuli[8], or patterns of organisation of courtship elements[9] should be investigated. Some stimuli from the males must somehow be influencing the mate selection process of the females. Any mechanism which results in females discriminating the level of fertility of prospective mates would certainly have a selective advantage. Other species should be studied to determine how widespread this phenomenon is.

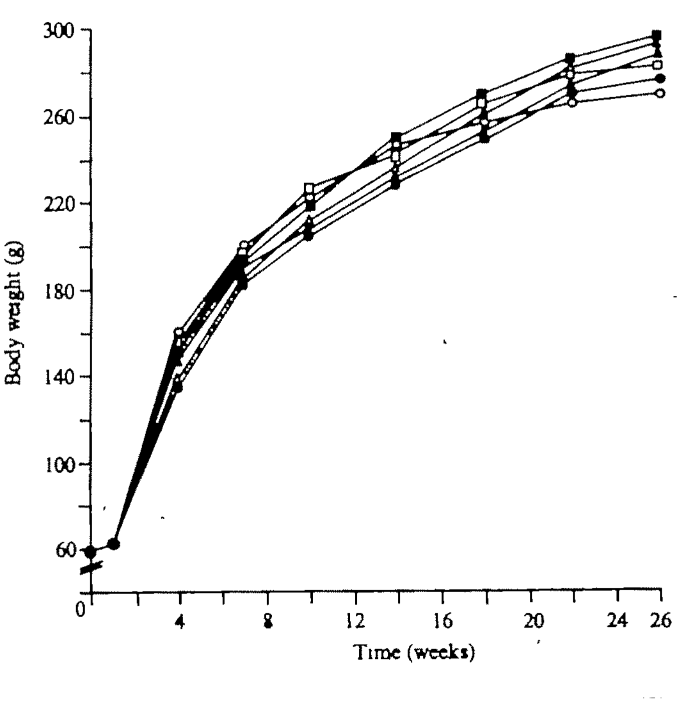
Co-carcinogenic effects of dietary cholesterol in experimental colon cancer

COLORECTAL CANCER is now the most common internal malignancy in the US (ref. 1), but its aetiology is unknown. Western dietary factors are likely to be implicated[2,3], and high fat diets correlate well with the geographical incidence of colon cancer[4–6]. Patients with colon cancer have high levels of faecal bile acids and cholesterol[7] as do patients with diseases known to be associated with colon cancer, for example, familial polyposis[8] and ulcerative colitis[9], and also other high-risk populations[10]. It is thought that faecal bile acid and cholesterol metabolites may act as promoters, co-carcinogens or carcinogens in large bowel tumorigenesis[11–13]. As cholesterol is the obligatory precursor of the bile acids[14], we have tested the ability of dietary cholesterol to promote the induction of colon cancer by dimethylhydrazine (DMH) in the rat. We report here evidence from an animal study that cholesterol is a potent dietary co-carcinogen.

The experimental method and diets used are detailed in Table 1. The effects of a single dietary variable, cholesterol, was investigated on the induction of colon cancer in two identical groups of rats, both fed on Vivonex, a cholesterol-free, chemically defined liquid diet. One group (V) received unmodified Vivonex, and the other group (VC) received Vivonex with added cholesterol. The third dietary group (S) was included solely for comparison as a carcinogen-injected control group and was fed a standard formula solid diet. By design, all three diets were fibre-free and provided equivalent caloric intakes.

The results were analysed after 56 weeks' observation. During the first 6-month period, animals on all dietary regimens maintained comparable weight gains (Fig. 1). Any observed differences between groups are therefore unlikely to be attributable to the effects of caloric restriction. Comparisons beyond 6 months are inaccurate, because of variations between sick animals in relation to appetite and weight loss due to the induced colon cancers. At 56 weeks, all control animals were alive and well, except for a single rat fed on Vivonex plus cholesterol

Fig. 1 Growth curves showing weight gain of rats on various dietary regimens. Each point represents a mean weight of the 10 rats in each group. Standard deviations have been omitted for clarity. Statistical comparison shows no significant differences between groups at 26 weeks ($F = 0.28$, d.f. = 5,54, $P > 0.10$). Groups: ○, S, ●, V control, △, V; ▲, VC; □, VC control; ■, S control.



which died of pneumonia at 42 weeks with a tumour-free colon. All the remaining deaths occurred in the carcinogen-treated rats and (with two exceptions cited in Table 2) all were attributable to histologically confirmed adenocarcinoma of the colon, or its complications. All animals either died spontaneously (44.4%) or fulfilled one of the recently published[17] objective criteria for killing (55.6%) (ref. 17).

Examination of the results (see Figs 2, 3 and Table 2) shows that DMH-treated animals fed on the cholesterol-free diet Vivonex showed a highly significant increase in both time to tumour presentation ($P < 0.001$) and survival ($P = 0.001$) when compared to carcinogen-injected controls fed on a standard diet. This suggests that Vivonex protected against DMH carcinogenesis. Comparison between the two groups of Vivonex-fed animals (groups V and VC) shows that the addition of cholesterol to Vivonex significantly reduced both the time to tumour presentation ($P < 0.001$) and survival ($P = 0.008$) of group VC, as well as increasing the incidence of metastases ($P = 0.028$). The latter finding was particularly striking (see Table 2) as 67% of group VC animals had abdominal carcinomatosis at necropsy. Distant metastases are uncommon in this model[20] and in our experience the incidence rarely exceeds 20%. This suggests that the addition of cholesterol to Vivonex not only abolished the protective effect of Vivonex, producing similar tumour indices in group VC to those of group S, but also enhanced the spread of the induced colonic cancer. These findings are attributable only to the single experimental variable, the provision of cholesterol in the diet.

Table 1 Dietary intake and experimental method

Dietary component	Calculated range of daily intake in each dietary group (mg per adult rat per day) Vivonex[*] (V)	Vivonex plus cholesterol[†] (VC)	Standard[‡] (S)
Cholesterol	0	6–9[§]	3–5
Saturated fat	0	0	105–140
Unsaturated fat	65–98	65–98	363–484
Kilocalories per kg	750	750	3580
Consumption per adult rat per day	60–90 ml	60–90 ml	15–20 g
Kilocaloric intake per adult rat per day	45–68	45–68	54–72

Sixty weanling inbred female Wistar rats (A. Tuck) weighing 60–70 g were weaned on to a standard diet (41B), for one week to establish normal colonic function and bacterial colonisation. Thereafter, they were randomly allocated in groups of 20 to one of the three dietary regimens. After a further two weeks on their respective diets, half the animals ($n = 10$) in each group were injected with carcinogen DMH dihydrochloride (97%) (Aldrich) at a dosage of 40 mg per kg body wt per week subcutaneously for 13 weeks and prepared according to the method of Filipe[16]. The other half received equivalent volumes of saline preservative to act as controls. They remained on these diets for the rest of their lifetime. Animals were housed in temperature-controlled quarters in subgroups of five in suspended cages which had open-mesh, wire floors designed to prevent coprophagia. They were weighed weekly and inspected daily for signs of illness or colonic disease (for example, rectal bleeding with positive faecal occult blood test, tumour prolapse per rectum, diarrhoea, ascites or colonic obstruction with abdominal distension). When moribund, animals were isolated to prevent cannibalisation, and either died spontaneously or were painlessly killed when they fulfilled objective criteria for death[17]. Complete necropsies, including the selection of specimens for histological examination, were performed on all animals. Four tumour indices (see Table 2 for definitions) were measured in each animal during this *in vivo* study. The time to tumour presentation and survival were analysed statistically by the log rank method of Peto *et al.*[18]

[*] Vivonex was prepared each day as follows: 10 sachets (each providing 300 kcal) were dissolved in 3 l of fresh water, mechanically stirred in a 5 l conical glass flask until fully dissolved, and made up to a final volume of 4 l. It was then divided into 2 equal volumes, to one of which 200 mg cholesterol was added, and both volumes were stirred for 1 h. The liquid diets were then dispensed into standard 540-ml glass feeding bottles and offered to the animals at the same time each day.

[†] 99.9% free of solid impurities (BDH Chemicals).

[‡] Formula Diet 41B, in pellet form (BP Nutrition). This diet was specially prepared to exclude all crude and dietary fibre.

[§] This dosage was selected to approximate, on a body weight basis, the daily cholesterol intake of a 70 kg man breakfasting on two fried eggs and two rashers of bacon, that is, 1,000 mg per day[15].

Cholesterol has not yet been shown to be a colon carcinogen, although there is evidence[21], recently disputed[22], that it is sarcomagenic in mice. However, the control animals receiving added dietary cholesterol in our experiment are alive and clinically tumour-free, and the observed effects cannot therefore be ascribed to cholesterol *per se*. As the augmentation of DMH colon tumour induction by cholesterol is within Berenblum's definition of 'co-carcinogenic action'[23], the effects can be attributed to cholesterol acting as a dietary co-carcinogen. We conclude, therefore, that dietary cholesterol facilitates the development, growth and spread of this experimental colon cancer.

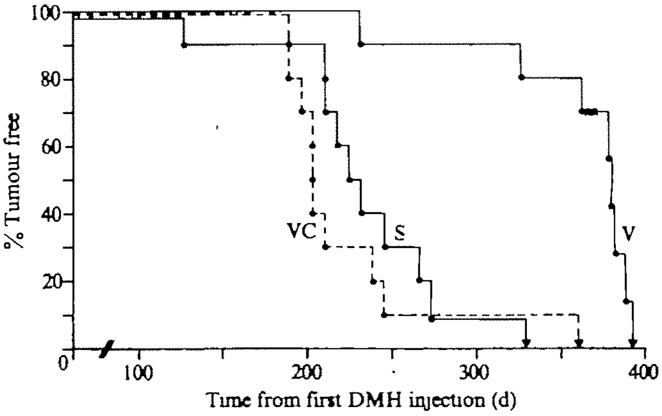


Fig. 2 Life table of proportion of tumour-free animals as a function of time after first injection of DMH. ●, Tumour presentations, ×, deaths without presentation. Statistical analysis of time to tumour presentation[18]:

Group	Observed nos presenting (O)	Extent of exposure (E)	Ratio (O/E)
V	8	17.70	0.45
VC	10	4.21	2.38
S	10	6.09	1.64

V against VC, $\chi^2 = 14.16$, 1 d.f., $P < 0.001$; VC against S, $\chi^2 = 0.27$, 1 d.f., $P > 0.10$; V against S, $\chi^2 = 13.59$, 1 d.f., $P < 0.001$.

Evidence from other animal studies has shown that high fat diets[12,24–26] and bile salts[27,28] promote the effects of several large-bowel carcinogens, and that animals on such high fat diets excrete more faecal neutral sterols and bile acids than do controls[12]. However, there is disagreement as to the type of dietary fat responsible for the promotion. Studies comparing the relative role of saturated with unsaturated fats did not detect differences in colon tumour incidence[25,29], but a recent report associates an increased tumour yield with a diet high in unsaturated fat and cholesterol[26]. Such discrepancies are due, in part, to the fact that many experimental diets contain mixtures of fats and variable amounts of non-fat components such as fibre which may exert independent effects[25]. The use of Vivonex obviates this problem, as it contains neither cholesterol, saturated fats nor dietary fibre and therefore allows carefully controlled dietary alterations. It has been used before in this model by Castleden[30], but the experiment was terminated at 24 weeks; the Vivonex diet used was not fibre-free, as the rats had been eating sawdust as well.

Two salient questions are raised by our results. The first relates to the mechanism whereby Vivonex feeding protects against DMH colon carcinogenesis, and the second to the mechanism whereby cholesterol overcomes this protective effect and facilitates tumour development. The effects of both Vivonex and cholesterol on DMH metabolism are unknown. Vivonex has been shown in humans to affect faecal bulk, transit time and flora, as well as reducing the levels of faecal bile acids and cholesterol metabolites[31], and some or all of these factors may be involved. However, as our evidence demonstrates that the addition of cholesterol to Vivonex overcomes the protective effect, the simplest explanation is that Vivonex protects because it lacks cholesterol. The protection is clearly incomplete, as Vivonex-fed rats do eventually develop colon cancers. This could be attributed to endogenous synthesis of cholesterol (or its metabolites), or the presence of a small amount of polyunsaturated fat in Vivonex, or a combination of the two. However, it is possible that the induced colon cancers could progress spontaneously in the complete absence of cholesterol, both exogenous and endogenous, due either to random biological accident or to another qualitatively different cause.

The relevance of animal data to the human situation is debatable, but the concepts are useful, particularly when seen against the general framework of multi-stage tumour models. Modern theorists[32,33] envisage a multi-stage transition from a normal to a cancerous state. In general, the early stages seem to be initiated by mutational events, with subsequent stages proceeding either randomly, by biochemical accident, or at a rate determined by various extrinsic agents. In this context, a parallel may be drawn between animal and human colon carcinogenesis: in the animal model, DMH (a mutagen) presumably affects one or more early stages, and dietary components such as fat and cholesterol one or more later stages. Similarly, whilst the early (presumably mutational) stage in the genesis of human colon cancer is unknown, the disease does seem to involve multi-stage processes[34], and an interpretation of the data implicating dietary fat and cholesterol in man would be that these dietary components are analogous rate-determining extrinsic agents affecting the later stages.

Although it is possible, in both animals and man, that the different stages could proceed in the absence of dietary fat or cholesterol, the experimental and epidemiological evidence is consistent with the interpretation that these dietary components are associated with an apparent acceleration of the processes involved. Our observations corroborate this concept, and specifically suggest that dietary cholesterol is a factor determining the rate of development of experimental colon cancer. If this applies to man, as the metabolic evidence would suggest, then human colon cancer may be a preventable disease.

We thank Mrs F. Briscoe and Eaton Laboratories for supplying and sharing the cost of Vivonex, Mr P. Luther for technical assistance, the animal house staff, Miss Susan White of the MRC Statistical Research and Services Unit and Miss Diana Wilson for typing the manuscript. Protease inhibitors suppress radiation-induced malignant transformation *in vitro*

LITTLE is known about the mechanisms of carcinogenesis. The fact that most carcinogens are mutagenic has led to speculation that the primary step in cancer induction may be mutational[1,2]; there is evidence from both *in vivo*[2] and *in vitro*[3] studies that a strong correlation exists between the mutagenicity and carcinogenicity of an agent. Mutagenic and carcinogenic agents, both physical and chemical, also produce similar kinds of DNA damage and repair[4]. Radiation-induced mutagenesis in some bacterial cells requires an error-prone DNA repair system[5,6], and there is now some evidence that error-prone DNA repair may be involved in the malignant transformation of cells by radiation[7,8]. Protease inhibitors have been shown to suppress specifically both error-prone repair and mutagenesis in bacterial cells[9,10], as well as to inhibit carcinogenesis *in vivo*[11,12]. We report here that the protease inhibitors antipain and leupeptin will suppress radiation-induced transformation *in vitro* as well as inhibit two-stage transformation *in vitro* using radiation and the promoting agent, 12-O-tetradecanoyl-phorbol-13-acetate (TPA).

We used a C3H mouse-embryo-derived cell line (10T$\frac{1}{2}$ clone 8) isolated and characterised by Reznikoff *et al.*[13,14], and adapted for studies of radiation transformation[7,15,16]. In some experiments, a BALB/3T3 mouse line designated A31-11 was used. Concentrations of the protease inhibitors used were nontoxic, either with or without radiation exposure, and have been shown not to affect growth, RNA or protein synthesis in bacterial[9] or mammalian cells[18–20].

The influence of antipain and leupeptin on X-ray induced transformation is shown in Table 1. In these experiments, the inhibitors were present for the entire post-irradiation expression period. As can be seen, antipain not only suppressed X-ray-induced transformation but also completely abolished transformation enhanced by TPA. Similarly, leupeptin suppressed radiation transformation enhanced by TPA, although this protease inhibitor did not seem to be as effective as antipain. To determine whether these protease inhibitors were effective in suppressing radiation transformation when present for only a short post-irradiation interval, experiments were carried out with antipain present only during the 5-d or 1-d period following radiation exposure. Antipain at 1 mM (600 μg ml^{-1}) reduced transformation from 2.0×10^{-3} to $<3.2\times10^{-4}$ when present for 5 d and to 5.5×10^{-4} when present for only 1 d following 600 rads.

A preliminary experiment was carried out with A31-11 mouse BALB/3T3 cells to determine whether the suppressive effect of antipain was cell line-specific. These results are shown in Table 2. Again, incubation with antipain (50 μg ml^{-1}) throughout the expression period completely suppressed transformation induced by 100 or 400 rad of X rays plus TPA exposure.

Endogenous proteases have been implicated previously in the mechanism of tumour promotion[21], and protease inhibitors have been shown to suppress two-stage carcinogenesis *in*

Table 1 Effects of 6 weeks post-irradiation exposure to antipain and leupeptin on X-ray transformation of 10T$\frac{1}{2}$ cells with and without promotion by TPA

Treatment	Expt. no.	PE %	Total no. cells at risk	Total no. transformed foci*	Transformation frequency per viable cell ($\times10^{-4}$)*
Controls (no treatment)	1	32.5	3,120	0	<3 2
	2	29.3	4,395	0	<2.3
Antipain alone	1	32.2	3,088	0	<3.2
	2	32.3	4,845	0	<2.1
600 rads	1	3.0	2,160	5	23.1
	2	2.4	7,200	11	15.3
600 rads + antipain	1	3.4	3,264	1	3.1
	2	2.7	3,120	0	<3 2
600 rads + leupeptin	1	3.8	3,192	1	3.1
	2	2.9	3,780	2	5.2

	2	5.7	7,140	22	30.8
400 rads + TPA + antipain	1	7.4	1,332	0	<7.5
	2	7.7	4,620	0	<2.2
400 rads + TPA + leupeptin	1	10.6	5,088	2	3.9

Details of experimental techniques for radiation transformation experiments using 10T$\frac{1}{2}$ cells have been described elsewhere[7,15,16]. Stock cultures were maintained in 60 mm Petri dishes and were passed by subculturing at a 1 : 20 dilution every 7 d. The cells used were in passages 9–14. They were grown in a humidified 5% CO_2 atmosphere at 37 °C in Eagle's basal medium supplemented with 10% heat-inactivated fetal calf serum and antibiotics. Cells were irradiated 24 h after seeding, and incubated in fresh medium containing TPA and/or protease inhibitors immediately afterwards. Antipain and leupeptin added at 50 μg ml^{-1}; TPA at 0.1 μg ml^{-1}.

* Types 2 and 3 foci were scored as transformants, as described by Terzaghi and J.B.L.[15].

0028-0836/78/0276-0825$01.00

Table 2 Effect of antipain on oncogenic transformation induced in 3T3 cells by X rays plus TPA

Treatment	Total no. cells at risk	Total no. transformed foci	Transformation frequency ($\times 10^{-4}$)
400 rads	60,500	66	10.9
400 rads + antipain	43,450	14	3.2
400 rads + TPA	52,800	91	17.2
400 rads + TPA + antipain	50,050	0	<0.2
100 rads + TPA	34,400	29	8.4
100 rads + TPA + antipain	33,500	0	<0.3

Stock cultures were passaged as for 10T½ cells. Cells were seeded 24 h before irradiation at densities which yielded about 4,000 viable cells per 100 mm Petri dish. They were grown in Eagle's minimal essential medium supplemented with 10% heat-inactivated fetal calf serum and antibiotics. Transformed foci were scored at 4 weeks[17]. Antipain was added at 50 μg ml^{-1} (0.08 mM) and TPA at 0.1 μg ml^{-1}.

vivo[11,12]. It is possible, therefore, that the suppression of radiation transformation by these protease inhibitors is due entirely to an effect on the promotion stage of transformation (or carcinogenesis). This hypothesis is supported by the observation that almost complete suppression occurred in the presence of TPA. However, the fact that antipain was also effective in inhibiting transformation at early stages (within the first 1 or 5 d of irradiation) argues against this hypothesis, and suggests that an effect on DNA repair processes might be important in its action. TPA is ineffective in enhancing X-ray transformation unless it is present for at least 14 d or the entire proliferative phase of expression after irradiation (unpublished data).

Mutagenesis in some bacterial cells requires an error-prone DNA repair ('SOS repair') function[5,6]. It has been postulated that the induction of mutations in mammalian cells may also be associated with an error-prone DNA repair process[22,23]. There is some evidence that DNA repair mechanisms operating within the first few hours of radiation exposure may be involved in the induction of malignant transformation by X irradiation in 10T½ cells[7,8]. The theory that proteases have the ability to cleave suppressors of error-prone repair in bacteria and thus induce this type of repair[5,6,9] suggests that protease inhibitors might inhibit malignant transformation *in vitro* by inhibiting error-prone repair. Thus, it is possible that the action of protease inhibitors on a DNA repair process may be a mechanism for our observed suppression of radiation transformation. Further investigation of this hypothesis will require a careful examination of the post-irradiation intervals during which antipain has its greatest effect on transformation, as well as its effect on specific molecular repair processes during these times.

In any event, the present results offer *in vitro* confirmation for the suppressive effect of protease inhibitors on carcinogenesis *in vivo*. They suggest that a further examination of the mechanisms of action of these agents may offer valuable insights into mechanisms of carcinogenesis.

We thank Dr Miroslav Radman for suggesting these experiments to us, Mr Gary Murphy for expert technical assistance, Dr T. Kakunaga for the A31-11 line and Dr Walter Troll and the US-Japan Cooperative Cancer Research Program for providing the antipain and leupeptin used in this study. This research was supported by NIH grants CA-22704 and ES-00002.

Immunological properties of the surface of parasitic nematodes

THE surface of parasites seems to be especially important in the intricate relationship which is known to exist between these organisms and their hosts. This is particularly clear in the case of African trypanosomes, which are able to vary the antigenic glycoproteins of their surface sequentially during infection[1]. It is also known that the surface of schistosomes changes during infection in parallel with alterations in the susceptibility of this trematode to the action of immunity[2]. By comparison with these and other parasites, little is known of the properties of the surface of nematodes nor of its role in the host–parasite interaction. Both free-living and parasitic nematodes are bounded by a non-cellular cuticular layer which is probably living because it may contain, for example, enzymes and haemoglobin[3]. The cuticle, which is shed and replaced as the nematodes pass through the various moults in their life cycle, consists of fibrous collagen-like proteins, thought unlikely by some authors to be highly immunogenic in the host[4]. However, we now report that

Table 1 Viability of *T. spiralis* newborn larvae cultured *in vitro* for 30 h with peritoneal cells and immune serum

Source of serum	Source of peritoneal cells	% Parasites dead*
Normal rat	Normal rats	2.2
	Infected rats	0.5
Normal rat, heat inactivated	Normal rats	5.8
	Infected rats	2.1
Immune rat	Normal rats	93.7
	Infected rats	98.6
Immune rat, heat inactivated	Normal rats	66.6
	Infected rats	36.1

Immune serum was taken at either the 18th or 24th day after a primary infection with 4,000 infective larvae. Inactivation was achieved by maintaining serum at 56 °C for 1 h. Cells from infected rats were taken from the peritoneal cavity of rats 24 d after a primary infection and prepared as described in Fig. 1. This suspension contained 35–45% eosinophils, 5% mast cells and 50–60% mononuclear cells.

* 150 Parasites per replicate were observed with at least four replicates in each group. The parasites were considered to be dead when they were completely immobilised and had visible signs of deterioration in their internal organs.

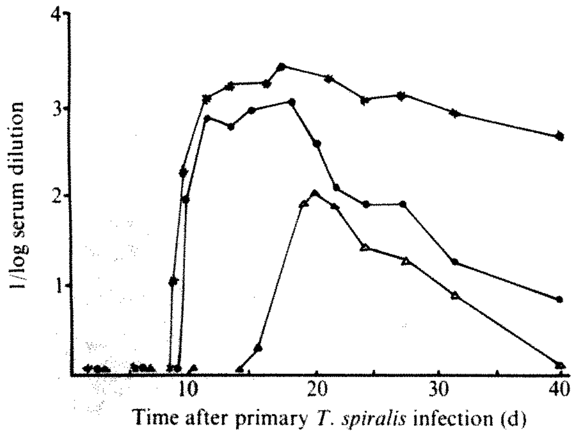

Fig. 1 Serum studies in August rats infected with 4,000 infective larvae of *T. spiralis*. The time after infection to appearance of antibodies mediating *in vitro* adherence of a population of peritoneal cells to newborn larvae (△), infective larvae (*) and adult parasites (●). Sera obtained at various times after infection were inactivated by heating at 56 °C for 1 h. The peritoneal cells were incubated on a plastic surface for 2 h and the non-adherent supernatant cells used in this assay. The parasites were prepared by standard methods[13]. 0.3-ml cultures were set up in flat-based microtitre trays[5,6] to provide a cell:parasite ratio of 2,500:1 for newborn larvae, 4,000:1 for infective larvae and 8,000:1 for adult worms. These cultures were incubated at 37 °C for 90 min before assessing the cell adherence to the surface of the parasites by microscopic observation. The end point of the assay was taken as the serum dilution in which 50% of the parasite's surface area was covered with cells. The adherent cells were identified by staining with Giemsa and with chromotrope R, the distribution being approximately 95% eosinophils and 5% mast cells. The points indicated represent the means of at least three experiments, each carried out in triplicate. The s.d. value at each point did not exceed 0.25 except with infective larvae on days 18 and 20, where the s.d.'s were 0.7 and 0.4, respectively. With newborn larvae the values were less than 0.25 except on days 18 and 20 where they were 0.4 and 0.6.

the serum of animals infected with the nematodes *Trichinella spiralis* and *Nippostrongylus brasiliensis* contain antibodies to nematode cuticle, each specific to the surface of a particular stage in the life cycle of the parasites and capable of mediating attack by inflammatory cells against the nematode surface.

The presence in the serum of rats of factors interacting with the surface of nematodes was assessed by studying the adherence to the worms *in vitro* of peritoneal cell populations obtained from normal August rats, as described previously[5,6]. The cell populations used in this study were obtained by incubating peritoneal cells on a plastic surface for 2 h at 37 °C and collecting the non-adherent cells which consisted of 60–80% eosinophils, 15–20% mast cells and 5–20% mononuclear cells. Initial studies showed that even in serum freshly obtained from uninfected rats, cells adhered to the surface of some but not all stages in the life cycle of the nematodes studied. In dilutions of fresh normal serum, cells adhered to infective larvae of *T. spiralis* and *N. brasiliensis* to a titre of 1/300 and to adult worms of both species to a dilution of 1/60, but did not adhere to the newborn larvae of *T. spiralis*, which is the stage shed by the viviparous mature females of this species. Adherence was markedly reduced after the normal serum had been inactivated by heating at 56 °C for 1 h or had been treated with zymosan (5 mg per ml serum; Zymosan A, Sigma)[7].

These results show that the surface of infective larvae and adult worms activate complement but that the cuticle of newborn *T. spiralis* larvae does not have this property. However, heat-stable factors which cause adherence of the eosinophil-rich cell population to all stages of these parasites occur in the serum of infected animals. Figure 1 shows the occurrence of these factors in the serum of rats infected orally with 4,000 *T. spiralis* infective larvae. The appearance and maximum titre of these factors were different for each stage of the parasite, suggesting the presence of antibodies specific for each life-cycle stage. Adsorption studies confirmed this. When serum taken from rats 14 d after infection was absorbed with either infective larvae or adult *T. spiralis*, the serum factor mediating cellular adherence to the homologous but not heterologous life-cycle stage was removed (Fig. 2). Similar adsorption and time-course studies have shown that the serum factor mediating cell adherence to *N. brasiliensis* infective larvae differs from that mediating adherence to adult *N. brasiliensis*[8]. Because of their intense specificity for each stage, we assume that these serum factors are antibodies.

Although antibodies to the surface of nematodes have frequently been described using such methods as immunofluorescence[9,10] or cell adherence[6,11,12], their significance in terms of the nature of the parasite surface and its role in the host–parasite reaction has not been assessed. Further studies using serum and cells from normal or infected rats showed that the adherence of cells in the presence of serum from infected animals may have a lethal effect on these parasites at least *in vitro*. *T. spiralis* newborn larvae were killed after incubation for 25–35 h in the presence of serum from either infected or uninfected donors (Table 1). Fresh normal serum did not affect the viability of the parasites even in the presence of cells. However, the lethal effect of cells and the serum factors from infected animals was greatly enhanced when freshly collected, rather than heat-inactivated, serum was used. Thus, complement seems to affect newborn larvae of *T. spiralis* only in the presence of antibody. Whether or not cells must adhere to produce damage has not yet been clearly determined; however, dead or dying larvae always had adherent cells, generally eosinophils. Preliminary experiments with purified cell suspensions implicate this cell type as an effector cell in causing damage to newborn larvae in this *in vitro* model. The poorer ability of the cells from infected animals to damage larvae may therefore be due to the lower proportion of eosinophil leukocytes in these cell suspensions. A percentage of infective larvae of *T. spiralis* and *N. brasiliensis* can also be damaged by incubation in fresh serum taken from infected animals together with peritoneal cells, but we have not yet fully defined the parameters of this reaction.

This study has revealed three features of the surface of nematode parasites. The surface of infective larvae and adults of *T. spiralis* and *N. brasiliensis* may activate complement, but the surface of newborn larvae does not have this property. During

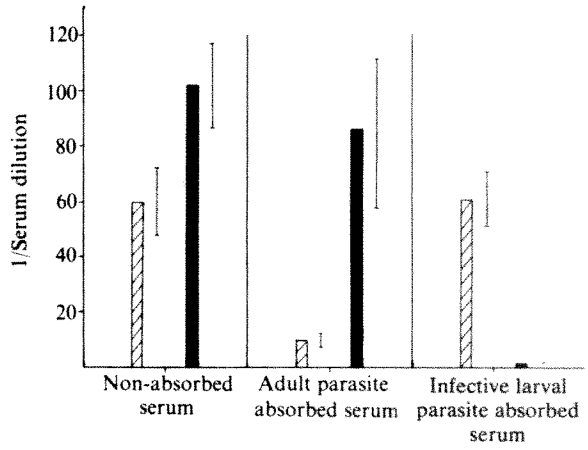

Fig. 2 Adsorption studies to show the specificity of the serum factors mediating cell adherence to *T. spiralis*. Serum obtained 14 d after infection with 4,000 *T. spiralis* infective larvae was assayed for its ability to mediate cell adherence before and after adsorption with adults (☐) or infective (■) larvae. An equal volume of freshly prepared parasites was added to a 1 in 3 dilution of the previously heat-inactivated serum and incubated at 37 °C for 90 min. The supernatant was then assayed as described in Fig. 1; s.d. values are expressed as bar lines.

infection, each stage in the life cycle of *T. spiralis* or *N. brasiliensis* stimulates antibodies which are specific for the surface of that stage only. Finally, in the presence of these antibodies, the parasites are vulnerable to attack and may be killed by peritoneal cell populations enriched in eosinophils, especially in freshly collected serum. Variations in the interaction between the host and different parasitic stages of an infecting nematode are likely to be due in part to differences in the interaction of these stages with complement, antibody and inflammatory cells.

Interferon inhibits the release of plasminogen activator from SV3T3 cells

INTERFERON, as well as inducing an antiviral state, can modify certain other cell characteristics. For example, it has been shown to inhibit cell proliferation[1–4] and release of C-type virus[5,6], and to enhance the expression of H-2 antigens[7,8] and the amount of glycoprotein on the cell surface[9]. These effects might be explained by decreased release of cell-surface components into the medium. Similarly, the expression of a glycoprotein on the cell surface has been related to the growth state of cells[10], which can be explained in part by differential release[11,12]. We have followed up this suggestion by examining the effect of interferon on the release of plasminogen activator (PA) by a line of simian virus 40 transformed Swiss 3T3 (SV3T3) cells. Our results, reported here, indicate that interferon inhibits the release of PA by SV3T3 cells.

First, to establish the sensitivity of SV3T3 cells to the anticellular activity of interferon, we grew cells in the presence of 50, 500, or 5,000 units ml^{-1} of a crude preparation of interferon[13]. Cell numbers (day 3) were reduced by 15, 40, and 50%, respectively, by these doses. These results were confirmed using the semi-purified mouse L cell interferon (3×10^7 NIH units per mg protein, obtained from Dr K. Paucker[14]) which was used for the rest of the study. Similar observations have been reported for several other cell types which respond to the anticellular properties of interferon[1–4].

The release of PA by SV3T3 cells is independent of cell density[15]. To determine whether interferon alters this pattern, we grew SV3T3 cells in the presence of interferon for 24 h and measured the PA released into a fresh serum-free harvest fluid (HF) during the next 10–12 h. After collection of the HF, the cells were lysed with Triton X-100, and lysate PA content also determined. Treatment with 50, 100, or 500 NIH reference units interferon ml^{-1} resulted in 37, 54, and 58% reductions, respectively, in the amount of PA released into the HF (significant by Students' t test, $P < 0.005$) (Table 1*a*). In contrast, cell lysate PA activity was not significantly reduced. In two other experiments, up to 1,000 units interferon ml^{-1} did not inhibit PA release any further. Interferon doses higher than 200 units ml^{-1} have resulted in significant decreases in cell lysate PA in some experiments. Direct addition of interferon (up to 500 units ml^{-1}) to the PA assay, or preincubation of control PA samples with interferon for 1 h at 37 °C, did not decrease the assayable PA.

In spite of the relative purity of the interferon used, the participation of residual impurities was considered. Pretreat-

*Interferon was assayed in 3T3 cells by a neutral red dye uptake method patterned after that of Finter[26] using vesicular stomatitis virus as the challenge virus. Units are expressed as reference units based on NIH reference standard G-002-904-51.

†Cells were plated at 5×10^4 cells per 35-mm plastic petri dish (Falcon) in Dulbecco's modification of Eagle's minimal essential medium (Gibco) supplemented with fetal calf serum to a final concentration of 5%. Cells were incubated at 37 °C in a humidified atmosphere of 5% CO_2 in air for 18 h before addition of interferon with medium change. Cell counts were performed in duplicate on cells resuspended by trypsinisation. Cells were counted using a haemocytometer. For preparation of PA samples, cells were grown to a density of 2×10^5–3×10^5 per dish, switched to serum-free medium ± interferon, and the HF collected after an additional 10–12 h of incubation at 37 °C Triton X-100 cell lysates were prepared, and HF and lysate samples assayed for PA activity using ^{125}I-fibrin as the substrate as previously described[27], with slight modifications. The assay mixture contained. 0.1% Triton X-100 in 0.1 M Tris-HCl, pH 8.1, 5–10 μg of purified human plasminogen[28], and HF or lysate sample in 1 0 ml final volume One unit of PA is the amount of enzyme generating enough plasmin to catalyse the hydrolysis of 10% of the total fibrin substrate in 4 h at 37 °C. Plasminogen blanks were subtracted before calculation of the number of units, and data were normalised for cell number or for total protein in Triton X-100 lysates, as determined by the procedure of Lowry *et al.*[29]. Each value is the mean of data from three separate experiments. Each experiment was carried out in duplicate, and each resulting sample assayed two or three times. Data are expressed as % of control values to facilitate comparisons of data derived from separate experiments. Data are shown ± s.e.m.

‡^{3}H-amino acid incorporation was measured at the end of the HF collection using dishes treated in parallel with those used to measure PA. For labelling, cells were washed twice with 37 °C Hank's balanced salt solution (HBSS) containing appropriate doses of interferon or cycloheximide. Cells were labelled for 1 h with 2.5 μCi ^{3}H-L-amino acid mixture (New England Nuclear) in 1 0 ml of HBSS containing interferon or cycloheximide After 1 h the medium was removed, and the cells washed three times with warm HBSS, extracted three times with cold 5% trichloroacetic acid (TCA), and solubilised in 0.6 ml of 0.5 M NaOH. Fetal calf serum (20 μl) was added to duplicate 0.2 ml portions of the solution to serve as unlabelled carrier protein, and the samples neutralised with 4 M HCl. Neutralised samples were precipitated with 2.0 ml of cold TCA and stored at 4 °C overnight. TCA precipitates were collected on Whatman GF/C filters and the filters washed exhaustively with cold 5% TCA, dried, and counted in 10 ml of Omnifluor (NEN) toluene. Data were normalised for protein content of the NaOH solutions as described above and represent mean values ± s.e.m. of duplicate determinations from each of two cultures.

§Cycloheximide (Sigma) was added at the beginning of HF preparation for PA studies.

ment of interferon (100 units ml^{-1}, final concentration) for 1 h at 37 °C with a 1:200 dilution of rabbit anti-mouse interferon serum (titre 4,000, Reference Reagents Branch, NIH) inactivated its antiviral activity, as well as its inhibition of PA release (inhibited by only 13%). In parallel experiments, interferon treated with preimmune serum, or with diluent, retained activity, inhibiting PA release by 46 and 48% respectively. Column void material from an anti-interferon globulin affinity column used for interferon purification[14] did not inhibit PA release even when used at a pre-column equivalent of 10,000 units of interferon ml^{-1}. Heating interferon at 60 °C for 1 h destroyed its effect on PA release, but dialysis at 4 °C for 24 h did not. These properties of mouse interferon are consistent with those reported by Gresser *et al.*[1], and indicate that the observed inhibition of PA release is due to interferon itself.

Interferon does not cause accumulation of PA in SV3T3 cells (Table 1*a*), and at high doses may decrease cellular PA (data not shown). Further, high doses of interferon inhibit protein synthesis in mouse L cells[16]. Thus, the possibility that the effect of interferon on PA release might be due to a generalised inhibition of protein synthesis in SV3T3 cells was considered. Doses of interferon up to 500 units ml^{-1} had no measurable effect on incorporation of ^{3}H-amino acids in SV3T3 cells (Table 1*a*). The total amount of radioactivity (c.p.m.) incorporated was within the linear range for the experimental conditions used. Under similar conditions, cycloheximide (0.1–0.5 μg ml^{-1}) caused a marked, dose-dependent inhibition of ^{3}H-amino acid incorporation (Table 1*b*). Both HF and cell lysate PA activities were also inhibited by cycloheximide. Thus, although inhibition of protein synthesis with cycloheximide causes decreased PA activity in SV3T3 cells, the interferon-mediated inhibition of PA release cannot be explained in terms of a general inhibition of protein synthesis.

Our data suggest that interferon inhibits some aspect of the process of release of PA. Although the mechanism of PA release is not clear, a secretion mechanism has been suggested[17,18]. The firm membrane association of PA (refs 19–21), and its enrichment in plasma membrane fractions of chicken and hamster cells[21], suggest to us that PA may be released through the process of membrane shedding, such as that described for histocompatibility antigens[22,23] and certain membrane-associated glycosyl transferases[24,25]. Thus, inhibition of PA release could be a direct effect of interferon on shedding. Alternatively, since PA release is dependent on cell density in 3T3 cells[15], the interferon effect on SV3T3 cells may be indirect, because of inhibition of cell proliferation. Neither do we yet know whether the interferon effect extends to the release of other cell components. Experiments are in progress to examine these questions.

Different rules govern help for cytotoxic T cells and B cells

RECENT experiments with radiation chimaeras[1,2] indicate that T cells differentiating in an H-2D compatible, but H-2I different, thymic environment are completely unresponsive to vaccinia virus. The explanation favoured[2] for this surprising finding is that participation of helper T cells[3] (TH) is an absolute requirement for the generation of virus-immune cytotoxic T cells (Tc). No response is seen because the TH populations are 'locked in' to recognising the spectrum of H-2I antigens presented on radiation-resistant thymic cells[2]. They cannot, therefore, interact with the Tc precursors which are genetically different in the I region. The result is a total failure of responsiveness. We report here that we have tested this concept further by stimulating acutely tolerised[4,5] T-cell populations in H-2I different, but H-2D compatible virus-infected recipients. Our results indicate that there is apparently no need for participation of TH populations restricted to the H-2I region specificities expressed in the recipient environment. This differs from the situation for TH-B-cell collaboration[4,5], and suggests that help for the Tc response operates directly between T-cell subsets.

An elegant analysis of genetic requirements for T-cell–B-cell collaboration has been made by Sprent[4,5], who used negative selection protocols to remove alloreactive lymphocytes and then tested for TH to sheep red blood cells in irradiated recipients compatible for different regions of the H-2 gene complex. The

SV, Target cells transformed with SV40 virus.

conclusion reached from these studies, and from experiments with chimaeras, is that the macrophages in the stimulator environment and the B cells to be helped must share I-region determinants. Furthermore, as for the Tc response to vaccinia virus[2], differentiating TH precursors only operate in the context of H–2I antigens encountered previously in radiation-resistant thymus[5].

Our intention was to determine whether the same spectrum of interactions applies to the generation of virus-immune cytotoxic T cells. We know that a detectable Tc response only occurs following exposure to virally modified macrophages expressing the H–2K or H–2D phenotype encountered previously in thymus. Does the postulated interaction of TH and Tc[2] cells also require involvement of an infected macrophage presenting, as for T–B collaboration[4,5], the same I-region determinants expressed on radiation-resistant thymus epithelium?

Similar negative selection procedures[4,5] and H–2 haplotype combinations were thus used to analyse the postulated requirement for TH in the Tc response to vaccinia virus. B10.D2 spleen and lymph node populations were first filtered through an irradiated (BALB/c×C57)F$_1$ environment, and thoracic duct lymphocytes were then stimulated with vaccinia virus[6] in B10.A(5R) recipients, which differ from H–2K to I–E. Contrary to expectations, a strong virus-specific Tc response was seen at H–2D^d (Table 2). This cannot be attributed to operation of radiation-resistant TH in the recipients, as the chimaera cells were exposed to virus in the same way but were unresponsive[2]. Stimulation in the absence of other than H–2D end (I–C to –D) homology with the recipient was confirmed in a further experiment (Table 3), where (C3H×BALB/c)F$_1$ T cells were used to minimise the possible involvement of some form of allogeneic effect[7] operating at I–J or I–E (Tables 1 and 2). Furthermore, the addition of lymphocytes capable of mediating allogeneic effects during the sensitisation process (unpublished data) has not, to date, caused any significant enhancement of cytotoxicity in situations where there is a low Tc response[8] to vaccinia virus.

A comparable lack of requirement for I-region homology between T-cell and irradiated recipient was also found for another H–2 haplotype combination (Table 4). However, in one case (Expt 2, Table 4), there was evidence of either residual alloreactivity or generation of a virus-immune cytotoxic T-cell response operating across the H–2 barrier. The second of these possibilities has now been confirmed[9].

Apparently, virus-specific cytotoxic T cells do not need to share I-region genes with the recipient in which they are stimulated, although the presence of the relevant H–2K- or H–2D-encoded antigens is essential (Tables 2 and 4). Thus, if TH cells are involved in the Tc response to vaccinia virus, the mechanism seems to be somewhat different from that defined for TH–B-cell–macrophage interactions, where I-region restriction seems to be absolute when analysed by similar experimental protocols[4,5]. Perhaps helper T cells involved in the virus-immune cytotoxic response are cross-reactive for infected macrophages expressing I-A^d and I-A^b (Tables 2 and 3), or I-A^d and I-A^k (Table 4). The latter is, however, the same combination for which a total failure of the Tc response to vaccinia virus was found in the chimaera experiments[2]. An alternative interpretation is that the postulated interaction between TH and Tc is quite independent of the recipient macrophages and operates essentially between T-cell subsets. Recognition may, for example, be specific for T-cell receptor idiotype[10]. We must also consider the possibility that the influence of I-region genes on the virus-immune Tc response is mediated other than through T-cell help at the time of antigen stimulation, perhaps reflecting

B10.D2 spleen and lymph node cells were inoculated intravenously (2 0–4.0×10^8 cells per mouse) into 10 irradiated (950R, 24 h) (BALB/c×C57BL/6)F$_1$ recipients, and negatively selected T-cells were drained from thoracic duct over the following 18–42 h (ref. 4). Approximately 4.0×10^7 lymphocytes were recovered from the 10 filter mice. These cells were then transferred to two irradiated receipients. Controls were unirradiated mice, or 950R recipients given 6.0×10^7 spleen and lymph node cells. All mice were injected intravenously with 5.0×10^6 plaque-forming units of vaccinia virus at 3 h after cell transfer, and spleen cells were tested for cytotoxicity 6 d later in a standard ^{51}Cr release assay (ref. 11) using vaccinia-infected (vacc.) or normal (N) target cells. All values given are for specific ^{51}Cr release, relative to incubation in medium alone. A strong cytotoxic T-cell response is seen at H–2D^d (5RSV) but not at H–2K^b (MC57G)

Suppression of human T-cell colony formation during pregnancy

THE human fetus, as a natural allograft, escapes destruction by the maternal immune system. As a possible mechanism, Alexander[1] proposed a rapid shedding of transplantation antigens by embryonic cells, resulting in a blindfolding of the otherwise fully functional maternal immune system. Other investigators have reported a suppressive activity of lymphoid cells from human cord blood on the proliferation of maternal lymphocytes[2,3]. Suppressor T cells are induced by α-fetoprotein in mice[4], and the elevated levels of α-fetoprotein during pregnancy have been shown to exert an immunosuppressive influence in mice[5,6] and in man[7]. Olding[8] demonstrated a soluble factor from mitogen stimulated lymphoid cells of human newborns suppressing the proliferation of maternal lymphocytes. These observations point out that the embryo might protect itself by release of soluble factors, acting either themselves as lymphocyte suppressive agents, and/or by the induction of suppressor cells. However, no direct evidence has so far been presented to show the presence and action of T-cell suppressor cells in the immune system of pregnant women. Such an experiment would have to use components of the immune system of pregnant women solely, and therein demonstrate an immune suppression as compared to non-pregnant individuals. We present here results indicating that the ability of T cells from pregnant women to proliferate in soft agar cultures is strongly inhibited, regardless of the source of the serum being used in the assay, thus pointing rather to a cell-mediated suppressor mechanism.

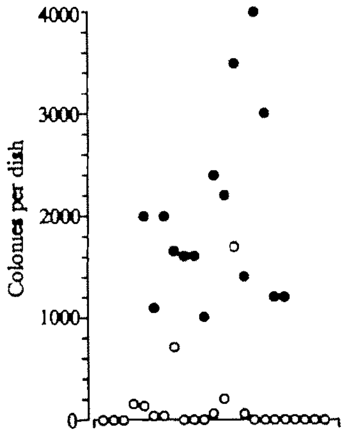

Fig. 1 3×10^6 lymphocytes were incubated overnight with PHA (4 μg ml^{-1}) in 5 ml RPMI 1640 containing 15% autologous serum. After 15–18 h, 2×10^5 cells were seeded into a RPMI-soft agar medium, containing the same serum, and incubated for 5 d at 37 °C and 7% CO_2. The number of T-cell colonies from non-pregnant donors (●) ranged from 1,000 to 4,000. The pregnant women (○) had a strongly impaired colony formation

Twenty healthy pregnant women aged 20–34 yr and between the 10th and 41st weeks of gestation, gave their informed consent to *in vitro* analysis of cellular immune functions. Venous blood was collected in syringes containing RPMI 1640 and heparin, and the lymphoid cells were isolated by the Ficoll–Hypaque technique[9].

Phytohaemagglutinin A(PHA) and concanavalin A(ConA) stimulation *in vitro* was performed according to Cunningham-Rundles[10]. T cell-quantitation[11] was performed in each case, as well as the T-cell colony test (TCC-test[12,13]). For the TCC-test, purified PHA (Wellcome, catalogue no. HA 17) instead of PHA-M was used. Thus we could obtain 1,000–4,000 colonies per dish, seeding 2×10^5 lymphocytes into the dishes, from healthy non-pregnant donors. Of the cells obtained from the colonies, 80–90% formed E-rosettes, characteristic for T cells.

Table 1 shows the T-cell proportions and the lectin stimulation test in the pregnant women compared with a normal population. No significant change in the T-cell proportions and no marked inhibition of lectin stimulation was seen in the pregnant women. Figure 1 shows the TCC-test in the pregnant women, compared with the activity in 15 healthy non-pregnant donors. In 61% of the cases the pregnant women were completely unable to form colonies. In 30% of the cases, the colony forming activity was reduced to less than 5% of the activity in the control donors, the normal mean value being 2,000, (standard derivation, s_x, 900) per dish. If the cells from the pregnant women were incubated in a pooled human serum in which the control cells gave normal colony counts, no improvement of the colony forming activity could be observed (Fig. 2*a*).

Lymphocytes of healthy donors cultivated as an ABO compatible system in the presence of serum from the pregnant women (Fig. 2*b*) gave normal colony counts. Hence we assume that the factor depressing the clonal proliferation of T-cells in

Table 1 T-cell proportions and lectin stimulation test in pregnant and non-pregnant women

ConA stimulation (c.p.m.)	11,122	5,075	18,620	11,206

5×10^4 lymphocytes were incubated in 150 μl RPMI 1640 with 15% pooled human serum and 60 μg ml^{-1} ConA or 20 μg ml^{-1} PHA-P. After 96 h at 37 °C, 0.2 μCi ^{3}H-TdR (6.4 Ci mmol^{-1}) was added. After 24 h the cultures were collected using a multiple sample harvester, and counted in a scintillation counter.

0028-0836/78/0276—0831$01.00

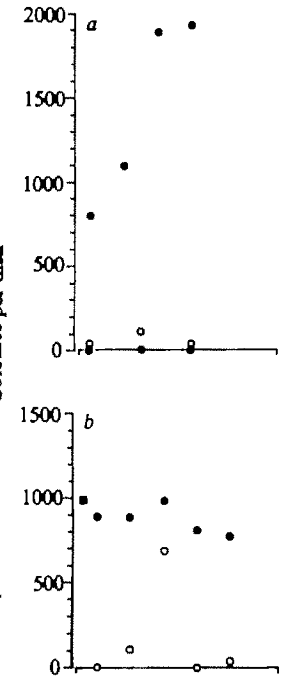

Fig. 2 *a*, T-cell colonies from non-pregnant donors in pooled serum (●), from pregnant women, incubated in the same serum pool (◐) and in autologous serum (○). Substitution of the serum from the pregnant women by normal serum caused no improvement of the colony formation. *b*, T-cell colony count from one non-pregnant cell donor after incubation in autologous serum (■), and in serum of ABO-compatible pregnant women (●). The T-cell colony formation from the same pregnant women in their own serum served as a control (○) No significant depression of normal T-cell colony formation was seen in serum from pregnant women.

this system is cellular, rather than humoral. The presence of a factor in the blood of pregnant women able to suppress the proliferation of T lymphocytes may, considering the report of Olding[8], reflect the ability of the fetus to defend itself against the maternal immune system.

The failure of lectin stimulation analysis to show any significant change in the pregnant women indicates that the TCC-test has a much higher sensitivity in detecting factors inhibiting T-cell proliferation.

The kinetics of the suppressor phenomenon described here, are now being investigated. Preliminary results have shown that the immune depression described above is seen as early as 6–10 weeks after onset of pregnancy, and is abolished between the 35th week of gestation and the sixth week after delivery.

Catecholamines of supposed inhibitory hypophysiotrophic function suppress action potentials in prolactin cells

THE anterior lobe of the pituitary gland has a uniquely important function in the endocrine system, for its six different endocrine cell types constitute the major endocrine link between the brain and the rest of the body. The brain is known to control this remarkable composite gland through specialised neurones lodged in the hypothalamus that elaborate and release hypophysiotrophic factors; these are carried by the hypophysial portal blood vessels to act on their respective target cells through stimulation or inhibition of secretory activity[1,2]. However, the way in which these factors act at the cellular level is uncertain, although discharge of the various hormones of the anterior pituitary lobe is known to show calcium dependence and can be induced by depolarising concentrations of potassium[3–5]; this pattern of endocrine behaviour was first recognised in adrenal chromaffin cells[6] and is consistent with the calcium hypothesis of stimulus–secretion coupling[7], which, in chromaffin and some other cells, is associated with electrical excitability[8–13]. It is therefore of much interest that normal gland cells of the anterior pituitary lobe[14,15], like their neoplastic counterparts[16–18], have been found to generate action potentials with a calcium component indicative of influx of calcium ions; furthermore, the frequency of action potentials can be increased in some of these cells by thyrotropin releasing factor (TRF)[14]. This has prompted the suggestion that it may be through the initiation or modulation of action potentials that the brain, through the hypophysiotrophic factors, regulates secretion in the anterior pituitary[14]. However, the evidence which supports this scheme is scanty. The experiments with TRF were carried out on disaggregated anterior pituitary lobes of rats which contain six different endocrine cells, and the method did not allow identification of the cells stimulated by TRF; thus, it could only be supposed that they were the appropriate target cells[14]. Clearly, it is essential that evidence be obtained on the electrical behaviour of normal anterior lobe cells of defined type, and the effects thereon of specific and relevant hypophysiotrophic factors. Here we report that normal prolactin cells generate spontaneous action potentials which are suppressed by hypothalmic catecholamines known to inhibit prolactin secretion.

In mammals, the intermingling of the various endocrine cells in the anterior lobe of the pituitary impedes the correlation of electrical behaviour with cell type. However, in teleost fishes, the various anterior pituitary cells are segregated by functional type into distinct regions. In particular, the prolactin cells, which are most appropriate for our purpose, are grouped in a distinct lobe (rostral pars distalis) which is easy to identify and excise[19–21]. Moreover, teleostean prolactin cells are a suitable model as they behave like their mammalian counterparts in important respects: their secretory activity *in vivo* is subject to inhibitory hypothalamic control apparently exerted by hypophysiotrophic catecholamines; and *in vitro*, when this control is absent, secretion increases greatly but can be restrained by catecholamines[19–22]. It follows that if action potentials are intimately involved in regulating secretion, then prolactin cells should show spontaneous action potential activity *in vitro* and this should be inhibited by catecholamines. Our experiments confirm these expectations and demonstrate that the action

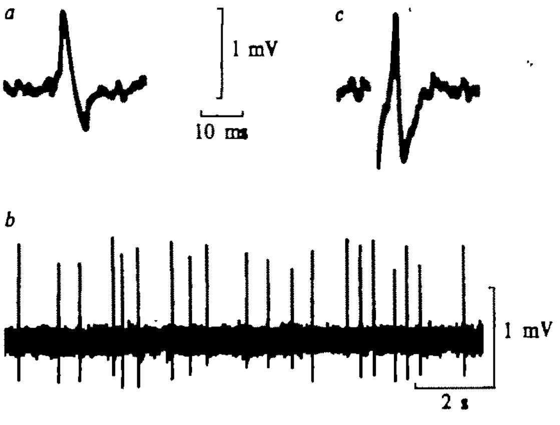

Fig. 1 Action potentials in prolactin cells. *a* and *b*, Spontaneous action potentials recorded extracellularly (with a microsuction electrode[14]) at fast and slow sweep speeds from the same cell, to demonstrate the shape of individual action potentials (*a*) and pattern of spontaneous activity (*b*). *c*, Evoked action potential from a second cell elicited by an outward (depolarising) current pulse of 3.5 nA passed through the extracellular recording electrode. The frequency of spontaneous action potentials in this cell was low (0.08 Hz). The recording solution contained (in mM) NaCl, 183; KCl, 5; $CaCl_2$, 2; glucose, 5.5; HEPES, 5 (*p*H 7.1) with 1 mg ml^{-1} bovine serum albumin (BSA). Experiments were done at 17–20 °C. Top calibrations apply to both *a* and *c*. The cells used for electrophysiological study were prolactin cells in primary culture obtained as follows. Pituitary glands were removed immediately after decapitating live, mature (about 30 cm) *Alosa pseudoharengus* (10–20 specimens per experiment). The anterior one-half to two-thirds of rostral pars distalis was excised from each, pooled and mechanically disaggregated by shearing with siliconised Pasteur pipettes with flame-polished tips of inner diameter ≤1 mm. Disaggregation medium was 3 ml Ham's F-10 (Gibco) supplemented with 15% horse serum, 2.5% fetal calf serum, 35 mM NaCl, 100 U ml^{-1} penicillin and 100 μg ml^{-1} streptomycin, and saturated with 5% CO_2 – 95% O_2 at room temperature. Dispersed cells were centrifuged at 100*g* for 8 min and the pellet resuspended in 2 ml recording solution (see above). To remove debris, suspended cells were layered on 5 ml recording solution containing 4% BSA and spun down at 100*g* for 8 min. Sedimented cells were resuspended in supplemented Ham's F-10 and placed in Falcon dishes (35 mm) coated with poly-L-lysine (Sigma type V). Dishes, each containing cells from two pituitaries in 2 ml medium, were maintained at room temperature and generally used for experiment within 10 d.

potentials involve a calcium component which probably provides a stimulus to secretion.

The fish used was the alewife (*Alosa pseudoharengus*); the pituitary gland of this species has a large and clearly defined rostral pars distalis shown to consist essentially of a mass of large prolactin cells containing prominent secretory granules, the only other endocrine cells present being small ACTH cells arranged in a thin layer along the posterior border[33]. We avoided these ACTH cells by using only the anterior one-half to two-thirds of the rostral pars distalis, which we disaggregated and maintained in culture (see legend to Fig. 1). The dispersed cells were observed under phase contrast at high magnification (×800) and records were obtained from those whose large size and granular content indicated them to be prolactin cells.

Most of the cells monitored showed spontaneous action potential activity (Fig. 1*a*). Of >100 spontaneously active cells, almost all fired at random intervals (Fig. 1*b*), but a few fired in a bursting pattern. Action potentials could also be induced, or their frequency increased, by outward (depolarising) current pulses passed through the electrode (Fig. 1*c*). When driven by current pulses, cells sometimes fired at frequencies in excess of 25 Hz. The average rate of spontaneous discharge, however, was 1 Hz (0.8 ± 0.1 Hz, mean ± s.e.m., $n = 23$, records selected to avoid influences of drugs).

Tetrodotoxin (TTX) reversibly depressed the amplitude of the action potentials (Fig. 2*a*, *b*), indicating that they result mainly from an increase in membrane conductance to sodium ions[34]. However, a calcium component was also present, as blockade of potential-dependent potassium conductance by the addition of tetraethylammonium (TEA) to the TTX-containing solution resulted in large regenerative potentials that were reversibly suppressed by replacing calcium in the bathing solution with manganese (Fig. 2*c*, *d*). The action potentials thus involve inward currents of both sodium and calcium ions (see refs 35, 36).

The catecholamines dopamine and noradrenaline, which are the principal factors in hypothalamic extracts capable of inhibiting secretion from isolated prolactin cells[37,39], had inhibitory effects on spontaneously firing prolactin cells and either slowed or arrested the discharge of action potentials. Arrest was the most common response when these substances were used in a concentration of 10^{-6} M. It occurred within a few seconds and often persisted for many seconds after the catecholamine had been withdrawn (Fig. 3*a*, *b*). We have not attempted to determine minimal effective concentrations but have noted that concentrations as low as 10^{-8} M can slow impulse discharge (Fig. 3*c*). When discharge persisted, albeit at reduced frequency, during exposure to dopamine or noradrenaline, the amplitude of the action potentials was unaltered. The catecholamines therefore seem to inhibit the mechanism which initiates the action potentials (the 'generator potential') and not the potential-dependent conductances that underlie these spikes.

Our experiments thus provide new information on the control of anterior pituitary secretion: (1) They indicate that normal prolactin cells, in conditions in which they secrete spontaneously, have spontaneous action potentials; (2) they demonstrate that these action potentials, although mediated mainly by sodium, involve inward calcium movement which, from evidence on many secretory systems[7,40] including prolactin and other anterior pituitary cells[3–5], should provide a stimulus to secretion; (3) they show that putative inhibitory hypophysiotrophic factors reduce this electrical activity. Together, these findings strengthen the hypothesis that hypophysiotrophic factors control secretion in the anterior pituitary gland by

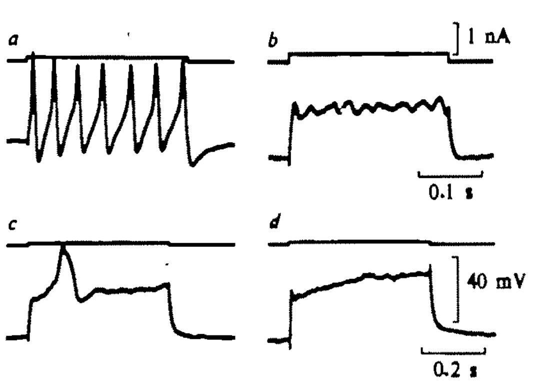

Fig. 2 Ionic basis of action potentials in prolactin cells. Intracellular recordings from two different cells showing the effect of TTX (*a*, *b*) and of replacement of Ca^{2+} by Mn^{2+} (*c*, *d*) *a*, Repetitive action potentials evoked by a single outward (depolarising) current pulse passed through the recording electrode. *b*, Response of the same cell during exposure to TTX (2×10^{-6} M) applied by a delivery pipette[14]. The action potentials are virtually abolished *c*, Response of a second cell to a depolarising pulse while bathed in a solution containing TTX (5×10^{-6} M) with the further addition of TEA (10 mM). A prominent regenerative potential is evident. *d*, Response of the same cell when perfused (by drug delivery pipette) with the same medium except that Ca^{2+} was replaced by Mn^{2+}. The regenerative response is abolished. Top trace in all records indicates current passed and zero level of membrane potential. Calibrations for current and potential apply to all four sets of records. Intracellular recording was done by conventional techniques using glass microelectrodes filled with 4M potassium acetate, *p*H 7.1, with resistance 60–100 MΩ. A bridge circuit was used for passing current. To facilitate intracellular recording the Ca^{2+} concentrations were increased to 10 mM throughout except in *d*, where it was replaced by 10 mM Mn^{2+}.

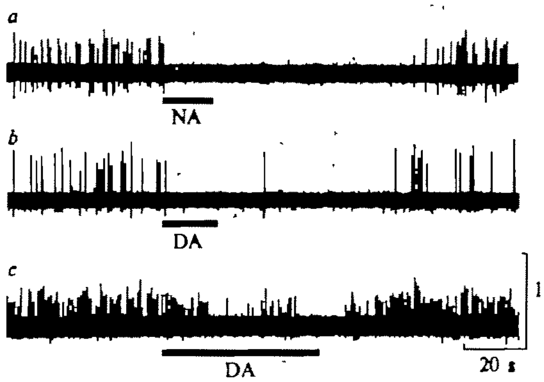

Fig. 3 Inhibition of spontaneous action potentials in prolactin cells by catecholamines. Catecholamines (in recording solution) were applied to the cells by drug delivery pipette for periods indicated by bars under the records. *a*, Arrest of spontaneous discharge by noradrenaline (10^{-6} M NA). *b*, Similar effect, in a second cell, produced by dopamine (10^{-6} M DA) *c*, Slowing of spontaneous discharge, in a third cell, by a lower concentration of dopamine (10^{-8} M). Similar responses were obtained in 32 of 34 cells tested.

affecting action potential activity in their target cells. Finally, in common with others[19–21], we consider that the teleost pituitary, because of the segregation of cell types, offers unique advantages for the study of hypophysial function.

Neurone-specific enolase is a molecular marker for peripheral and central neuroendocrine cells

NEURONE-SPECIFIC ENOLASE (NSE) is the most acidic brain isoenzyme of the glycolytic enzyme enolase (EC4.2.1.11) and has been shown to be homologous to the 14-3-2 protein isolated from bovine brain by Moore[1–3]. Whereas NSE is exclusively localised in neurones in mammalian nervous tissue[4,5], another brain enolase isoenzyme termed non-neuronal enolase (NNE) is localised in glial elements[5]. As NSE and NNE are structurally, functionally and immunologically distinct isoenzymes that represent separate gene products[6,7], they are useful markers for cell classes in the nervous system. Although NNE is probably identical to liver enolase, NSE has to date been considered to be localised in neurones. We now report that NSE is also present in peripheral and central neuroendocrine cells, also termed amine precursor uptake and decarboxylation (APUD) cells[8–10]. Immunocytochemistry using the unlabelled antibody enzyme method of Sternberger[11] demonstrates that APUD cells in both laboratory rat and rhesus monkey (*Macacca mulatta*) stain positively with NSE antiserum. Using a sensitive radioimmunoassay (RIA) for NSE, it is possible to confirm their localisation in adrenal gland and to support the finding in other APUD-cell-containing tissues in rat, monkey and man. The results in human tissues suggest that the immunocytochemical localisation in rat and monkey will be valid for man and prove useful in the study of human diseases involving the APUD cell class.

Antisera to purified neurone-specific enolase isolated from rat (NSE-R) and human (NSE-H) brain were prepared in New Zealand white rabbits as previously described[12]. The sera were not reactive with NNE. Antiserum to NSE-H reacts identically with monkey and human brain extracts, indicating that this serum cross-reacts quantitatively with monkey NSE (NSE-M). Animals were anaesthetised and perfused through the aorta first with normal saline and then with 4% paraformaldehyde–1% glutaraldehyde–0.2% picric acid in 0.1 M sodium acetate buffer, *p*H 6.0, with 1.5% sucrose. Tissues were fixed for 2–6 h and washed overnight. Monkey tissue was cut into 10–25 μm thick sections on a vibratome or cryostat; rat tissue was imbedded in polyester wax[13] and cut at a thickness of 4–8 μm. The rest of the staining proceeded according to the unlabelled antibody enzyme method[11]. Preimmune serum and NSE-absorbed serum served as controls.

Stained sections revealed that NSE antiserum reacts specifically and uniformly with the APUD series of neuroendocrine cells[8–10] in each gland or tissue (Table 1). Both rat and rhesus monkey gave identical results. In pancreas, the cells of the islets of Langerhans exhibit positive staining, in contrast to the surrounding exocrine acinar and epithelial cells, which do not stain (Fig. 1*a*). All islet cells stain positively, although there is some variation in intensity among cells. NSE staining in the adrenal gland (Fig. 1*b*) clearly delineates the positive chromaffin cells of the medulla from the non-staining cortex. NSE-positive cells in the thyroid (Fig. 1*c*) are compatible in position and number with parafollicular calcitonin (CT) cells, whereas the thyroid follicular cells are NSE negative. Likewise, pinealocytes in the pineal and cells of the pituitary, especially those of the pars intermedia, all stained for NSE. Interstitial and epithelial cells remained unstained. In the hypothalamus, neuroendocrine cells contain NSE as do all neurones in the central and peripheral nervous system.

To test the hypothesis that neuroendocrine cells contain NSE, quantitation of NSE in rat, monkey and human tissues was accomplished by RIA. Previous work has demonstrated that NSE is a major soluble protein constituent of brain[12]. The levels of NSE in rat, monkey and human whole brain extracts range from 12,500 to 16,000 ng NSE per mg soluble protein (Table 1), representing 1 25–1.6% of the total soluble protein in brain.

Table 1 Neurone-specific enolase levels in various tissues of rat, rhesus monkey and man

Tissue	NSE (ng per mg protein) Rat	 Monkey	 Human	NSE Localisation by immunocytochemistry
Brain	12,500 ± 105	14,000	16,000	Neurones including central neuroendocrine cells of the hypothalamus
Pineal	2,650 ± 400	7,700	8,060	Pinealocytes
Adrenal	250 ± 11	—	—	
Cortex	—	50	100	None
Medulla	—	680	940	Chromaffin cells
Pituitary	2,000	—	600	
Anterior lobe	900	1,180	—	Anterior pituitary cells
Posterior lobe	3,400	2,870	—	Pars intermedia cells and endings of the hypothalamo–hypophysial system
Pancreas	18 ± 1.5	49	—	Islet cells
Thyroid	150	—	250	Presumed CT cells
Muscle	9	<1	—	None
Liver	4	1	3	None

Rat tissues such as pineal, adrenal, pituitary and thyroid represent pools of 5–20 animals. All tissue was homogenised in 20 mM Tris-PO_4, 2 mM $MgSO_4$, *p*H 7.4. The 100,000*g* supernatant was obtained. A double-antibody radioimmunoassay was developed for NSE from rat, monkey and human. Antiserum raised in rabbits to purified NSE-H was used in the monkey and human tissue assays and antiserum to purified NSE-R for the rat tissue. Each assay contained 4,000 d.p.m. of tritiated antigen (20-30 ng), prepared as previously described[12], antiserum (1:40,000 dilution for anti-NSE-R and 1:1,000 for anti-NSE-H) and the sample to be measured. The assay volume was 0.5 ml and all solutions were diluted in the assay buffer (0.15 M Tris-PO_4, *p*H 7.4, 2 mM $MgSO_4$ and 1% bovine serum albumin). The samples were incubated at 4 °C for 16 h followed by the addition of 250 μl of a 2 mg ml^{-1} solution of solid-phase anti-rabbit IgG (Bio-Rad Immunogarb). The second antibody incubation proceeded for 2 h at room temperature followed by washing and counting of the beads. Standard curves for each assay were linear over 2–100 ng. No cross-reactivity was observed with NNE (1 μg). S.e.m. are presented when four or more groups of animals were assayed.

Liver and muscle have very low levels of NSE that probably reflect the contribution of peripheral nerve processes present in these tissues. In contrast, significant amounts of NSE are present in the glandular tissues listed in Table 1, including levels in the pineal that approach those of brain. In contrast to pineal and pituitary, pancreas and thyroid have fewer APUD cells but still have levels of NSE that are clearly higher than those of liver and muscle. Assay of NSE in the adrenal medulla and cortex directly confirms the immunocytochemical localisation (Table 1). NSE levels by RIA are 10-fold higher in the medulla than in the cortex, consistent with the positive NSE staining of adrenal medullary chromaffin cells and non-staining of cortical cells.

The striking and consistent staining of APUD cells in rat and monkey by NSE antiserum coupled with quantitative evidence that in rat, monkey and man this represents actual NSE content makes NSE a unique, generalised molecular marker for these neurone-like cells. Whereas previous classification of APUD cells has had to rely on staining and physiological properties which occasionally proved difficult to document for a given cell class[8–10], the presence of NSE provides a simple and useful method for identifying members of this group. In cultured neuroblastoma cells (transformed cells of the APUD cell series), the levels of NSE correlate with the degree of differentiation induced by pharmacological manipulation[14]. NSE may, therefore, prove useful in the diagnosis and staging of tumours of APUD cells (apudomas) in humans.

The presence of a neuronal antigen in neuroendocrine cells further contributes to studies of the neurone-like character of these cells[10]. Not only do cells of the APUD classification have secretory properties similar to those of a neurone and, in most cases, a known associated peptide, they also exhibit excitable membrane properties in tissue culture[15]. As NSE has distinct

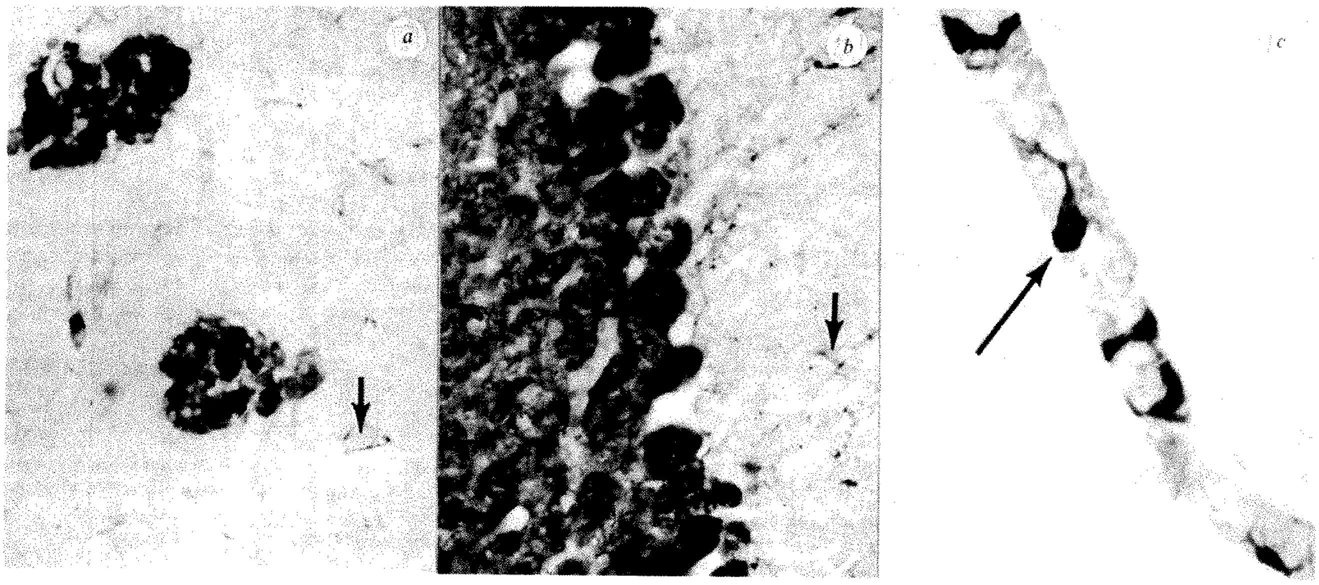

Fig. 1 Photomicrographs of rhesus monkey pancreas, adrenal and thyroid stained for NSE by the unlabelled antibody enzyme method. In each case, sections were incubated for 24 h with 1:1,000 anti-NSE antiserum. Controls carried out with preimmune and preabsorbed serum at 1:1,000 dilution showed no staining. *a*, 15-μm cryostat section of pancreas showing NSE staining of cells in islets of Langerhans. Some nerve processes are visible in the surrounding exocrine tissue (vertical arrow) but no epithelial or exocrine cells stain. ×130. *b*, 20-μm vibratome section of adrenal at the cortico–medullary border. Medullary chromaffin cells are stained and only occasional fragments of nerve processes stain in the cortex, but no cortical cells (vertical arrow). ×130. *c*, 15-μm cryostat section of thyroid showing the wall of one follicle with several NSE-positive cells (one is indicated by oblique arrow) amidst non-staining follicular cells. These positive cells are presumed CT cells. ×860.

structural and functional properties that may be an adaptation to the neuronal cytoplasm[7], the presence of NSE may be related to the neurone-like function of APUD cells. Alternatively, NSE may reflect the neural crest and neuroectodermal origin of these cells during development. Whatever the reasons for its presence, the availability of a generalised molecular marker for both peripheral and central neuroendocrine cells will be useful in studies of cellular differentiation both *in vivo* and in tissue culture. Finally, the possibility of simplifying and enlarging the APUD cell classification may settle some of the controversy concerning peptide-secreting tumours and their classification in man.

We thank Drs Frederick K. Goodwin, Irwin J. Kopin and Ludwig Sternberger for their support during this work.

Slow synaptic excitation mediated by serotonin in Auerbach's plexus

THE application of low concentrations of substance P to guinea-pig myenteric neurones has been reported by Katayama and North to produce depolarisation associated with an increase in input resistance and augmented excitability[1]. On this basis, they suggested that substance P may be involved in the production of the slow excitatory postsynaptic potential (e.p.s.p.) which can be evoked in myenteric neurones by electrical stimulation of the interganglionic connectives[2]. In this report, we show that application of serotonin (5-HT) mimics the slow e.p.s.p., and present several lines of evidence which suggest that 5-HT is a more likely candidate for the neurotransmitter of the slow e.p.s.p.

We used conventional methods to record intracellular electrical activity in myenteric ganglion cells of guinea-pig small intestine and to apply 5-HT iontophoretically to these cells[2]. Thirty-one ganglion cells were studied during electrode impalements which were maintained for 2–8 h. The effects of each drug and altered ionic composition of the bathing medium were always reversed by washing in normal Krebs solution, and all treatments were retested from two to four times on each cell.

The somal membranes of the 31 cells were relatively inexcitable in the absence of fibre tract stimulation and exogenous 5-HT. The cells would either not discharge in response to depolarising current pulses injected through the recording microelectrode or would fire only one, sometimes two, spikes only at the onset of the current pulse. When these spikes occurred, they were followed by prolonged (2–15 s) hyperpolarising after-potentials during which input resistance of the cells was decreased. These cells had resting potentials of −58 to −60 mV. Electrical stimulation of fibre tracts which entered the ganglia increased the excitability of the somal membranes of these cells. Increased excitability was reflected by maintained discharge of spikes that continued for 5–42 s after cessation of fibre tract stimulation (Fig. 1*a*), and by an increase in the number of spikes elicited by intracellular injection of a depolarising current pulse (Fig. 1*b*). In contrast to the relative inexcitability before fibre tract stimulation, immediately after and during such stimulation, spike discharge occurred throughout the application of depolarising pulses, and the frequency of spike discharge increased in direct proportion to the intensity of the injected current.

The increased excitability following fibre tract stimulation was associated with depolarisation of the cell membrane (−8 to −20 mV) and an increase in input resistance which persisted for 1–2 min after the end of the stimulation (Fig. 1*c*). During the excited state, the somal membranes discharged spikes at the offset of hyperpolarising current pulses, and these spikes as well as the continuous discharge were eliminated by hyperpolarisation of the membrane with steady hyperpolarising current injected through the recording micropipette (Fig. 1*c*). The increase in input resistance was not due to rectification because it still occurred when the depolarisation of the response was reversed by injection of hyperpolarising current.

The following observations indicated that the excitatory response to fibre tract stimulation resulted from release of a chemical substance. The response was (1) blocked in Krebs solution containing 16 mM Mg^{2+} and 1.25 mM Ca^{2+}; (2) blocked in HEPES buffered Krebs solution containing 1 mM

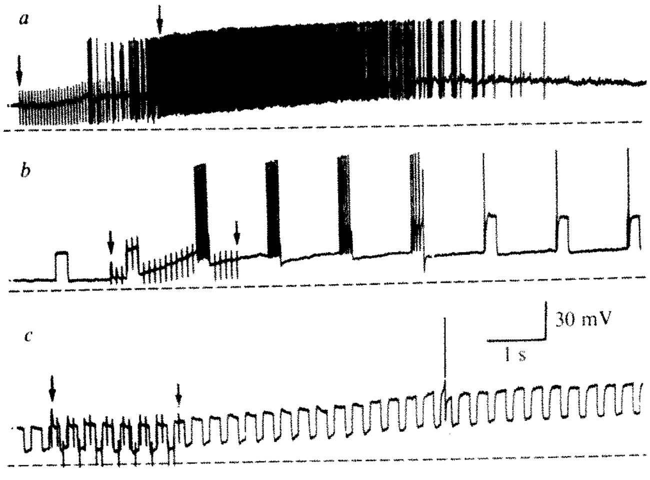

Fig. 1 Effects of fibre tract stimulation on guinea-pig myenteric neurones. *a*, Slow e.p.s.p. and spike discharge elicited by electrical stimulation of the interganglionic fibre tract (arrows indicate onset and offset of stimulus pulse train). *b*, electrical stimulation of fibre tract caused an increase in excitability as indicated by spike discharge throughout constant current depolarising pulses (0.4 nA). *c*, Fibre tract stimulation during repetitive injection of constant current hyperpolarising pulses (0.3 nA). Increased input resistance was reflected by increased amplitude of electrotonic potentials following fibre tract stimulation. Membrane potential was held 18 mV greater than resting potential by steady hyperpolarising current to prevent spikes at the offset of current pulses. One such spike still occurred.

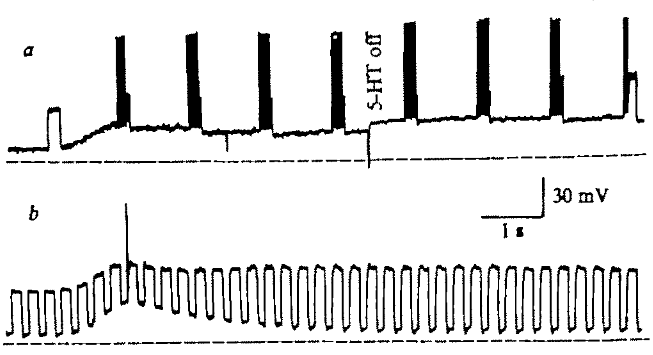

Fig. 2 Effects of microiontophoresis of 5-HT onto a guinea-pig myenteric neurone. *a*, Iontophoresis of 5-HT increased excitability and the cell discharged spikes throughout constant current depolarising pulses (4 5 nA). Iontophoretic current (300 nA) was turned on 9.5 s before the start of the record. Offset of the iontophoretic current is indicated. *b*, iontophoresis of 5-HT during repetitive injection of constant current hyperpolarising pulses (4.5 nA). Increased input resistance was reflected by increased amplitude of electrotonic potentials during 5-HT iontophoresis. The membrane potential was held 20 mV greater than the resting potential by steady hyperpolarising current to prevent spikes at the offset of current pulses. One such spike still occurred. Iontophoretic current was turned on 4.5 s before the start of the record and remained on throughout. Separation between the tip of iontophoretic pipette and the recording electrode was ~10 μm. The tip of the iontophoretic pipette did not penetrate the periganglionic sheath.

Mn^+; (3) enhanced in Krebs solution containing 7.5 mM Ca^{2+}. The response was unaffected by 6 μM nicotine, 10 μM prostigmine, 140 μM (+)tubocurarine and 140 μM atropine which suggested that the chemical substance was not acetylcholine.

Microiontophoretic application of 5-HT mimicked the excitatory response to fibre tract stimulation (Fig. 2*a*, *b*). When 5-HT was iontophoresed onto the cells, the membrane potential depolarised (–6 to –20 mV), input resistance increased, the cells discharged spikes throughout a depolarising current pulse, and frequency of spike discharge during a current pulse was directly related to the intensity of the depolarising current. The alterations of membrane potential and input resistance required 1–3 min to return to control levels after removal of the iontophoretic current. Iontophoretic current passed through control pipettes containing 3 M NaCl had no effect on the neurones. The 5-HT solution in the iontophoretic pipettes had a *p*H of 3–4; however, it is unlikely that the action of 5-HT was due to *p*H change because the 5-HT was ejected into a relatively large volume buffered at *p*H 7.4.

The excitatory responses to both fibre tract stimulation and exogenous 5-HT were reversibly blocked by 30 μM methysergide, a 5-HT antagonist. The responses to both nerve stimulation and iontophoresed 5-HT were reversibly blocked after addition of 5-HT (1–2.5 μM) to the perfusion solution. The excitatory response to iontophoresed 5-HT was unaffected by the presence of 16 mM Mg^{2+} and 1 mM Mn^{2+} in the perfusion solution.

The slow synaptic potential in myenteric neurones is associated with reduction of postspike hyperpolarising potentials and a dramatic increase in the excitability of the somal membrane. Earlier workers referred to this population of myenteric neurones, which generates prolonged hyperpolarising after-potentials, as either type II cells[3] or AH cells[4], and suggested that they were sensory neurones, because no synaptic input could be demonstrated. This seems unlikely in view of the present findings.

The following observations by others have implicated 5-HT as a neurotransmitter within the myenteric plexus. (1) Some of the 5-HT effects on contractile activity of intestinal musculature *in vitro* do not occur after neural blockade with tetrodotoxin[5,6]. (2) Extracellular recording from myenteric neurones shows an increase in the rate of spike discharge in the presence of 5-HT[7]. (3) Application of 5-HT increases the rate of release of acetylcholine from myenteric neurones[8]. (4) Serotonin, tryptophan hydroxylase and serotonin binding protein are present within myenteric neurones[9–12]. (5) Myenteric neurones synthesise 5-HT from its precursor, tryptophan[12]. (6) Tetrodotoxin-sensitive release of tritium-labelled 5-HT and its binding protein occur during transmural electrical stimulation of intestinal segments *in vitro*[13]. (7) Myenteric neurones possess a high-affinity uptake mechanism for 5-HT[14,15].

When the present results are considered with previous evidence, it becomes apparent that most of the criteria for establishing 5-HT as a neurotransmitter in Auerbach's plexus have been fulfilled: serotonin is synthesised and released by myenteric neurones; microiontophoresis of 5-HT mimics the action of the natural transmitter; actions of both the natural transmitter and 5-HT are blocked by the 5-HT antagonist, methysergide; tachyphylaxis occurs in excess 5-HT; inactivation mechanisms in the form of specific uptake of 5-HT exist in the myenteric plexus.

Our observations together with those of Katayama and North[1] suggest that a functional relationship between substance P and 5-HT may exist, because substance P is also present within the myenteric plexus. It is noteworthy in this respect that in the brain 5-HT and substance P co-exist within synaptic vesicles[16].

Neurotransmitters decrease the calcium component of sensory neurone action potentials

RELEASE of neurotransmitters from presynaptic axon terminals requires the influx of Ca^{2+} ions during the nerve terminal action potential[1]. Action potentials recorded in some neurone cell bodies exhibit a relatively large Ca^{2+} component, and it has been suggested that these soma Ca^{2+} spikes may provide a model for Ca^{2+} influx across the less accessible nerve terminal membrane[2]. Recent data support the usefulness of this model. Serotonin (5-hydroxytryptamine, 5-HT) increases transmitter output at certain habituated sensory nerve-motoneurone synapses in the abdominal ganglion of *Aplysia* and it also prolongs the Ca^{2+} spike recorded in the sensory neurone cell body[3]. Enkephalin reduces the stimulated release

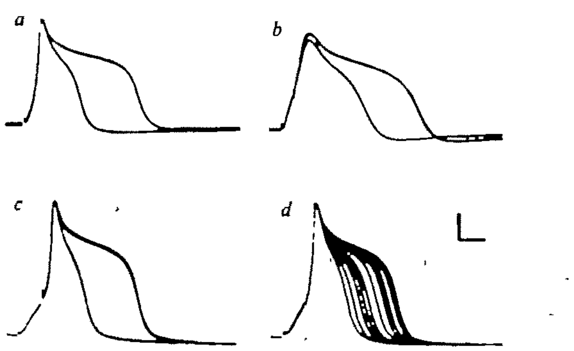

Fig. 1 The effect of *a*, 10^{-5} M 5-HT; *b*, 10^{-4} M GABA; *c,d*, 10^{-4} M NA on the DRG neurone soma action potential. The two successive sweeps show the spike before (longer duration) and after drug application Return to control duration shown in *d* with 10-s interval between sweeps. Calibration, 20 mV and 2 ms.

of substance P by adult cat trigeminal neurones[4] and by cultured embryonic chick dorsal root ganglion (DRG) neurones[5], and it decreases the quantal content of excitatory postsynaptic potentials (e.p.s.ps, transmitter unknown) evoked in cultured rat spinal cord neurones by co-cultured DRG cells[6]. This peptide also decreases the duration and magnitude of the Ca^{2+} component of the DRG soma spike[5]. With the thought that modulation of Ca^{2+} currents may be a general correlate of presynaptic inhibition, we have studied the effect of several putative neurotransmitters on the soma spike of cultured chick sensory neurones, and report here that they decrease the calcium component of cell body action potentials.

Lumbar and thoracic DRG were dissected from 9–11-d-old chick embryos, incubated for 20 min in 0.01% collagenase, mechanically dissociated into single cells by trituration through a Pasteur pipette, and plated in 35-mm collagen-coated Falcon tissue culture dishes. Cells were maintained in Eagle's minimum essential medium supplemented with 10% horse serum, 5% chick embryo extract, 2 mM glutamine, 22 mM glucose, 5 μg ml^{-1} streptomycin, 50 IU ml^{-1} penicillin and 1.0 μg ml^{-1} of 2.5S nerve growth factor (NGF) (purified from mouse salivary gland). Non-neuronal background cell growth was halted at confluence by γ-irradiation with ^{60}Co.

Using previously described techniques[7], intracellular recordings were made from DRG neurones which had been in culture for more than one week. The cells were bathed in a balanced salt solution containing 131 mM Na^+, 5.9 mM K^+, 5.4 mM Ca^{2+}, 0.8 mM Mg^{2+}, 0.1% glucose, 0.2% bovine serum albumin (BSA), and 25 mM HEPES, buffered to *p*H 7.4 with NaOH. The Ca^{2+} concentration was raised to 5.4 mM to increase inward Ca^{2+} currents and to improve the membrane seal around the microelectrodes. Known concentrations of drugs made up in recording medium were applied to individual neurones by pressure ejection from a 3–5-μm-tip micropipette positioned 100–200 μm from the impaled soma[8].

The action potentials of embryonic chick DRG neurones are composed of a fast Na^+ component blocked by tetrodotoxin (TTX) and a slower Ca^{2+} component that is in part responsible for the plateau during repolarisation[7]. γ-Aminobutyric acid (GABA), noradrenaline (NA), and 5-HT produced a reversible dose-dependent shortening of this plateau phase of the action potential (Fig. 1). In one series, 97% ($n = 36$) of the cells responded to GABA, 92% ($n = 52$) to NA and 83% ($n = 23$) to 5-HT. Dose–response curves for these drugs are shown in Fig. 2. The three drugs were found to exert their effects over approximately a 1,000-fold concentration range, but 5-HT and NA ($ED_{50} = 6 \times 10^{-7}$ M) were slightly more potent than GABA ($ED_{50} = 2 \times 10^{-6}$ M). With each drug, the maximum effect observed in control solution was a 60% reduction in spike duration measured at half amplitude.

Both the time course of drug action and the magnitude of the response were found to be dose related. Lower concentrations ($\sim 10^{-7}$–10^{-6} M) produced effects that lasted for several seconds, whereas return to control spike duration after application of higher drug concentrations (10^{-5}–10^{-4} M) took several minutes.

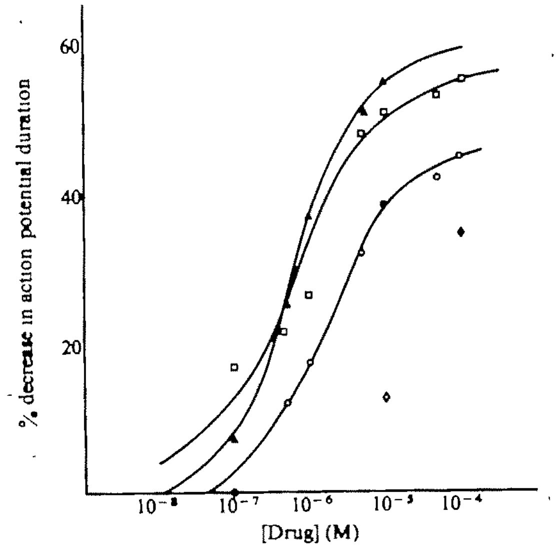
Glutamate produced a small and inconsistent effect on spike duration (Fig. 2). Only 8 of 17 cells responded to 10^{-5} or 10^{-4} M glutamate. ACh and glycine had no effect on the action potential in 10 neurones tested with 10^{-4} M. The fact that D-Ala-enkephalin amide and somatostatin at 10^{-6} M decreased DRG spike duration[5] was confirmed. Other peptides including substance P, bradykinin, neurotensin and thyrotropin-releasing hormone were ineffective at 10^{-5} M.

Resting membrane potentials (V_m) of the DRG neurones ranged between −36 and −64 mV, with a mean of -50.7 ± 0.7 mV (s.e.m., $n = 123$). Input resistance (R_m), measured as slope resistance through zero current, averaged ~50 MΩ. GABA, NA and 5-HT at concentrations of 10^{-7}–10^{-4} M did not alter these resting membrane parameters. A small decrease in R_m following application of 10^{-4} M GABA to DRG neurones has been observed within the first week after plating[8]. In these young cultures, the change in conductance was small, less than 4% of that observed in dissociated spinal cord neurones. No change in R_m was produced by GABA in the older cultures (> 1 week) used in this study. ACh at 10^{-4} M produced a 3–5 mV depolarisation associated with a small decrease in R_m.

We have begun to characterise the pharmacology of each response. The effect of 5×10^{-6} M GABA was not blocked by 10^{-4} M picrotoxin or 10^{-4} M bicuculline. These drugs are noncompetitive antagonists that block the GABA-mediated increase in Cl^- permeability at the crayfish neuromuscular junction[9] and in the vertebrate nervous system[10,11]. As no change in DRG resting membrane conductance was observed, it is not surprising that picrotoxin and bicuculline did not block the effect of GABA on the soma spike. Another kind of GABA receptor must be involved. The response to NA is apparently mediated by an α receptor: Selective α agonists, phenylephrine and dopamine at 10^{-5} M, were effective, whereas the β agonist, isoprenaline, at 10^{-5} M was not. Moreover, the effect of 10^{-5} M NA was blocked by 10^{-4} M phentolamine, an α antagonist, but not by 10^{-5} M propranolol, a β antagonist. Methysergide at 10^{-4} M did not block the effect of 10^{-5} M 5-HT.

The decrease in spike duration implies that the ultimate effect of GABA, NA and 5-HT is to decrease the duration of the inward Ca^{2+} current. It is not yet clear, however, if these drugs interact with Ca^{2+} channels directly. A decrease in spike duration might result from an increase in outward K^+ current.

Fig. 2 Dose–response curves for GABA (○), 5-HT (△) and NA (□) Responses to high concentrations of glutamate are included (◇). Each point is the average per cent in spike duration of a minimum of five neurones.



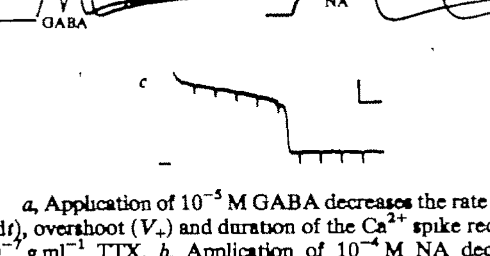


Fig. 3 *a*, Application of 10^{-5} M GABA decreases the rate of rise (dV/dt), overshoot (V_+) and duration of the Ca^{2+} spike recorded in 10^{-7} g ml^{-1} TTX. *b*, Application of 10^{-4} M NA decreases dV/dt, V_+ and duration of the Ba^{2+} spike recorded in TTX and 3 mM Ba^{2+}. *c*, Conductance during the plateau of a Ba^{2+} spike (5 mM Ba^{2+}) measured with hyperpolarising current pulses shows only a small increase in plateau conductance over rest. Calibration, 20 mV and 5 ms (*a*,*b*) and 100 ms (*c*).

Voltage-dependent and Ca-activated[12] K^+ currents must be considered. If this is the case, the outward current must occur early because GABA, NA and 5-HT also decrease the rate of rise and the peak amplitude of the Ca^{2+} spike (Fig. 3*a*). When the fast inward Na^+ current was blocked by 10^{-7} g ml^{-1} TTX, GABA (10^{-5} M) decreased the maximum rate of spike rise from 28 ± 2.6 V s^{-1} (mean ± s.e.m., $n = 10$) to 14 ± 2.5 V s^{-1} ($n = 10$) and the spike overshoot from 11.5 ± 1.1 mV (mean ± s.e.m., $n = 10$) to 3.0 ± 1.8 mV ($n = 10$). Moreover, the same drug effects were observed in the presence of 3 mM Ba^{2+} (Fig. 3*b*). (Ca^{2+} was held constant at 5.4 mM.) Ba^{2+} passes through activated Ca^{2+} channels[13] and blocks outward K^+ currents[14]. DRG spikes were prolonged in Ba^{2+} and the membrane conductance tested during the long plateau was low (Fig. 3*c*), indicating that K^+ channels were, in fact, blocked. Thus, considering the effect of the drugs on spike rate of rise and the persistence of the effect in the presence of Ba^{2+}, we favour a direct drug effect on Ca^{2+} channels. More direct evidence must be obtained by varying extracellular ion concentrations. In any case, our findings indicate that neurotransmitters may modulate voltage-sensitive neuronal membrane channels without producing a change in resting membrane parameters. Neurotransmitter modulation of voltage-sensitive channels has been described in studies of cardiac[15–17] and smooth[18] muscle.

Frank and Fuortes were the first to describe a type of inhibition of 1a e.p.s.ps that was not associated with a detectable change in the postsynaptic (motoneurone) membrane conductance[19]. The weight of evidence suggests that this 'remote' inhibition is primarily, if not entirely, due to inhibition of transmitter release from afferent nerve terminals[20,21] but the precise mechanism of presynatic inhibition remains obscure. Its temporal association with primary afferent depolarisation (PAD) has led to the notion that a transmitter-induced depolarisation of the primary afferent terminal reduces the size of the action potential and 1a transmitter output. GABA, the best studied neurotransmitter implicated in presynaptic inhibition, depolarises afferent nerve terminals (and nerve cell bodies)[11,22,23] by increasing the membrane permeability to Cl^- ions[11,23]. However, there is little direct evidence that this accounts for presynaptic inhibition.

Our results suggest an alternative mechanism. GABA decreases the influx of Ca^{2+} across the active soma membrane of cultured DRG neurones without producing a change in resting membrane conductance. If the same phenomenon occurs at nerve terminals this might effectively reduce transmitter release. It is interesting that this action of GABA is mimicked by 5-HT and NA because descending adrenergic (locus coeruleus)[24] and serotonergic (nucleus raphe magnus)[25] pathways have been described that terminate in the dorsal horn. Iontophoretically applied 5-HT and NA inhibit the firing of some neurones in superficial laminae of the dorsal horn[26]. Although the locus of this inhibition is not known, presynaptic actions of NA and 5-HT have been reported at other synapses[27,28]. It remains to be seen which mechanism, decreased Ca^{2+} conductance or primary afferent depolarisation, is responsible for presynaptic inhibition *in vivo*.

Adenosine inhibits the accumulation of cyclic AMP in cultured brain cells

ADENOSINE stimulates the accumulation of cyclic AMP in some tissues and cell types, but has inhibitory or biphasic effects on the accumulation of cyclic AMP in other cells. Londos and Wolff[1] have attempted to explain these diverse effects by the existence of two adenosine reactive sites on adenylate cyclase. The first is the R-site, occupancy of which usually leads to activation on adenylate cyclase and which for activity requires integrity of the ribose ring. Much evidence suggests that this site is identical to an extracellular receptor for adenosine[2–6]. The second type is the P-site, which mediates inhibition of adenylate cyclase and requires integrity of the purine ring for activity. Preliminary evidence suggests that this site is only accessible from the interior of the cell[1,3]. However, we report here that the inhibition by adenosine of the increase in the intracellular level of cyclic AMP evoked by isoprenaline in cultured glioblasts is mediated by extracellular receptors.

Brain cells from perinatal mice were obtained by mechanical dissociation of brain tissue and cultured as described previously[7]. The cultures consist mainly of epitheloid astroblasts[8], which can be differentiated into cells exhibiting astrocyte-like appearance[9]. They are considered as models for glial cells[7,10,11], as they express presumptive glial markers[12–15]. The cultures were incubated for 10 min at 37 °C in the presence of the various additions before the concentration of intracellular cyclic AMP

0028-0836/78/0276—0839$01 00

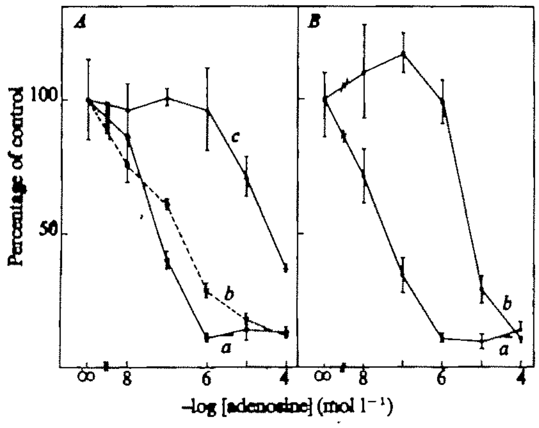

Fig. 1 Inhibition by adenosine of the elevation by isoprenaline (1 μM) of the level of cyclic AMP in mouse brain cell cultures in the absence (*A* and *B*, curve *a*) or presence of 0.5 mM Ro20-1724 (*A*, curve *b*), 0.5 mM MIBX (*A*, curve *c*) or, 0.5 mM theophylline (*B*, curve *b*). The culture for 24 d (*A*) or 20 d (*B*) of brain cells from perinatal mice (19–21 days *in utero*), the experimental incubation and the determination of cyclic AMP have been described elsewhere[7,16]. Protein content[28]:1.0 mg per plate. Controls (pmol cyclic AMP per mg protein): *A*: isoprenaline (1 μM), 580±90 (=100%); isoprenaline+Ro20-1724 (0.5 mM), 4,800±1,610 (=100%); isoprenaline+MIBX (0.5 mM), 4,700±290 (=100%); no addition, 7±2; adenosine: 1 μM, 8±2; 10 μM, 13±4; 100 μM, 16±3; Ro20-1724 (0.5 mM), 24±2, Ro20-1724 (0.5 mM)+adenosine: 1 μM, 22±4; 10 μM, 35±3; 100 μM, 73±13; MIBX (0.5 mM), 45±4 (duplicates); MIBX (0.5 mM)+adenosine: 10 μM, 44±2; 100 μM, 46±6. *B*: isoprenaline (1 μM), 480±70 (=100%); isoprenaline+theophylline (0.5 mM), 830±70 (=100%). All data given are mean values of triplicates ±s.d., except where indicated.

was determined[7,16]. Isoprenaline strongly elevates the level of cyclic AMP (ref. 7). This increase is inhibited by adenosine (Fig. 1*A* and *B*, curve *a*). Half maximal inhibition occurs at a concentration (IC_{50}) of 50–100 nM. The methylxanthines methylisobutylxanthine (MIBX) (Fig. 1*A*, curve *c*) and theophylline (Fig. 1*B*, curve *b*), known antagonists at adenosine receptors[2,3,5,17–20] and inhibitors of phosphodiesterase (PDE)[2,21], prevent this inhibition. The PDE-inhibitors 4-(3-butoxy-4-methoxybenzyl)-2-imidazolidinone (Ro20-1724) (ref. 22) (Fig. 1*A*, curve *b*), dipyridamole and papaverine[2,21], however, alone or in combination (not shown) do not substantially influence the inhibition by adenosine. The blockage by methylxanthines of the effect of adenosine is therefore due to their potency as antagonists at adenosine receptors and is not related to inhibition of PDE. Dipyridamole is not only a PDE-inhibitor but also a strong blocker of adenosine uptake into cells[2,4,23]. In the primary cultures investigated here, 100 μM dipyridamole inhibited the uptake of adenosine (concentration range 0.1–10 μM) by 80 to 90% (data not shown). Ro20-1724 and papaverine have also been reported to inhibit the uptake of adenosine[4,23]. Neither dipyridamole nor a combination of 0.5 mM Ro20-1724, 0.5 mM papaverine and 0.1 mM dipyridamole significantly reduced the effect of adenosine (data not shown). Accordingly, the effect cannot be due to an intracellular action of adenosine but must be mediated by extracellular receptors.

Table 1 Potencies of derivatives of adenosine in inhibiting in cultured brain cells the increase in the level of cyclic AMP caused by isoprenaline

Compound	IC_{50} (μM)
N^6-(Phenylisopropyl)adenosine	0.005
2-Chloroadenosine	0.1
N^6-Methyladenosine	0.5
Adenosine N^1-oxide	0.5
3′-Deoxyadenosine	5
2′-Deoxyadenosine	10
7-Deazaadenosine	10
9-β-D-Arabinofuranosyladenine	50
2′, 3′-Isopropylideneadenosine	100

Experiments were performed with cells cultured for periods extending from 14 d to 23 d. The level of cyclic AMP measured after stimulation with isoprenaline (1 μM) varied between 300 and 900 pmol per mg protein; 0.8–1.0 mg protein per plate. Other details as in Fig. 1.

These receptors are different from the adrenergic α- and β-receptors present on the cells[7] because: (1) methylxanthines antagonise the effect of adenosine (Fig. 1*A*, curve *c*, Fig. 1*B*, curve *b*) but not of α- or β-adrenergic agonists[7,11]; (2) a 1,000-fold increase in the concentration of isoprenaline does not overcome the inhibition by adenosine[11]; (3) the α-adrenergic antagonist phentolamine (100 μM) does not alter the effect of adenosine[11]. Thus, the receptors mediating the effect described here are probably specific for adenosine or a closely related compound.

The potencies of a number of derivatives of adenosine are summarised in Table 1. These results indicate that alterations in the ribose moiety of adenosine abolish the inhibitory potency of the nucleoside, whereas substituents in the purine moiety are comparatively well tolerated. This is consistent with the proposed[1] requirements of the R-site of adenylate cyclase. Adenosine not only inhibits but also stimulates the accumulation of cyclic AMP in the cultured brain cells[11,24]. Also, this stimulatory effect is mediated by extracellular receptors which show the stereochemical requirements of an R-site. N^6-(Phenylisopropyl)adenosine, however, a compound which is at least ten times more potent than adenosine in eliciting the inhibitory effect (Table 1), is only slightly less potent than adenosine in stimulating the accumulation of cyclic AMP in the cultures (our work, in preparation). Thus, the simplest explanation for these two effects of adenosine is the existence of two different types of receptor for the nucleoside. We propose the name A1-receptor for the one that mediates the inhibition and A2 for the one that mediates the stimulation of cyclic AMP accumulation.

The content of cyclic AMP in the incubation medium (about 20% of total) changed in proportion with the intracellular level of cyclic AMP. Thus, neither an increased release of cyclic AMP nor an increased degradation by PDE (Fig. 1*A*, curve *b*) can be responsible for the decrease in the intracellular accumulation of cyclic AMP. Thus the effect is likely to be due to inhibition of adenylate cyclase. This inhibition is probably a direct result of the binding of the A1-agonist to its receptor. Extracellular humoral factors distinct from adenosine are unlikely to mediate the effect. This was shown in the following way. After exposure to cells for 10 min, incubation medium containing 1 μM isoprenaline and 1 μM adenosine was treated with adenosine deaminase (Boehringer) to destroy adenosine. Cultures incubated with this medium revealed the same content of cyclic AMP as those exposed to control medium (only isoprenaline present) (data not shown).

Adenosine increases by way of extracellular receptors, the level of cyclic AMP in brain slices[4,17] and in cultured cells of glial[2,11] or neuronal[19–21,23] origin. However, a receptor-mediated depression by adenosine of the level of cyclic AMP in brain slices has not been reported nor has it been described for any other system, with possibly one exception. In intact rat fat cells low concentrations of adenosine prevent the increase in the level of cyclic AMP that is evoked by noradrenaline[25,26]. This effect is not blocked by dipyridamole[26]. Whether or not it is antagonised by methylxanthines remains to be clarified[27]. Interestingly, N^6-(phenylisopropyl)adenosine is also more potent in this system than adenosine[26]. Glial precursor cells which constitute the majority of the cells in the cultures[7,8] are probably responsible for the effects described. The presence of A1-receptors on cultured brain cells encourages investigations into the possibility that A1-receptors are also present on mature glial or neuronal cells in the brain.

The results presented here imply[7,11] that A1-receptors and β-receptors are probably located on the same cells, most of which also display adrenergic α-receptors[7,11]. Such a combination of receptors may be used as an identity label during isolation of the cells from heterogeneous populations.

Indomethacin in submicromolar concentrations inhibits cyclic AMP-dependent protein kinase

INDOMETHACIN is a potent inhibitor of prostaglandin synthesis[1,2], and has been used to demonstrate indirectly the mediation of biological events by prostaglandins. The rationale for this use of indomethacin has been supported when analytical techniques for direct prostaglandin quantitation have been used[3,4]. There are, however, conflicting data. A role for prostaglandins as the physiological messengers between hormones such as thyrotropin (TSH) and luteinising hormone (LH) and cyclic AMP has been proposed because prostaglandin antagonists inhibit the stimulatory effects of these hormones at their target tissues[5,6]. A similar role has been proposed in the action of cholera toxin[7,8]. In both cases, indomethacin failed to prevent the stimulatory effect of these agents on cyclic AMP production, giving support to the opposite view that prostaglandins were not essential intermediates[9–11]. Paradoxically, indomethacin suppresses, *in vivo*, thyroid hormone secretion[12] and cholera toxin-induced intestinal fluid accumulation[13–15]. A post-cyclic AMP site of action for indomethacin may explain these discrepancies. To elucidate the role of cyclic AMP-dependent protein kinase and endogenous protein phosphorylation in cholera toxin-induced intestinal secretion[16], we have tested the influence of indomethacin on partially purified protein kinase from rabbit ileal mucosa. We report here that indomethacin in submicromolar concentrations inhibits cyclic AMP-dependent protein kinase and endogenous protein phosphorylation.

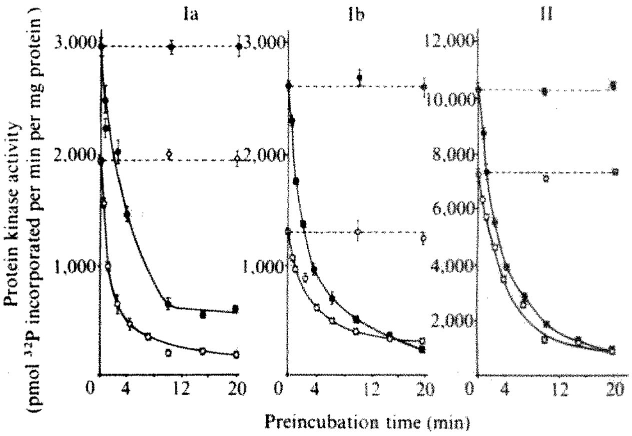

Fig. 1 Time-dependent blockade by indomethacin of types Ia, Ib and II cyclic AMP-dependent protein kinases. The standard assay mixture (final volume, 0.06 ml) for kinase activity contained: sodium α-glycerophosphate buffer (pH 7.5), 50 mM; dithiothreitol, 1 mM; protamine sulphate, 1.5 mg ml^{-1}; [γ-^{32}P]ATP, 6×10^{-4} M (10 μCi μmol^{-1}); magnesium chloride, 10 mM; enzyme protein, 0.02–0.2 mg ml^{-1}; ±cyclic AMP, 2×10^{-5} M and indomethacin, 1×10^{-7} M (solubilised by adding a minimum quantity of 0.1 M NaOH to the aqueous suspension of the drug). Enzyme protein was added to assay mixture containing all components except Mg^{2+}-^{32}P-ATP and preincubated for the indicated times at 30 °C with (●——●) and without (○——○) cyclic AMP. The reaction was started by the addition of Mg^{2+}-^{32}P-ATP. After incubation for 4 min at 30 °C, the reaction was ended by the addition of 1 ml of cold 10% trichloroacetic acid (TCA) followed by bovine serum albumin, 100 μg, as a carrier. The protein precipitate was collected on Whatman GF/C class fibre filters, washed 5 times with 1-ml portions of cold 10% TCA, transferred to 10 ml of a Triton toluene-based scintillant, and counted in a liquid scintillation spectrometer. Protein concentration was determined by the method of Lowry *et al.*[21] with bovine serum albumin as protein standard. Control values for protein kinase activity measured in the absence of indomethacin are depicted with (●----●) and without (○----○) cyclic AMP added. Each point represents the mean value ± s.e.m. obtained in 4 experiments carried out in a similar manner.

Homogenates of ileal mucosa were prepared by a modification of the method described previously[17]. The homogenation was carried out in 10 mM α-glycerophosphate buffer, pH 7.5, containing 1 mM dithiothrietol. A 150,000g cytosol fraction was prepared by the method of Uno *et al.*[18] and treated with solid ammonium sulphate followed by stirring for 30 min. Precipitation occurring between 30% and 55% saturation was removed by centrifugation at 20,000g for 20 min. The pellet was dissolved in and dialysed overnight against the α-glycerophosphate buffer. After dialysis the resulting solution was applied in a 2-ml volume to a column of DEAE-cellulose (1.5 × 60 cm) previously equilibrated with 10 mM α-glycerophosphate buffer (pH 7.5)/1 mM dithiothreitol. Protein kinases were eluted from

Table 1 Inhibition of rabbit ileal mucosa protein kinase activity and endogenous protein phosphorylation by indomethacin

	Protein kinase fractions					
	Ia		Ib		II	
Indomethacin effects	+Cyclic AMP	−Cyclic AMP	+Cyclic AMP	−Cyclic AMP	+Cyclic AMP	−Cyclic AMP
Inhibition (ID$_{50}$, M)						
Protein kinase activity	3.4×10^{-8}	1.7×10^{-8}	4.8×10^{-8}	1.7×10^{-8}	3.2×10^{-8}	1.8×10^{-8}
Endogenous protein phosphorylation	1.1×10^{-8}	0.60×10^{-8}	0.8×10^{-8}	0.62×10^{-8}	0.70×10^{-8}	0.58×10^{-8}
% Inhibition (1×10^{-7} M)	71 ± 2.1	84 ± 1.0	80 ± 1.2	88 ± 3.1	86 ± 1.0	87 ± 1.0

the column with a linear gradient (0–0.8 M) of NaCl. Three major cyclic AMP-dependent kinase activity peaks were resolved and arbitrarily designated types Ia, Ib and II. The peaks of protein kinase activity were eluted at the following approximate concentrations (in M) of NaCl: type Ia, 0.16; type Ib, 0.33; type II, 0.51. The active fractions under each peak were pooled and concentrated by ultrafiltration.

Our results demonstrate that indomethacin at submicromolar concentrations can inhibit the three active forms of cyclic AMP-dependent protein kinase resolved from rabbit ileal mucosa in a time-dependent and concentration-dependent manner. Indomethacin had no instantaneous effect on the rate of ^{32}P incorporation into protein substrate. After 4 min, the incubation time of the standard assay for protein kinase, the per cent inhibition ±1 s.e.m. at 10^{-7} M indomethacin was (+cyclic AMP/−cyclic AMP) $17\pm3.7/20\pm4.3$ for peak Ia, $11\pm2.1/17\pm3.8$ for peak Ib and $13\pm2.9/16\pm6.2$ for peak II. Preincubation of the enzyme for different times before the addition of substrate led to progressive inhibition (Fig. 1). These results suggest that indomethacin takes part in a time-dependent reaction before it can produce its maximal inhibitory effect. The inhibition of cyclic AMP-dependent protein kinase activity by indomethacin was concentration-dependent (Fig. 2), and could not be reversed by dilution of the inhibitor, suggesting it was either irreversible or a result of tight binding by indomethacin (data not shown). Putative phosphorylation of endogenous protein substrate was measured by the incorporation of ^{32}P from ^{32}P-ATP to trichloroacetic acid-insoluble material (without exogenous protamine as substrate) of each activity peak. The inhibition response was qualitatively similar to the results obtained when exogenous substrate is added (Table 1).

The ID_{50} (concentration of inhibitor required to inhibit 50% of enzyme activity)[19] and per cent inhibition are shown in Table 1. The ID_{50} for indomethacin, when computed for protein kinase activity, ranged from 1.7×10^{-8} M (−cyclic AMP) to 4.8×10^{-8} M (+cyclic AMP). The ID_{50} for endogenous protein phosphorylation ranged from 0.58×10^{-8} M (−cyclic AMP) to 1.1×10^{-8} M (+cyclic AMP). The per cent inhibition for protein kinase activity at 1×10^{-7} M indomethacin varied from 71% to 88%.

In addition to inhibiting prostaglandin synthetase, indomethacin exerts effects on a variety of enzyme systems at micromolar concentrations or greater[3], properties which should be kept in mind when using this drug to evaluate the role of prostaglandins in biological events. On a molar basis indomethacin was between 79 and 224 times more potent as an inhibitor of cyclic AMP-dependent protein kinase activity than of prostaglandin synthetase activity (rabbit kidney microsomes[3]). Furthermore, at normal therapeutic doses, the free plasma concentration of indomethacin (5.6×10^{-7} M)[4] is 12–33 times greater than the ID_{50} for protein kinase.

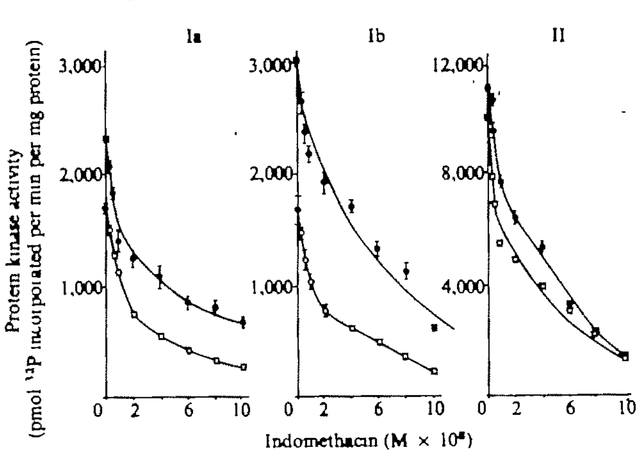

Fig. 2 Concentration-dependent inhibition by indomethacin of types Ia, Ib and II cyclic AMP-dependent protein kinase activities. Enzyme protein was added to the assay mixture containing the indicated concentration of indomethacin and preincubated for 20 min before starting the reaction by the addition of the substrate, Mg^{2+}-^{32}P-ATP. Each point, with (●——●) and without (○——○) cyclic AMP, represents the mean value ± s.e.m. obtained in 4 experiments carried out in a similar manner.

This study demonstrates that indomethacin is a potent inhibitor of cyclic AMP-dependent protein kinases and endogenous phosphorylation. It has been suggested that activation of protein kinase represents a major mechanism by which cyclic AMP carries out its function as an intracellular messenger in mammalian systems[20]. These data suggest that at therapeutic doses, indomethacin may function as an antagonist to cyclic AMP. Further studies are necessary to identify the mechanism of inhibition and to establish whether this new action of indomethacin occurs more generally in different tissues.

Agropine—a major new plasmid-determined metabolite in crown gall tumours

THE crown gall tumour system may represent an elegant form of biochemical parasitism, in which the tumour-inducing bacterium *Agrobacterium tumefaciens* can, by insertion[1] and expression[2] of genetic sequences carried on the tumour-inducing (Ti) plasmid[3], determine the synthesis of unusual amino acids in transformed plant cells. These abnormal metabolities can be specifically utilised as nitrogen sources by the particular strain of inducing bacterium[4]. So far, two classes of plasmid-determined product have been recognised: the octopine family—octopine[5], octopinic acid[6], lysopine[7] and histopine[8]—and the nopaline family—nopaline[9] and nopalinic acid[10]. Whether the octopine or nopaline family of amino acids is synthesised by a particular tumour depends entirely on the type of Ti plasmid present in the inducing bacterium[11]. We report

Table 1 Octopine, nopaline and agropine degradation by *A. tumefaciens* strains and synthesis by crown gall tumours induced by those strains

Bacterial strain	Bacterial degradation*			Synthesis in tumour†		
	Octopine	Nopaline	Agropine	Octopine	Nopaline	Agropine
A6	+	−	+	+	−	+
A66	+	−	+	+	−	+
B6	+	−	+	+	−	+
181	−	+	−	−	−	−
38-9	−	+	−	−	+	−
T-37	−	+	−	−	+	−
C-58	−	+	−	−	+	−

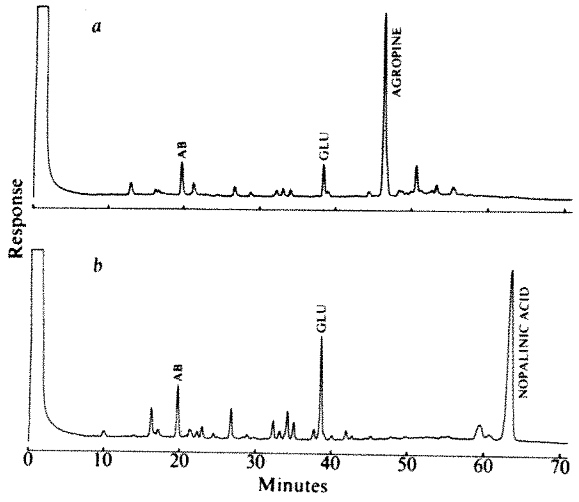
* Bacteria were inoculated into a liquid medium[16] containing either glucose (0.4% w/v) as C and energy source, and octopine (0.1% w/v) or nopaline (0.1% w/v) as sole N sources or agropine (0.1% w/v) as sole carbon and energy source, with ammonium sulphate (0.2% w/v) as N source. Agropine was isolated from an aqueous extract of A66-induced tumour tissue by adsorption on to Dowex 50×8, 20-50 mesh, H^+ form. The resin was washed with 10 bed volumes of water and eluted with 0.1 M ammonium hydroxide. Fractions equal to the column bed volume were collected, and those showing strong reaction with the alkaline silver nitrate reagent[13] after paper chromatography in propan-1-ol–ammonia (3:2 by volume) were combined and evaporated at 50 °C. When required, further purification was obtained by preparative paper chromatography. Cultures were shaken at 28 °C, and were examined for growth visually after 24 h. Disappearance of octopine or nopaline (measured colorimetrically using the α-naphthol-diacetyl reagent[17]) or disappearance of agropine (measured by gas chromatography[12]) correlated with visible bacterial growth.

† Synthesis of octopine, nopaline or agropine by bacteria-free tumour tissue was demonstrated by incubating the tumour tissue (~50 mg fresh weight) with either [U-^{14}C]arginine or [U-^{14}C]D-glucose (1 μCi, 304 μCi μmol^{-1}) for 24 h at 20 °C. The tissue was freeze dried and after grinding with sand, extracted with 2×5 ml water. After centrifugation the supernatant was passed through a column of Zerolit 225, 52-100 mesh, H^+ form, 1 ml bed volume. The resin was washed with water and cationic compounds (including octopine, nopaline and agropine) were eluted with 2M ammonium hydroxide. This eluate was concentrated by evaporation, and the individual compounds present were separated by two dimensional paper (Whatman 3 MM) chromatography (solvent I, 100 g phenol + 39 ml water; solvent II, butan-l-ol-propionic acid water 92:47:61), with added unlabelled octopine, nopaline and agropine. These compounds were located using either the Sakaguchi reaction[18] (octopine and nopaline) or the alkaline silver nitrate reagent[13], and the ^{14}C present in each compound was assayed by liquid scintillation. Radioactivity present in the agropine spot in '+' samples ranged from 1.7×10^4 c.p.m. (A66) to 3.4×10^4 c.p.m. (B6); '−' indicates c.p.m. $<10^2$. Lower limit of detectability was 10^2 c.p.m. No label was detected in agropine (added as a 'cold' standard before extraction) when healthy *N. tabacum* was incubated with ^{14}C-glucose as described above. R_f values for agropine were: solvent I 0.78; solvent II 0.25.

here the discovery of a completely new type of plasmid-determined compound which is present in prodigious amounts (up to 7% of the tumour dry weight) in tumours induced by octopine strains of *A. tumefaciens*.

Gas chromatograms of the heptafluorobutyric (HFB) *n*-propyl derivatives[12] of the free amino acids isolated from bacteria-free crown gall tumours initiated on 'White Burley' tobacco plants[10] by inoculation with any one of a series of octopine-metabolising strains of *A. tumefaciens* (A6, B6, A66) showed the presence of a major unidentified peak (Fig. 1*a*). This peak, which we have named 'agropine', was not detected either in tumours induced by nopaline-metabolising strains (Fig. 1*b*) of *A. tumefaciens* (C58, T-37, 38-9, 181) or in healthy tobacco tissue.

Fig. 1 Gas chromatograms of the HFB *n*-propyl derivatives[12] of the free amino acids extracted (see Table 1) from crown gall tumour tissue induced on *Nicotiana tabacum* by *A. tumefaciens* strain A66(*a*) and strain T37(*b*). AB, α-aminobutyric acid (added as internal standard); GLU, glutamic acid. Nopaline, although present in the T37 tumour at approximately the same level as nopalinic acid, does not chromatograph in these conditions.



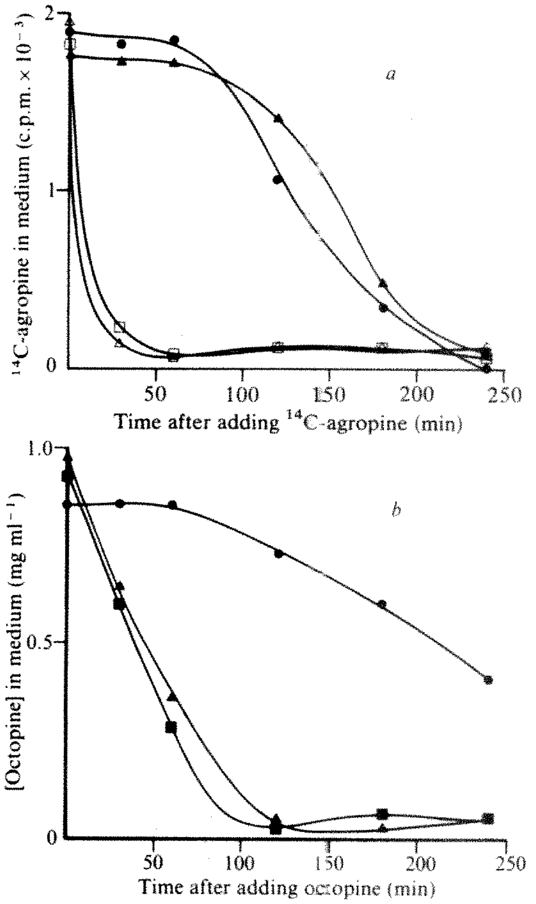


Fig. 2 Uptake of ^{14}C-agropine and octopine by *A. tumefaciens* strains. Bacteria were cultured at 28 °C in a liquid minimal medium[16] containing either glucose (0.4% w/v) + ammonium sulphate (0.2%), glucose (0.4%) + octopine (0.1%) or agropine (0.2%) + ammonium sulphate (0.2%). The bacteria were collected by centrifugation after 24 h, washed in minimal medium with no added carbon or nitrogen sources, and then resuspended in sufficient fresh minimal medium to give a final A_{630} value of 1.5. After addition of ^{14}C-agropine (~2×10^3 c.p.m., isolated from A66-induced tumour tissue after incubation with [U-^{14}C]glucose (see Table 1) or octopine (1 mg) the culture was shaken at 28 °C, and samples (10%) of the medium assayed, after centrifugation, by liquid scintillation (^{14}C-agropine uptake) or by the α-naphthol-diacetyl reagent[17] (octopine uptake). ●, Strain B6, not induced; ■, B6, induced with octopine; □, B6, induced with agropine; ▲, strain 1-1, not induced; △, 1-1, induced with agropine.

Transfer of the Ti plasmid from an octopine strain (B6S3) by conjugation in the presence of octopine (2 mg ml^{-1}), to a plasmid-cured rifampicin-resistant mutant of the nopaline strain C58, resulted in transconjugants (selected by plating on a minimal medium containing octopine (2 mg ml^{-1}) and rifampicin 25 μg ml^{-1}) which induced tumours containing agropine and octopine. These data suggest that agropine, like members of the octopine and nopaline families, is a strain-specific, plasmid-determined product.

The new compound was isolated (Table 1) from bacteria-free tumour tissue as colourless microcrystals from acetone–water, melting point 129 °C, $[\alpha]_D^{25}+19.5°$ ($c = 1$ in water). High resolution mass spectrometry indicated a molecular weight of 275.10254, corresponding to a molecular formula $C_{11}H_{17}NO_7$. Spectroscopic studies (IR, NMR) suggested a polyhydroxylic carboxylic acid. Gas chromatography of the HFB *n*-propyl derivative of purified agropine gave a single peak which co-chromatographed with the large peak found in the derivatised amino acid fraction from the tumour tissue. The molecule does not react with ninhydrin, but can be detected on paper using the alkaline silver nitrate reagent[13].

All octopine strains of *A. tumefaciens* (A6, B6, A66) examined so far utilise agropine as a sole carbon and energy source (Table 1). Uptake of agropine seems to be mediated by an inducible permease (Fig. 2*a*), and results obtained with the mutant octopine strain 1-1, which is constitutive for octopine uptake (Fig. 2*b*) and degradation, but not for agropine uptake (Fig. 2*a*) suggest that the uptake of octopine and agropine is controlled by different genes. Nopaline strains do not take up agropine after pregrowth in a minimal medium either with or without added octopine, nopaline or agropine, although these strains do transport and degrade octopine after pregrowth with nopaline.

The evidence suggests that agropine may represent a condensation product between a sugar or sugar derivative and an amino acid, and is therefore probably not synthesised by the enzyme responsible for synthesis of the octopine family of amino acids. Estimates of the amount of plasmid-derived genetic material in the tumour genome suggests that information sufficient to code for only four proteins of molecular weight ~50,000 is present[14]. Thus it is unlikely that agropine synthesis in the tumour could involve many intermediates not normally present in the plant tissue before transformation.

There is little doubt that agropine is not a normal plant product, although it is still conceivable that the capacity to synthesise agropine resides in the plant genome, and is only expressed in response to infection by a particular strain of infecting bacterium. However, this hypothesis is extremely unlikely since agropine is present in tumours induced on several unrelated genera of host plant[15].

In any event, the remarkably high levels of agropine present in tumours represent a major diversion of the plants' nutritional resources into a form which is specifically available as a carbon and energy source to the tumour-inducing pathogen. Agropine, together with the specific nitrogen sources octopine, octopinic acid, lysopine and histopine, could therefore provide the basic nutritional requirements of the pathogen in a form available only to that strain.

We thank Dr A. G. Hepburn, University of Bristol, for carrying out the bacterial conjugation.

A physically altered leucyl-tRNA synthetase complex in a CHO cell mutant

CONDITIONALLY lethal mutants in animal cells have been of great value in advancing our knowledge of genetics, biochemistry and molecular biology. Mammalian cells with temperature sensitive (*ts*) mutant phenotypes have been isolated by several laboratories, however no thorough characterisations of the altered gene products are available[1]. Selection procedures have been devised by Thompson *et al.* to isolate *ts* aminoacyl-tRNA synthetase variants in Chinese hamster ovary (CHO) cells which behave as missense mutants[2,3]. The CHO temperature-sensitive mutant *ts*H1 has very low *in vivo* levels of leucyl-tRNA, compared to wild-type levels at non-permissive temperatures; levels of the other 19 aminoacyl-tRNAs are unchanged[4]. This mutant also has an altered leucyl-tRNA synthetase which is thermosensitive *in vitro*[4], enzymatically different from wild-type leucyl-tRNA synthetase[5], and has an altered K_m for leucine[5]. We have now shown the leucyl-tRNA synthetase in *ts*H1 also has altered physical characteristics. The mutant enzyme exists primarily in a low molecular weight form whereas wild-type leucyl-tRNA synthetase is primarily associated with higher molecular weight particulate forms.

The particulate nature of aminoacyl-tRNA synthetases is a common feature of eukaryotic cells. The nature of these particulate enzyme forms reflects *in vivo* molecular organisation but its significance is not clear[6]. The size and form distributions of the 13 post-ribosomal particulate synthetases examined were indistinguishable in wild-type and mutant cells, except for leucyl-tRNA synthetase. The dramatic physical alteration of leucyl-tRNA synthetase is shown in Fig. 1. The distributions of

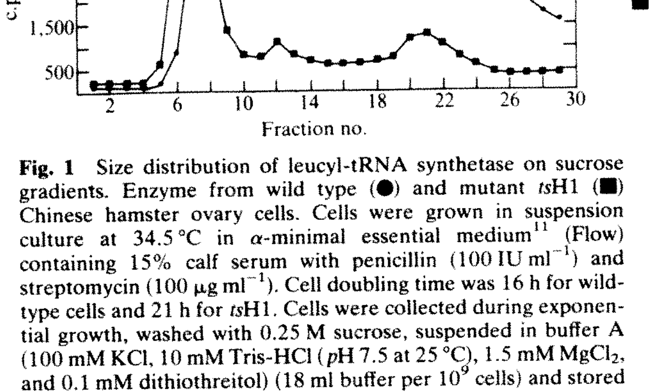

Fig. 1 Size distribution of leucyl-tRNA synthetase on sucrose gradients. Enzyme from wild type (●) and mutant *ts*H1 (■) Chinese hamster ovary cells. Cells were grown in suspension culture at 34.5 °C in α-minimal essential medium[11] (Flow) containing 15% calf serum with penicillin (100 IU ml^{-1}) and streptomycin (100 μg ml^{-1}). Cell doubling time was 16 h for wild-type cells and 21 h for *ts*H1. Cells were collected during exponential growth, washed with 0.25 M sucrose, suspended in buffer A (100 mM KCl, 10 mM Tris-HCl (*p*H 7.5 at 25 °C), 1.5 mM $MgCl_2$, and 0.1 mM dithiothreitol) (18 ml buffer per 10^9 cells) and stored at −90 °C. Cells (10^9) were broken in buffer A (20 ml) containing 1% Nonidet P-40 (Particle Data Labs) and supernatant was centrifuged at high speed to remove ribosomes. This postribosomal supernatant was centrifuged further to give a 6–40S subcellular pellet which was resuspended in buffer B (10 mM KCl, 10 mM Tris-HCl (*p*H 7.5 at 25 °C), 1.0 mM $MgCl_2$, and 0·1 mM dithiothreitol), layered on 10–30% w/v logarithmic sucrose gradients in buffer B, and centrifuged for 22 h at 25,000 r.p.m. in a Spinco SW-25.2 rotor at 4 °C (refs 12, 13). Sucrose gradients were assayed for the amino acids Arg, Asp, Cys, Gln, Glu, His, Ile, Leu, Lys, Met, Pro, Thr, and Val by esterifying ^{14}C-amino acids to cognate rat liver tRNAs and determining products formed (^{14}C-aminoacyl-tRNAs)[13,14].

Mammal Photography and Observation

A Practical Field Guide

L. J. Warner

February/March 1979, approx. 300pp., £4.95/$10.25 0.12.735650.9

This fascinating work is no technical or theoretical textbook but a practical guide to a rewarding pastime — the observation and photographing of mammals. Whether its results are skilful portraits of animals or simply enjoyment and increased knowledge of the mammal's behaviour matters little. In either case, the person, be he photographer or naturalist, will greatly benefit from reading this book. Based on personal field experience, the book includes chapters on most of the common species that can be found in the British Isles and Europe, with extended sections on badgers, foxes and deer. The book is illustrated with 130 of the author's photographs, all previously unpublished.

Methods In Microbiology Volume 12

edited by T. Bergan and J. R. Norris

February/March 1979, approx. 300pp., £12.00/$24.75 0.12.521512.6

This book continues the series of four Volumes which describe the methods available for typing the major human pathogens. It will provide a valuable reference work for microbiologists working in the epidemiological field and a valuable orientation to this important area of microbiology. *Volume 12* begins with a general article on the serotyping of bacteria and then presents three short Chapters on the characterisation of *Yersinia enterocolitica*. Two Chapters deal with *Vibrio cholerae* and the rest of the Volume is concerned with the Gram-positive cocci including Chapters on *Staphylococcus*, haemolytic streptococci, enterococci, bacteriocin typing of streptococci and the identification and characterisation of *Streptococcus pneumoniae*.

Pests of Grain Legumes: Ecology and Control

edited by S. R. Singh and H. F. van Emden

February/March 1979, xvi + 454pp., £14.50/$30.00 0.12.646350.6

Grain legumes form an important part of the world's food crops especially in the tropics where they are the staple diet for many people. With the increase in research on these crops in recent years, it has become apparent that considerable loss in yield can occur as a result of insect pests. Entomologists working to try and reduce this problem, felt that more exchange of information was necessary and that a reference book specifically on grain legume entomology would be particularly welcome at this time. This volume, it is hoped, fulfils these requirements. It has its origins in an international symposium on pests of grain legumes, held at the International Institute for Tropical Agriculture, Ibadan, Nigeria.

Practical Aspects of Memory

edited by M. M. Gruneberg, P. E. Morris and R. N. Sykes

January/February 1979, xiv + 786pp., £18.60/$38.50 0.12.305050.2

The practical significance of most memory research has been less well developed than theoretical studies, and in view of this the Welsh branch of the British Psychological Society held an International Conference on Practical Aspects of Memory in Cardiff, Wales, from 4th-8th September, 1978. The Conference aimed to examine ways in which the advances made in the theoretical understanding of memory could be applied to 'real life' memory problems, and also ways in which an attack on real-life problems could throw light on aspects of theoretical interest and importance. Both the Conference and this book, which comprises most of the papers presented, are the first of their kind devoted wholely to practical aspects of memory. The book is undoubtedly the widest and most far-ranging treatment of the topic yet produced, and includes general considerations of memory in everyday life, educational implications of memory research, and the clinical significance of memory research to brain damage and drug effects.

The Properties of Diamonds

edited by J. E. Field

February/March 1979, approx. 650pp., £32.50/$67.25 0.12.255350.0

In 1965 Dr R. Berman edited a book on the *Physical Properties of Diamond*. The justification for the present book is the tremendous advance in research on diamond since that time. This has been stimulated by the continued co-operation between the diamond industry and a number of British Laboratories. The scope of the present book is larger than its predecessor since it not only covers research on the solid state and mechanical properties of diamond, but also includes valuable chapters on the applications of diamond and its products, on its geological formation and on its synthesis.

the 12 indistinguishable activities are not shown here, as similar wild-type profiles have been previously published[6].

The wild-type leucyl-tRNA synthetase shows three particulate forms: an 8S form, a 20S form and a 30S form. Most of the wild-type enzyme activity is reproducibly found in the large 30S particle, and the mutant leucyl-tRNA synthetase is predominantly found in the small 8S form. The mutant leucyl-tRNA synthetase maintains negligible amounts of the higher molecular weight forms. These differences in synthetase forms provide additional evidence that the cause of the *ts*H1 phenotype is a directly altered leucyl-tRNA synthetase. These differences alone do not exclude the possibility that the shifts in leucyl-tRNA synthetase are due to a change in the molecules with which the enzyme is complexed, rather than a change in the leucyl-tRNA synthetase itself. However, previous studies on the mutant cells show this to be unlikely[4,5].

The physical evidence for a structurally altered leucyl-tRNA synthetase further supports the original evidence of Thompson *et al.*[4] that *ts*H1 is a true genotypic variant with an altered gene product and further counters epigenetic theories that somatic cell variants have stable phenotypes but do not contain changes in DNA structure. The electrophoretically altered hypoxanthine-guanine phosphoribosyltransferase from mutant HeLa cells[7-9] and cyclic AMP-dependent protein kinase from mutant S49 lymphoma cells[10] represent strong physical evidence for the existence of directly altered gene products and, consequently, stable genetic variants. The fact that the *ts*H1 gene product, leucyl-tRNA synthetase, is temperature-sensitive *in vitro*, and is apparently physically altered as well, suggests that it is also structurally altered due to a missense mutation in the structural gene.

The difference in synthetase forms between this mutant and wild-type cells is also very good evidence that the particulate nature of aminoacyl-tRNA synthetases is not an artefact but indeed a real intramolecular assemblage. The fact that large particulate forms of leucyl-tRNA synthetase are largely absent in the mutant although the mutant still survives suggests the complex is not completely essential for cellular function in the conditions described in this report. This mutant should prove very useful in determining the cellular role of the particulate forms of this enzyme.

Nucleotide sequence at the insertion sites of a kanamycin transposon

THE TRANSPOSON Tn*903* carrying a gene for kanamycin resistance, is 3,100 base pairs in size and contains an inverted repeat sequence of 1,050 base pairs at both ends[1-4]. We report here the generation of a 9-base pair repeated sequence at the insertion site of Tn*903*. Tn*903* can be transposed to at least nine different sites on the coliphage fd DNA[1,2]. We have also transposed Tn*903* to three sites on small colicin E1 plasmid (ColE1) derivatives of about 1,600 base pairs. The presence of these many insertion sites on small recipient DNA molecules implies that no specific sequence is involved in the target sites on the recipient. To investigate the mechanism of transposition of Tn*903* at the molecular level, we have now analysed three independent insertions of Tn*903* on the small ColE1 DNA molecules. The nucleotide sequences of the three target sites and of the corresponding junctions between Tn*903* and the small ColE1 have been determined.

The small ColE1 derivatives used were pAO2 (ref. 5) and pAO3. pAO2 is constructed from the region between 0.75 and 1.00 map units of the ColE1 DNA molecule. (A map unit is the fractional length from the 5′ end of the H-strand[6] generated from ColE1 DNA by cleavage with the restriction endonuclease *Eco*RI.) pAO3 is similar to pAO2 but carries an additional region of 70 base pairs (Fig. 1). pAO43 (pAO2::Tn*903*), pAO48 (pAO2::Tn*903*) and pAO65 (pAO3::Tn*903*) were chimaeric plasmids carrying Tn*903*, constructed by transposing Tn*903* from R6-5 to either pAO2 or pAO3. These chimaeras contained a complete set of Tn*903*, demonstrated by their ability to donate the kanamycin marker to phage fd and λ*b5*. Restriction endonucleases used were *Hae*III, *Hap*II, *Hga*I, *Hha*I, *Bpa*I, *Bpa*II, *Hin*dIII and *Eco*RI. Methods for preparation of enzymes, plasmid DNA and restriction fragments have been described earlier[5,7]. DNA sequencing was carried out as reported by Maxam and Gilbert[8].

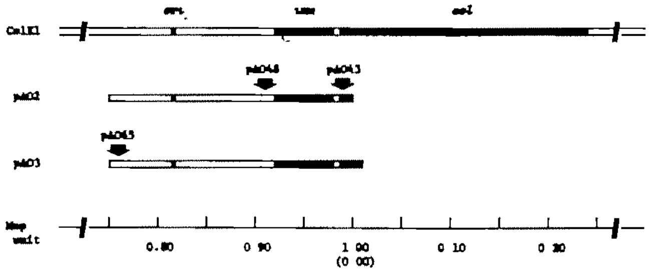

Fig. 1 Insertion sites of Tn*903* on the small ColE1 DNA molecules. The Tn*903* insertion sites in pAO43, pAO48 and pAO65 are shown by an arrow on the genetic map of pAO2 and pAO3. At the top is part of the genetic map of ColE1 as reference. DNA replication initiates at *ori* and proceeds towards the left. *col* is the structural gene of colicin E1 protein and *imm* is a gene conferring immunity to colicin E1 upon the host cell. The map position is indicated by the map unit of ColE1.

The Tn*903* insertion sites in pAO43, pAO48 and pAO65 were determined by comparison of restriction fragments produced from these plasmids with those from pAO2 or pAO3 by digestion with various restriction endonucleases (data not shown), and the sites were assigned to be 0.99, 0.91 and 0.76 map units on the small ColE1 DNA molecules, respectively (Fig. 1). The cleavage maps[5] around the three insertion sites and restriction fragments used for sequence analysis are shown in Fig. 2. The sequences within and surrounding the three insertion sites deduced are presented in Fig. 3*a–c*, in comparison with those in the corresponding region of pAO2 or pAO3. There are two particularly noteworthy features of the sequence. First, the two ends of Tn*903* are identical for at least 250 base pairs from the insertion site (Fig. 3*d*), in agreement with previous

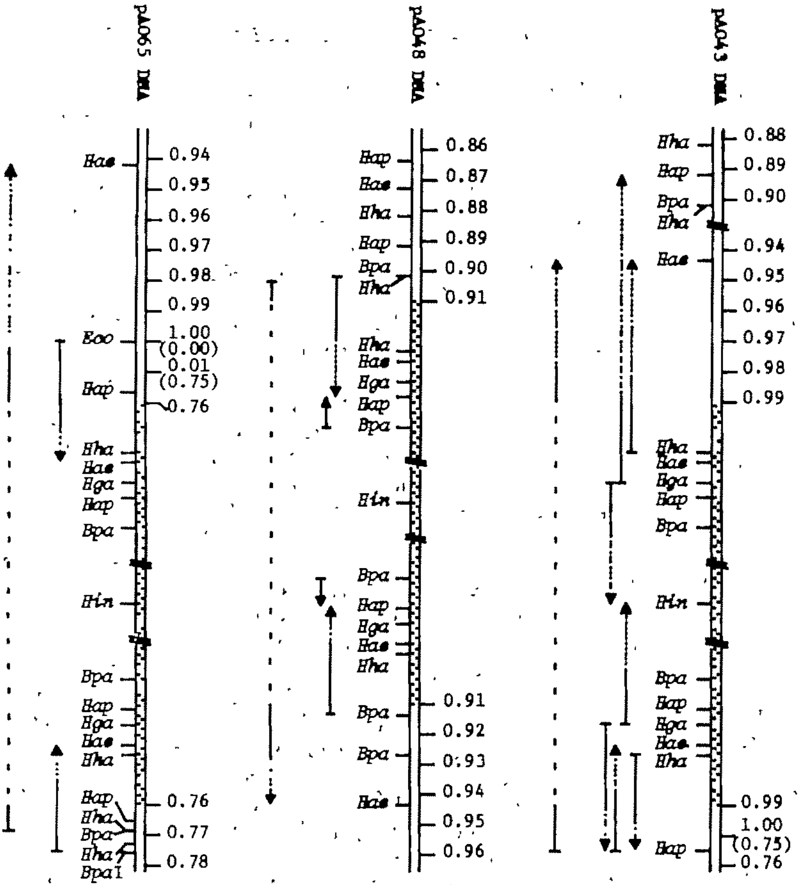

Fig. 2 Cleavage maps around the three insertion sites of Tn*903* and labelled strands used for sequence analysis. The map position is indicated by the map unit of ColE1 on each plasmid DNA. Cleavage sites by restriction endonucleases are shown under plasmid DNA: *Hae*, *Hap*, *Hha*, *Hga*, *Bpa*, *Hin* and *Eco* represent *Hae*III, *Hap*II, *Hha*I, *Bpa*II, *Hin*III and *Eco*RI, respectively. Arrows indicate [5'-^{32}P]labelled strands aligned in the 5' to 3' direction. The bottom arrow in each plasmid is a strand prepared from pAO2 or pAO3 DNA. All the strands were obtained by secondary cleavage of [5'-^{32}P]labelled double-stranded DNA. Solid lines in the arrows indicate the sequences that were resolved, and the dotted portions of the arrows indicate the sequences that were not as well resolved. The shading represents the Tn*903* DNA.

Fig. 3 The nucleotide sequence surrounding the Tn*903* insertion sites. The upper part in *a*, *b* and *c* represents the nucleotide sequence of the pAO2 or pAO3 DNA molecule, surrounding the Tn*903* insertion sites. The lower part in *a*, *b* and *c* shows the nucleotide sequence covering the junction between Tn*903* and either pAO2 or pAO3 in pAO43, pAO48 and pAO65, respectively. ▽ shows the duplication of 9 base pairs on Tn*903* insertion. *d*, The nucleotide sequence of the inverted repeat carried by Tn*903*. This sequence represents approximately 25% of the inverted repeat sequence. Nucleotide position is numbered from the integration site.

heteroduplex analyses[1,2,4]. This sequence has no obvious similarities to those of IS*1* and IS*2* (refs 9–12). Second, a 9-base pair segment, present at the site of insertion on the recipient DNA molecule, is repeated in the same orientation at both ends of Tn*903*. It is unlikely that the 9-base pair segment was brought from R6-5 as the donor of Tn*903* , because the sequence of 9-base pair repeat is different for each insertion analysed. Similar repetition has also been observed with insertion of IS*1* (refs 9, 10), Tn*3* (E. Ohtsubo, personal communication) and Tn*5* (H. Schaller, personal communication). Therefore, it seems that this duplication is a general feature of the Tn and IS translocation process, suggesting all Tn and IS use a similar mechanism of transposition.

The creation of a 9-base pair can be explained as follows. Two single-strand cuts separated by 9-base pairs are introduced on opposite strands of the recipient DNA molecule. The two new 5′ ends formed at the insertion site are then joined to the 3′ termini of Tn*903* so as to conserve the nine bases of the recipient DNA at both sides of the Tn sequence. The unpaired gaps at the complementary strands are then filled by repair synthesis. A similar explanation has been discussed in detail by Caros *et al.*[9] and Grindley[10].

Comparison of the three target sites indicated that neither the duplicated regions nor their vicinity contained an unique sequence common to three insertions. This suggests that no recognition of a specific sequence (recognition sequence) is involved for Tn*903* translocation, and that Tn*903* can be transposed to any site on DNA. However, we cannot rule out the possibility that the recognition sequence occurs very far from the target site for insertion.

We thank A. Maxam and W. Gilbert for providing the details of the procedure for determining DNA sequences before publication, S. Cohen, P. Kretschmer and H. Yamagishi for bacterial and phage strains, and E. Ohtsubo and H. Schaller for sending us their results before publication. The chromophore binding space of opsin

THE rate of the reaction between opsin and 11-*cis* retinal, that gives the visual pigment rhodopsin, is measured in the presence and absence of structural analogues of 11-*cis* retinal, the polyene side chain of which is varied systematically. A decrease in regeneration rate can be interpreted as competition with 11-*cis* retinal for the binding site on the protein. This approach seems to provide information on the molecular dimensions of the chromophore binding space of opsin. Rotmans noticed that all-*trans* retinal does not inhibit the reaction between opsin and 11-*cis* retinal leading to rhodopsin[1]. More recently Mastumoto and Yoshizawa[2] have reported that β-ionone, a compound carrying the six-membered ring configuration of retinal but with a shorter side chain, does inhibit the rate of this reaction. The surprising discrepancy between these two observations has led us to study more systematically the effects on the regeneration rate of a number of 11-*cis* retinal analogues, in which either the polyene side chain or the aldehyde group has been modified. We report here results that suggest that opsin possesses a specific chromophore binding space, one dimension of which is determined by the longest axis of 11-*cis* retinal, measured from the hydrophobic binding site onwards.

Opsin, virtually free of rhodopsin, retinal and retinol, was prepared by sucrose density gradient centrifugation of bovine retina homogenate illuminated in the presence of NADPH (ref. 3). Aliquots were stored at −70 °C until used. 11-*cis* Retinal was isolated from a photoisomerate of retinal[4] (Eastman) and 11-*cis* retinol was prepared by $NaBH_4$ reduction of 11-*cis* retinal[5]. The purity of all compounds used was checked by spectrophotometry and thin-layer chromatography.

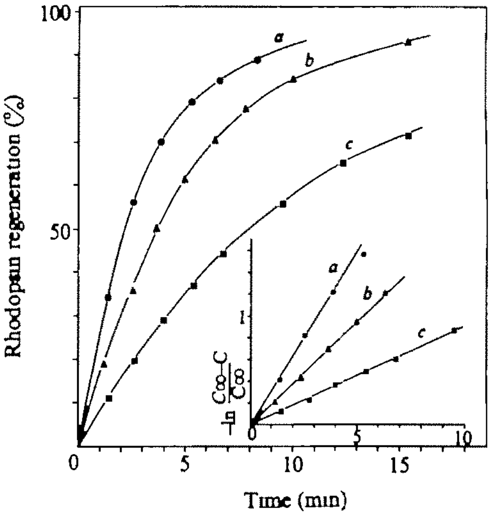

Fig. 1 Rate of the reaction between opsin and 11-*cis* retinal. *a*, In the absence of analogue; *b*, in the presence of the analogue 'C_{18}-ketone' (see Fig. 2*c*); *c*, in the presence of 'C_{15}-aldehyde' (see Fig. 2*b*). Reaction conditions, [opsin] = 9.5 μM; [11-*cis* retinal] = 48.5 μM, [analogue] = 500 μM; pH 6.5; 20 °C. Inset, semi-logarithmic plot.

The rate of the regeneration reaction was measured in a capped cuvette with two identical compartments. One compartment contained 600μl of the opsin suspension (19 μM in phosphate buffer) to which 10 μl of ethanol was added, either with or without the short chain analogue to be tested. The other compartment contained an equal volume of a suspension of 11-*cis* retinal (97μM in phosphate buffer, freshly prepared by adding the 11-*cis* retinal dissolved in 10 μl of ethanol). An initial absorption spectrum was recorded (Pye Unicam SP-1750, 20 °C), and the reaction started by mixing the contents of the two compartments. At various time intervals the absorption spectrum was recorded between 650 and 450 nm. The increase in absorbance at 520 nm (corrected for scattering differences at 650 nm) is used to measure the rate of rhodopsin synthesis[6]. Alternatively, aliquots were taken from the reaction mixture at various time intervals. The regeneration reaction was stopped by addition of NH_2OH (final concentration 100 mM), followed after 10 min by Triton X-100 (final concentration 1%); 500 nm absorbance was then measured before and after illumination. Both methods give essentially the same results. Difference spectra always indicate the formation of rhodopsin with λ_{max} 500 nm.

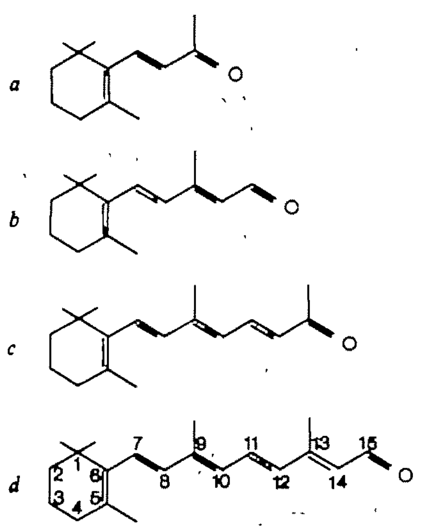

Fig. 2 Schematic structural formulae of short chain analogues of retinal. *a*, β-ionone; *b*, 'C$_{15}$-aldehyde', C$_{15}$H$_{22}$O, β-(3-methyl-5-oxo-1,3-all-*trans*-pentadienyl)2,6,6-trimethylcyclohexene; *c*, 'C$_{18}$-ketone', C$_{18}$H$_{26}$O, β-(3,7-dimethyl-7-oxo-1,3,5-all-*trans*-heptatrienyl)2,6,6-trimethylcyclohexene; *d* all-*trans* retinal.

Outer segment membrane suspensions rather than detergent solutions of opsin[2,6,7] have been used to approach the natural microenvironment of the protein as closely as possible. A fivefold molar excess of 11-*cis* retinal with respect to opsin was used. This results, in our conditions, in almost perfect first order kinetics over a large part (>65%) of the regeneration reaction, both in the presence and absence of analogues (Fig. 1). When 11-*cis* retinal is added to opsin as a very concentrated solution, a biphasic reaction is observed with a very rapid first phase. The analogues were preincubated for 10 min in the opsin suspension in a 10-fold molar excess with respect to 11-*cis* retinal. In this way reproducible results can be obtained.

Table 1 Apparent pseudo first order rate constants of the reaction opsin + 11-*cis* retinal → rhodopsin, in the presence and absence of various retinal analogues

Analogue	k_{app}(min^{-1})
No addition	0.33
β-Ionone	0.083
'C$_{15}$-aldehyde'	0.092
'C$_{15}$-alcohol'	0.084
'C$_{18}$-ketone'	0.20
All-*trans* retinol	0.19
11-*cis* retinol	0.18
All-*trans* retinal	0.32
13-*cis* retinal	0.36

Measurements of the regeneration rate of rhodopsin are presented in Fig. 1*a*. From the semilogarithmic plot (inset, *a*) a pseudo first order rate constant (k_{app}) of 0.33 min^{-1} was calculated. With regard to the effects of the analogues on the reaction rate, three patterns can be distinguished (Fig. 1, Table 1): (1) no effect is seen with all-*trans* as well as with 13-*cis* retinal (Fig. 1*a*), (2) moderate inhibition is observed with the 'C$_{18}$-ketone', all-*trans* retinol and 11-*cis* retinol (Fig. 1*b*), (3) strong inhibition is caused by β-ionone, the 'C$_{15}$-aldehyde' and the 'C$_{15}$-alcohol' (Fig. 1*c*). Varying the concentration of inhibitors between 0.25 and 5 mM shows that competitive inhibition occurs; the presence of even a large excess of analogues never prevents complete regeneration of rhodopsin.

An explanation of these observations originates from the conclusion of Matsumoto and Yoshizawa[2], that β-ionone competes with 11-*cis* retinal for a binding site on opsin. We observe that the 'C$_{15}$-aldehyde' inhibits the regeneration reaction to the same extent. As in the case of β-ionone[2], the presence of the aldehyde group is not essential, for the 'C$_{15}$-alcohol' gives essentially the same result. This seems to confirm the concept of a specific hydrophobic binding site for the trimethylcyclohexene ring on opsin. On extending the side chain of the analogues, the importance of a second parameter becomes apparent. The inhibition decreases markedly in the case of the 'C$_{18}$-ketone' and all-*trans* retinol. These two compounds contain a side chain with a rigid part consisting of four conjugated all-*trans* double bonds. It appears that the presence of a side chain, with a rigid part longer than that in the 11-*cis* retinal molecule, hinders the interaction of the six-membered ring moieties of these analogues with the hydrophobic binding site on opsin. This assumption seems to be supported by the fact that all-*trans* retinal, containing five conjugated all-*trans* double bonds in the side chain, does not inhibit the regeneration rate at all. Whereas the fairly high selectivity of retinal analogues with regard to the formation of visual pigments[8–11] suggests the existence of a rather specific chromophore binding space in rhodopsin, our findings indicate that such a specificity, with regard to the longest axis of the chromophore, is already present in the opsin molecule before the formation of visual pigment has taken place[12].

The effects of 11-*cis* retinol (moderate inhibition) and 13-*cis* retinal (no inhibition) are qualitatively compatible with our model. They may provide more refined information about the chromophore binding space of opsin, once their three-dimensional structure is known exactly.

In conclusion, competitive effects of retinal analogues with 11-*cis* retinal on the kinetics of the regeneration of rhodopsin from opsin provide information about the chromophore binding space of opsin. Apart from a previously noted[2] hydrophobic binding site for the six-membered ring of 11-*cis* retinal, it appears to be characterised by specific dimensions. The longest dimension of this space seems to coincide approximately with the long axis of the 11-*cis* retinal molecule.

I thank Cor Jacobs and Dr J. L. Baas for analogues. This investigation was carried out with financial support from the Netherlands Organization for Basic Research (ZWO) through the Netherlands Foundation for Chemical Research (SON).

Nature Index and Binders

The complete **Index** for 1977 is available, price £2.50 (UK), US$5.00 (Rest of World). Copies of the 1976 Index are still on sale, prices as above

Binders for the journal are also available at £8.00 (UK), US$16.00 (Rest of World) for three: a year of *Nature* fits into three binders.

All prices include postage. Payment may be made in any currency at the prevailing exchange rate. Orders should be sent, accompanied by remittance, to Macmillan Journals Ltd, Brunel Road, Basingstoke, Hampshire, RG21 2XS, UK.

matters arising

Premelting near crystal defects

BARTIS[1] has suggested that the premelting increment in heat capacity, which has been observed for some materials to be of the form

$$\Delta C = A/(T_m - T)^2 \qquad (1)$$

may arise from melting below the intrinsic bulk melting point, in the vicinity of point defects. He also suggested that premature melting may occur in the vicinity of edge dislocations resulting in an incremental heat capacity of the form

$$\Delta C = B/(T_m - T)^3 \qquad (2)$$

The important question arises as to whether the constants A and B are large enough to account for the observed magnitude of the premelting heat capacity. We show that B is too small for the dislocation contribution to be significant, but that for lattice vacancies A is about as large as the observed magnitude.

Gronvold[2] records that 99.99% purity bismuth is 2% molten 3 K below the atmospheric pressure melting point. By using standard expressions for the excess pressure about a dislocation[3] one finds that a dislocation density in excess of 4×10^{14} lines m^{-2} is required to admit such a degree of premelting. Such a density is three to four orders of magnitude higher than the largest density one might expect for a stable dislocation array just below the melting point. For a more likely dislocation density at the melting point of 10^{10} lines m^{-2} bismuth would be 0.1% molten 0.07 K below its normal melting temperature which may be just within the limits of observation, but this may require a prohibitively high purity sample[2].

Neither, it seems, does the dislocation core melt at all. The problem of core melting of dislocations may be treated in the same manner as core sublimation as detailed by Frank[4]. He concluded that for all dislocations with Burgers' vector <1 nm the core is not hollow. This includes all simple metals and ionic crystals. Similarly, in the case of melting below the bulk melting temperature, it can be shown[5] that the melt radius for these crystals is always less than the core radius and therefore that core melting does not occur.

These ideas are borne out by experiment. Allnatt and Sime[6] have studied the premelting rise in the electrical conductivity of NaCl after 5% compressional deformation and concluded that no contribution to the premelting arises from the dislocations, and although the premelting surface conductivity is altered by deformation,[7] this is not due to dislocation core melting. Moreover, Amelinckx and Dekeyser[8], in reviewing the relevant experimental data, conclude that intrinsic melting does not measurably occur at grain boundaries.

It seems that premature melting near dislocations either does not occur or is so small as to be immeastırable. There may, however, be a possible source of premelting behaviour as described by equation (1), in the vicinity of vacancies. A vacancy in a metal usually results in a local decrease in pressure which, in the referenced case of bismuth, increases the local melting point, and this precludes vacancy-originated premelting. However, in the case of metals with normal melting curves the local melting temperature is depressed. A calculation of the magnitude of A in equation (1) reveals that the effect is sufficiently large to explain premelting over a degree or so below the melting point. This is illustrated by considering the depression of melting point that would occur if the total free energy of a system of vacancies were distributed uniformly through the crystal lattice. For a mole fraction α of vacancies with a Gibbs' function of formation of g_v each, in a crystal with a molar entropy of melting of ΔS_m the depression is approximately

$$\Delta T = \alpha N_A g_v / S_m, \qquad (3)$$

where N_A is Avogadro's number. For the following typical values for metals: $g_v \sim 1$ eV, $\Delta S_m \sim 8.5$ J mol^{-1} K^{-1} and α $(T = T_m) \sim 10^{-4}$ we find $\Delta T \sim 1$ K. There may therefore be observable premature melting in the vicinity of lattice vacancies.

BARTIS REPLIES – I question Tallon's assessment of the stresses around edge dislocations. If the stresses are weak, then why are nucleation and growth alongside dislocations observed so often in structural studies of polymorphic transformations? Take, for instance, the passage of manganous oxide from the paramagnetic to the antiferromagnetic state. In neutron scattering from a single crystal above the Néel point Renninger *et al.*[1] detect peaks with satellites near the superlattice positions. They ascribe these features of the diffraction pattern to small domains of the magnetically ordered form of MnO. Using an electron microscope, Barber and Evans[2] do find small antiferromagnetic regions near dislocations and inclusions of Mn_3O_4 some 25 K above T_N. In the light of these results it is especially difficult to accept Tallon's claim that premelting does not occur in the cores of crystal dislocations.

The Golgi complex and inter-relationships of arthropods

LOCKE AND HUIE have reported[1] that the Golgi complex beads in a wide range of arthropods, but not in the Onychophora or other soft-bodied invertebrates, have a common feature—they stain with bismuth. They suggest that this favours a monophyletic rather than a polyphyletic concept of arthopod evolution. It should be remembered, however, that the taxa listed with similar Golgi staining also depend on unstriated muscle (which facilitates extensive shape changes of the body), in contrast to the sclerite-bearing arthopods. The significance of the similarity between Golgi phenomena and unstriated muscle is obscure. However, it is well known that striated muscle would not suit the requirements of the Onychophora[2–6]. Also, it is certain that striated muscle has evolved more than once in the animal kingdom. The presence or absence of striated muscle in the Onychophora and in armoured arthropods seems to be of no more than functional significance.

Locke and Huie's opening paragraph does not seem to agree with present-day views on arthropod phylogeny. To take one point: by 1972 it was time to abandon the cumbersome phrase 'Onychophora–

0028–0836/78/0276—0849$01.00

Myriapoda–Hexapoda assemblage' and to give a name, the Uniramia, to this group[7]. The component taxa are united on their basic arthropodan features; their particular type of jaws, and their limbs lacking any trace of true outer ramus. The jointed limbs of myriapods and hexapods could, arguably, have been derived from lobopodial limbs essentially resembling those of the extant Onychophora, and these limbs could have been derived from limbs of metamerically segmented worms with a haemocoel which, along with the muscles, worked the uniramous limbs. As long ago as 1940, Tiegs[8,9] emphasised the unity of these three taxa and Anderson[10] has shown in detail the common ontogenetic theme which exists throughout the Uniramia and contrasts absolutely with that pervading the entire crustacean group. Further, crustecean ontogeny could not have been derived from that of any known annelidan group. In contrast, the uniramian ontogeny might have been derived from that of some yolky-egged annelid or annelid-like worm which possessed a haemocoel and lobopodia, but not coelomate parapodia.

There is no justification on the basis of Golgi phenomena for the restriction of the term Uniramia to the Myriapoda and Hexapoda alone, nor for the exclusion from the arthropods of any animal on one character alone. That the Onychophora are thoroughly arthropodan is shown by their cuticle[11,12], which contains protein and chitin, but not collagen, in contrast to annelids; by the presence of an ecdysial cycle as in other arthropods[13], the cuticle being shed in one piece, as in no other invertebrates on Locke and Huie's list[1]; and by the general anatomy of the Onychophora, which tallies with that of other uniramian taxa. We do not know the significance of onychophoran Golgi phenomena nor of its association with unstriated muscle, but this one feature is no acceptable reason to disrupt the Uniramia or exclude the Onychophora from the arthropods.

Thus, without further consideration of the several other arthropodan taxa, it is clear that the Uniramia and Crustacea each represent well defined arthropodan taxa, which could not have originated from common annelidan ancestry, and that their cuticles must have evolved in parallel.

The exoskeleton of all arthropods has the same mechanical functions in providing unstretchable cuticles, sclerites and arthrodial membranes concerned with trunk movements and muscle insertions. The requirements of other invertebrates are different. The cuticles of the various arthropodan taxa are not identical, although protein and fine-fibre systems form the basis of most sclerites. There is thus no reason that the general manner of formation of arthropod cuticle may not have evolved more than once; nor is there any sound evidence against the unity of the Uniramia or against a polyphyletic concept of arthropodan evolution.

Are viroids negative-strand viruses?

In their paper detailing the complete sequence of 359 bases in potato spindle tuber viroid (PSTV) RNA, Gross *et al.*[1] considered, as have other workers[2], that the circular single-stranded molecule is unlikely to function as a messenger RNA. The possibility that PSTV RNA might be a non-coding strand rather than a positive (coding) strand may have been overlooked.

I have examined the base sequence complementary to that established by Gross *et al.*[1]. Four possible initiation triplets (all GUG) and six possible strong termination triplets could result in four polypeptides containing 108, 79, 43 or 28 amino acids, of which the two larger (with molecular weights (MWs) 11,300 and 8,500) are the more interesting. The longest of these sequences begins with a GUG at positions 134–136 and teminates at a double UAG at positions 99–104 (Fig. 1). The GUG is preceded by a well-placed potential ribosome recognition sequence as indicated in Fig. 1. The second potential polypeptide is in a different reading frame and begins with a GUG at residues 177–179. It is preceded by an unbroken sequence of 14 purines, and teminates in an UAG at residues 55–57. The amino acid composition of the small polypeptide is unremarkable except for a high content of phenylalanine (10%), but the larger polypeptide has a content of arginine (11%) and lysine (5%) that would give it histone-like properties.

Two experimental observations would fit with the view that one or both of these polypeptides are produced by viroids. First, there is evidence for an RNA strand complementary to citrus exocortis viroid (CEV) RNA in infected tissues[3]; CEV is fairly closely related to PSTV[2]. Some of the hybridisable RNA was in the nuclear fraction but more was in the soluble cytoplasmic fraction, where it might have possessed a messenger function.

Second, an increase in amount (and in radioactive labelling) of two polypeptide bands in polyacrylamide gels was found in CEV-infected plants[4]. MWs assigned to the two polypeptides were 18,000 and 15,000. I have recalculated these MWs as 13,200 and 10,400, using as internal markers the large and small subunits of ribulose-1′,5′-diphosphatecarboxylase (MWs 54,000 and 12,000). The larger of the CEV-induced polypeptides was located preferentially in the histone fraction, the smaller was in the non-histone fraction[4]. This partitioning fits with the amino acid composition of the two polypeptide components that could be derived from the negative strand.

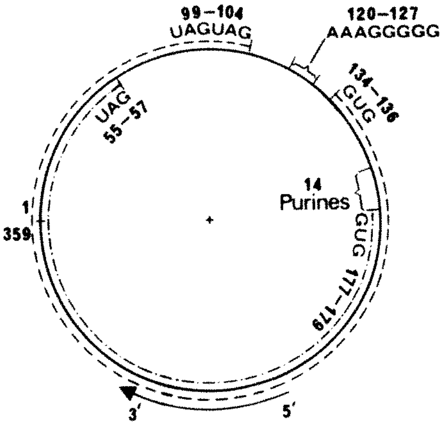

Fig. 1 Model of a PSTV RNA strand complementary to the viroid strand sequenced by Gross *et al.*[1]. The heavy line represents the circular RNA. The numbers 1 and 359 indicate the same start position as that used by Gross *et al.*, but because the strand represented here is antiparallel to the viroid strand, the position of base 1 in this diagram is equivalent to that of base 359 in the viroid sequence. Dashed line, polypeptide of MW 11,300; dotted-dashed line, polypeptide of MW 8,500.

In the light of the above evidence I suggest that viroids may be very small negative-strand viruses with the following properties. (1) They use secondary structure rather than a protein coat for protection of the genome; (2) they use a host polymerase to make a complementary RNA strand; and (3) this strand serves as a template for progeny viroid particles and as message for one or two viroid proteins. This hypothesis can be tested by a search in PSTV-infected tissues for one or two viroid-induced polypeptides of the predicted size and composition.

New Journals
Prices include postage

Journal of Family Therapy

Editor: Christopher Dare

Publication: Quarterly from February, 1979

Subscription: Volume 1, 1979 . . . £13.00 (UK) $35.00 (Overseas)

The journal's aims will be to encourage and increase the practice and standards of marital and family therapy; to encourage research into the practice and training in the different forms of the therapies; and to provide opportunities for descriptions of treatments and training for treatment in different settings. An international board of assessors, will publish material from all over the world. The journal will seek to facilitate the integration of marital and family therapy into other treatment and case work modalities and will attempt to stimulate the development of marital and family therapy by publishing research into aspects of the normal marriage and family. It will also present abstracts of publications in fields alongside those of family therapy which are thought likely to stimulate lines of enquiry into the subject.

Media, Culture and Society

Managing editors: James Curran, Nicholas Garnham, Andrew McBarnet, Paddy Scannell, Colin Sparks

Publication: Quarterly, from January, 1979

Subscription: Volume 1, 1979 . . . £15.00 (UK) $40.00 (Overseas)

This major, new, international journal will provide an important forum for the presentation of research and discussion across the whole field of cultural practice. The main focus will be on the mass media (television, radio, journalism) within their political, cultural and historical contexts. Their relationship to literature, the visual and performing arts, photography, publishing, and to more general artistic and cultural practices is of central reference to the journal.

International Journal of the Sociology of Law

Editors: Maureen Cain (Conveiner), Kit Carson and Paul Wiles

Publication: Quarterly, from February, 1979

Subscription: Volume 7, 1979 . . . £15.90 (UK) $42.50 (Overseas)

The *International Journal for the Sociology of Law* is successor to the *International Journal of Criminology and Penology*. Over recent years sociologists of crime and deviance have come to realise that their work must be enriched by placing it in the broader context of the study of social control. The new journal links this concern with the rapidly developing fields of the sociology and anthropology of law. The new journal adopts a sociological and anthropological approach rather than the inter-disciplinary one which has characterised criminology. Because of this it will be of interest to sociologists and anthropologists who are not specialists in the substantive field.

The Journal of Infection

The Journal of the British Society for the Study of Infection

Editor: Dr. Hillas Smith

Publication: Quarterly, from March, 1979

Subscription: Volume 1, 1979 . . . £16.00 (UK) $42.50 (Overseas)

Infection, resulting from the interaction of host and microbe, is found in a multitude of different forms, both in man and animals. The journal will reflect this diversity as the editorial policy is to publish papers not only on clinical infection in man and animals, but also on microbiological, immunological, therapeutic, epidemiological, haematological and statistical aspects of the subject. From time to time there will be an in-depth study of a special topic in infection. There will also be book reviews and a correspondence column.

The New Phytologist

Editors: D. Briggs, J. H. Burnett, J. L. Harley, D. H. Lewis, L. Leyton, D. C. Smith, P. J. Syrett, R. G. West

Publication: Bi-monthly

Subscription: Volumes 82-83, 1979 . . . £44.00 (UK) $118.00 (Overseas)

The editorial policy is to publish papers on all subjects connected with plant science, whether short reports, full-length papers or book reviews. *The New Phytologist* has traditionally been a forum for important articles bridging the gap between the different subdivisions of the subject. The journal is essential reading for all botanists.

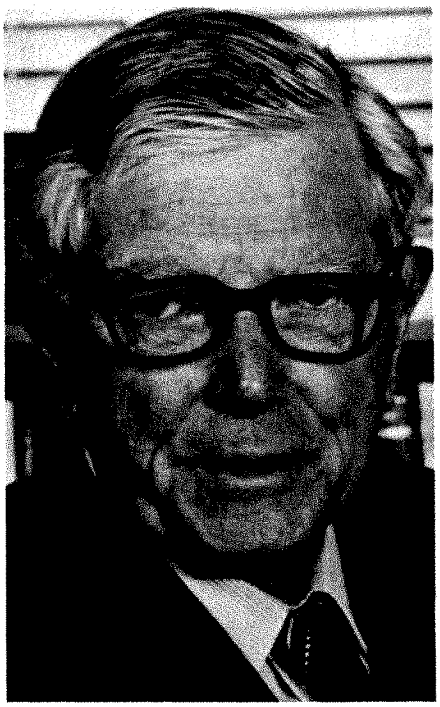
Thoughts on ageing

A. J. S. Davies

Endurance of Life: Implications of Genetics for Human Life. By Macfarlane Burnet. Pp. 230. (Cambridge University Press: Cambridge and London, 1978.) £8.95.

PERHAPS the best of this new book of Burnet's is the information it gives about the man himself and the relationship he has to the society in which he has become famous. Burnet states that one of the reasons that he writes is to try to clarify his own mind. In this instance the supposed topic for elucidation is ageing—not surprisingly somewhat of an obsession at the age of 78. In fact the book is a collection of essays, of variable quality, loosely related by their common authorship but little else. Aside from the need for self-expression Burnet also senses that as an eminent man his book may well be read by others, some of whom will be laymen. His concessions to the non-scientist are, however, by no means uniform. Diagrams of childlike simplicity are followed by pages of relatively unexplained and sometimes unrelated complexities, and I believe it highly unlikely that any but the most dedicated non-scientist will persevere with the book—which is a pity. Science is greatly in need of expositors of its meaning and basic facts.

Burnet's approach to human affairs is essentially that of a rationalist. He believes that there are facts of life which are not widely recognised, perhaps because of their unpalatability, but which nevertheless should be given wider public airing. As a geneticist Burnet of course espouses the basic assumption that that which is perceived of an organism, its phenotype, arises as a consequence of an interaction between the genetic information encoded in the DNA, the genotype, and the environment. He is unimpressed by those who suppose that whereas this is all right for sweet peas and field-mice it is a gross over-simplication for *Homo sapiens*. Burnet's stance in this old nature versus nurture argument is resolute. He believes that such human characteristics as intelligence and aggression must have a strong genetic component, despite the fervent hopes of educationalists and politicians alike that this is not so.



Sir Macfarlane Burnet

Contemporary society, according to Burnet, has a residue of activities, largely genetically determined, which were of advantage to the human species in the hunter-gatherer eras but for which the role has become less clear with the urbanisation and industrialisation of the past 10,000 years or so. A variety of social problems such as juvenile delinquency and the ennui of high rise flats (apartment blocks) seem to fall into perspective against such a back drop.

Statements of determinism have of course been made before, notably by Darlington. In Burnet they have engendered a massive pessimism arising perhaps from impotence at not knowing what to suggest if they are valid. Whatever the truth, the argument is a good one and is presented with a force which belies the years of the author.

Not content with a viewpoint which will antagonise almost every sociologist in the world, Burnet also points to the genetical homogenisation which he believes to be occurring in the middle echelons of society which could act to diminish human diversity to an undesirable degree. Reduction in family size he notes may prevent overpopulation but it will also disturb a natural balance which involved much natural selection within larger families. Burnet has also taken to heart the argument that one of the less desirable outcomes of modern medicine is the increasing preservation of the genetically unfit.

Burnet stops more or less short of the conclusions of the pre-war eugenicists but he nevertheless feels strongly that genetic counselling is worthwhile. He also believes severely handicapped children might well not be given the life support that they require.

He is an elitist who sees harm in differential breeding rates in the community which sometimes seem to favour the increase in the size of the populations of the under-privileged, but again he has no specific recommendations to make. His arguments are not in the main supported by an adequate bibliographical background but their emotional content is clear. Burnet sees himself as speaking with a common sense voice for the majority of intelligent men and women.

There are in the book many paradoxes. Burnet seems to equate power with evil on the basis of a definition of power as influence over people but he fails to realise that he himself is an extremely powerful and influential person but probably not evil. Goodness seems to be largely a feminine characteristic, a viewpoint which ought to make the more militant female liberationists fume.

The least satisfactory of the essays are those concerned with ageing. Briefly, Burnet sees ageing as due to the accumulation of genetic errors within somatic cells. Particularly important are errors in the error-rectifying system, which should have far more disastrous consequences than more mundane coding alterations. Burnet accepts all evidence for his theory but often seems disinterested in what scientists call the null hypothesis. He even has the face to criticise the virologists (p 39) for apparently adopting a similar attitude. Indeed Burnet's hostility to viruses borders on the irrational in that he seems unable to envisage that one of the genetic errors in somatic cells which he invokes so freely might in fact be the incorporation of a viral genome.

There is a whole chapter on *Xeroderma pigmentosum* which is seen, perhaps correctly, as a condition in which a deficient error repair mechanism leads to a variety of defects including a high susceptibility to ultraviolet light and increasing numbers of skin tumours. Burnet sees this unpleasant syndrome, which has a known genetic basis, as a grossly accelerated example of ageing corresponding exactly to his hypothesis. In addition the belief he has about cancers arising as a consequence of somatic mutations is confirmed. To one who has read a number of Burnet's previous books much of the early parts of the present volume may evoke a strong sense of *déjà vu.*

As, with succeeding chapters, Burnet moves from Ageing in Mammals by way of the Genetics of Power to his Vision of a Million Years the book becomes more readable. Those who wish to dip into it should in my opinion start at the back and work forward until they come to familiar ground. The most evocative and fluent passages are those which concern Burnet himself. He talks wistfully of societies in which privileged elders can retain an honoured position as men of experience and transmitters of traditional wisdom. Despite or perhaps because of this he makes statements of astonishing lack of insight—for example, "a little thought will convince most people that natural death means a death in which the essential factors concerned were genetic ones" The value judgment involved here in the use of the adjective essential and the apparent lack of realisation of the operation of the many stochastic events which could influence the matter are surprising.

Whenever he himself has not thought about a particular matter it is dismissed in a lordly manner—for example, "we need not worry too hard to imagine by what mechanism it ('psychosomatic' death may be achieved."

Few aspects of our contemporary society escape Burnet's pessimistic pen. Most of his views will be unpopular and one cannot help but agree with his statement that he has never failed to write, or modify what he has written, out of fear of the consequences. The book is erratic, aggravating, pontifical on occasions, sometimes clumsy, often obscure. but rarely dull It should be read and discussed ☐

A. J. S. Davies is Head of the Biology Division at the Chester Beatty Research Institute, London, UK.

Atomic and molecular physics

Atoms and Molecules. By M. Weissbluth Pp.713. (Academic: New York, San Francisco and London, 1978.) $59.50; £38.65.

GROWN out of a full year graduate lecture course in atomic and molecular physics, this monograph is both a textbook and a reference manual of ambitiously wide scope. Thus the final chapter (28) on ligand fields treats such topics as electronic d^2 in a cubic field with spin-orbit coupling. And the chapter's last section concludes with a diagram that shows the energy levels of molecular orbitals when an octahedral complex AB_6 is involved; from a preceding table follows, for each symmetry associated with the levels, the structure of symmetry adapted orbitals for both the orbitals of the central atom A and the ligands B. It would be only a short step to frontier problems such as ferric ions in proteins. Derivations often take just a few lines—try this conclusively without simultaneously applying group theory to the central electrons and the lattice-like structure around them! All the required atomic and algebraic tools and data are lucidly expanded in the book, and referencing to them is done efficiently.

Naturally group theoretical topics take up most of the space in the first of the text's six parts, which gives the mathematical background. Only rigorous pruning to the needs of atomic and molecular physics, and resorting to summaries of selected properties where appropriate, keeps this part in size and readable. He who struggled through the thicket of the full representation theory of the permutation group, this centrepiece in problems involving identical particles, will appreciate the refreshing brevity and swiftness with which the relevant steps in Young's scheme evolve.

Part II, on the quantum-mechanical background, assumes some undergraduate course knowledge. The remaining four parts move on towards molecules: one-electron atoms (from Dirac's equation by way of Schrödinger's to hyperfine interactions), N-electron atoms, electromagnetic interactions (culminating in the Kramers-Heisenberg formula and in applications), and finally 130 pages on molecules, covering in particular the spectra of polyatomic molecules The notion of conjugate configuration, in the context of N-electron problems, tells immediately why no spin-orbit splitting occurs for half-filled shells. However, even then the mutual effect between electrons does give rise to some splitting. Such splitting may be ignored because of its smallness, though the author, in this rare instance, misses the cause when relating it to interaction solely between terms. All except purists are likely to overlook an unnecessary impediment to more fundamental approaches in some basic relationships: to equivalence a unit vector directly with its cartesian representation as a column matrix, and on occasion a state vector with the complete function—something quite commonly found in textbooks Despite these shortcomings the whole presentation is elegant and informative.

This new book shares one weakness with many a first edition: the index doesn't measure up to the text. Similarly, the references haven't quite outgrown a list for the students of recommended reading. There is one particular omission: among the three classics on group theory and quantum mechanics, which came out within a very short period around 1931, H. Weyl's and E. Wigner's books are mentioned, whereas B. L. van der Waerden's is not.

Who is going to buy the book? Sadly enough the price tag will turn away most graduate and postgraduate students. Needless to say that the book is well produced and the typographical layout excellent. But perhaps one should draw attention to over 70 useful tables, an impressive collection of information which, leaving aside the newly compiled tables, one might as well find scattered across several book-shelves.

Werner Elssner

Werner Elssner is Temporary Senior Lecturer in the Department of Physics and Astronomy at University College, London, UK

LKB Ampholine.®

Your standard in electrofocusing.

LKB Ampholine® carrier ampholytes form superior linear and reproducible pH gradients, for optimal separations and accurate pI determinations.

They have very high buffering capacity and conductivity. UV absorbance at 280 nm is so low that you can detect proteins without removing them from the pH gradient.

Ampholine has only amino and carboxyl functional groups, to limit binding possibilities with proteins; you can easily separate Ampholine and proteins, but this is not always necessary even for enzyme assays.

Besides the large selection of Ampholine pH ranges available, you can make other ranges simply by mixing one Ampholine carrier ampholyte with another.

LKB offers the complete system for electrofocusing: Multiphor, LKB 2103 Power Supply, Ampholine® and Ampholine® PAGplates — your standards in electrofocusing. All supported by LKB Application Notes and *Acta Ampholinae* Literature Reference List.

For more information write to LKB: the only complete source of experience, knowledge and equipment for electrofocusing. LKB Produkter AB, S-161 25 Bromma, Sweden.

LA TROBE UNIVERSITY
Melbourne, Australia
School of Biological Sciences
DEPARTMENT OF BIOCHEMISTRY

RESEARCH FELLOW

The appointee will participate in a project on "The biosynthesis of polysaccharides and polysaccharide-proteins in higher plants" with the chief investigators, Professor B. A. Stone and Dr G. B. Fincher. This project is funded by the Australian Research Grants Committee.

The Research Fellow is expected to have considerable experience in membrane isolation, fractionation and characterisation. Further experience in the areas of polysaccharide, glycoprotein or proteoglycan biosynthesis or characterisation would be advantageous but not mandatory.

The position will be for one year initially, although possible extension to two or three years may be approved after appointment. A travel and removal allowance will be paid.

Qualifications: A Ph.D. in Biochemistry or a cognate discipline.

Salary: A starting salary of $A15,179 per annum, with a range of $15,179 to $16,540 if the appointment is extended over three years.

Commencement date: As soon as possible.

Further information and application forms are available from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF. Applications close on **January 27, 1979.** 8919(A)

HARVARD SCHOOL OF PUBLIC HEALTH

The Harvard School of Public Health welcomes applications for a tenured Professorship in the biomedical sciences in the Department of Nutrition. The candidate is expected to head the Department, which has post-doctoral, doctoral, and Master's students, substantial laboratory space and some endowment. The University is committed to integrate the activities of its various faculties in both research and teaching, and this senior level person would be expected to forward these goals in the nutritional sciences, particularly as they relate to public health problems. Broad qualifications for the position might typically include a Ph.D. and/or M.D. degree; a distinguished record of biomedical research relevant to or involving nutritional sciences; ability to teach nutrition-related graduate courses, and to attract promising students and junior faculty to the field; leadership, administrative experience, and interdisciplinary orientation which includes an interest in health policy issues.

Send curriculum vitae, a list of publications, a statement of current and future interests in nutritional sciences, and the names of two individuals who would be willing to respond to a request for evaluation to:

Mrs. Emily Morrison

COMMONWEALTH MYCOLOGICAL INSTITUTE
FERRY LANE, KEW, SURREY

Vacancies for

FOREST MYCOLOGIST and PLANT PATHOLOGIST

THE FOREST MYCOLOGIST will work on the fungal pathogens of Central American pines, in a post funded by the UK Ministry of Overseas Development, for a period of three years.

The successful candidate will be based at the Commonwealth Mycological Institute, but will be required to make annual collecting visits to Central America to survey and collect fungi associated with pines.

Qualifications: A good honours degree with postgraduate experience involving work on the identification of fungi. Experience in forest pathology will be an advantage.

THE PLANT PATHOLOGIST will work as a Liaison Officer under the UK Ministry of Overseas Development, based at the Commonwealth Mycological Institute.

He will assist developing countries on behalf of ODM with the identification of pathogens of forest trees; advise on control methods and supply information of current interest on forest pathology; conduct short-term surveys and make advisory visits overseas. He would be expected to contribute to the work of the Commonwealth Mycological Institute.

The post forms part of a small team comprising two Liaison Officers and two ancillary staff.

Qualifications: Preference will be given to a forest pathologist with knowledge of plantation problems. Tropical experience is essential.

Salary, FOR BOTH POSTS, in the scale £2,839 to £8,461 (which is subject to revision). Starting salary according to age, qualifications and experience.

Application forms, and further particulars, obtainable from: The Executive Director, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN.

Closing date for applications: February 12, 1979. 8844(A)

UNIVERSITY OF WARWICK RESEARCH FELLOW

Synchrotron Radiation Instrumentation

In the Department of Engineering to work with Dr D. K. Bowen on the design, construction and use of a computer-controlled X-ray topographic camera for use at the synchrotron radiation source under construction at S.R.C. Daresbury Laboratory.

Salary up to £4,382 per annum on the Range IA scale £3,883 to £6,555 per annum (under review). The post is tenable for three years, starting as soon as possible.

Application forms and further details from the Academic Registrar, University of Warwick, Coventry CV4 7AL. Closing date for receipt of applications January 15, 1979. Please quote reference 20/A/78. 8899(A)

NATURE CONSERVANCY COUNCIL

Senior Scientific Officer/ Principal Scientific Officer

SALARY SCALES

Senior Scientific Officer	**£5,154 to £6,898**
Principal Scientific Officer	**£6,609 to £8,461**
Plus Inner London Weighting	**£465 per annum.**

Applications are invited for the post of Senior Scientific Officer/Principal Scientific Officer in the N.C.C's Land Division.

The Land Division of the Nature Conservancy Council is based in London and headed by the Chief Land Agent. The Division is responsible to the Director, N.C.C. for Council's professional land agency and estate management throughout Great Britain.

THE POST

The successful candidate will be responsible for providing a specialist advisory service on land use economies and to monitor innovations and trends in commercial land use to assess the effects these may have on nature conservation. Principal duties will include examining and reviewing existing N.C.C. land management policy, maintaining an awareness of research into land use practices, and the dissemination of such knowledge to officers throughout the N.C.C.

AGE AND QUALIFICATIONS

Candidates should have a first or second class honours degree, or equivalent, in biology, botany, zoology, geology or geography and should also have subsequent training in agriculture or forestry with experience in, and knowledge of rural land use.

Senior Scientific Officer: Candidates must be at least 25 and under 32 years of age and have at least four years' relevant postgraduate experience.

Principal Scientific Officer: Candidates should normally be between 30 and 50 years.

Application forms and further details are available from Recruitment Section, Nature Conservancy Council, Godwin House, George Street, Huntingdon, Cambs., PE18 6BU (Tel. 0480-56191). Closing date for completed application forms is February 16, 1979. 8869(A)

SHEFFIELD AREA HEALTH AUTHORITY (TEACHING)
Centre for Human Genetics

CYTOGENETICISTS

There are immediate vacancies for two Cytogeneticists (Basic Grade) at the above unit. The work is part of a Regional diagnostic service and will include tissue culture and the identification of chromosome abnormalities. Applicants should have a relevant Science degree.

Salary Scale £3,486 rising to a maximum of £4,899. For further information telephone Sheffield (0142) 667333.

Applications giving details of age, qualifications and experience, with the names and addresses of two referees to: the District Personnel Officer, Floor B, Hallamshire Hospital, Glossop Road, Sheffield S10 2JF.

8880(A)

Graduate Biologist

Fungicide Screening

Chesterford Park Research Station is the Research and Development centre for the Agrochemical Division of Fisons Limited. We are looking for a graduate biologist to join the Fungicide Screening Team in the Biological Screening Department.

As a Scientist II you will supervise the work of two Research Assistants and participate in the laboratory evaluation of new compounds for their fungicidal (in-vitro only) and bacterial activity against plant pathogens.

This position will be suitable for a first degree graduate with an interest in, and preferably some practical experience of, working with plant bacterial diseases.

We offer a competitive starting salary and the substantial range of benefits associated with working for a major industrial company, including relocation expenses where appropriate.

For full details and an application form please write to or telephone: Roger Lake, Personnel & Training Officer, Fisons Limited—Agrochemical Division, Chesterford Park Research Station, Saffron Walden, Essex. CB10 1XL. Telephone: Saffron Walden 23542.

GRANTS FOR BASIC RESEARCH:

New Approaches to Tropical Diseases

The Special Programme for Research and Training in Tropical Diseases is encouraging research into the problems of tropical diseases Its Biochemical Sciences Scientific Working Group has limited funds available for research proposals on basic mechanisms of parasitism in malaria, schistosomiasis, filariasis, trypanosomiases, leishmaniases and leprosy. The following areas have been defined as particularly relevant·

- —Parasite-host cell recognition and intracellular interactions
- —Identification of changes in the membrane of parasitised cells.
- —Isolation of parasite mutants and variants modified with respect to infectivity and/or pathogenicity.
- —Fractionation of parasites for the purpose of isolation of antigens and other molecules
- —Identification of host genetic factors which modify infection and influence the development of parasitic disease, including methods for HLA typing applicable under field conditions.
- —Elucidation of the activities of eosinophils and basophils in metazoan parasitic infection

However, proposals in other topic areas offering insights into the basic mechanisms of parasitism are also welcome.

The research proposals should be relevant to improved control of the six diseases of concern to the Special Programme Model systems elucidating these diseases or their pathogens will also be entertained

Enquiries and requests for research proposal forms should be addressed to.

Office of the Director
Special Programme for Research and
Training in Tropical Diseases
World Health Organisation
CH-1211 Geneva 27, Switzerland

Deadline for receiving the current cycle of applications is 15 April, 1979. 8935 (A)

UNIVERSITY COLLEGE OF SWAZILAND

Applications are invited for the post of LECTURER IN THE DEPARTMENT OF CHEMISTRY

Candidates should possess a Ph D in Chemistry with specialisation in Physical Chemistry Candidates with qualifications in inorganic chemistry will also be considered. The appointee will be concerned with first and second year teaching in the subject, with the possibility of third and fourth year teaching from 1980 onwards There will also be opportunities for research.

Salary scales· Lecturer I E5,940 to E7,860 per annum (£1 sterling=E1 68) Salary scale and entry point according to qualifications and experience. The British Government may supplement salary in range £1,650 to £2,184 per annum (sterling) for married appointee or £480 to £960 per annum (sterling) for single appointee (currently under review and normally free of all tax) and provide children's education allowances and holiday visit passages Short-term contracts for two or four years If appointment is for a limited period, a 25% gratuity is paid in lieu of superannuation for the first two years of service, 27½% for the second two years. A 10% inducement allowance is payable to expatriates not qualifying for supplementation from other sources. Family passages, education allowance for expatriates, free ordinary medical attention at Government institutions, accommodation at reasonable rental; biennial leave

Detailed applications (two copies) with curriculum vitae and naming three referees should be sent to the Registrar, University College of Swaziland, Southern Africa, by January 22, 1979. Applicants resident in the U K should also send one copy to the Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT Further details may be obtained from either address. 8923(A)

THE ROWETT RESEARCH INSTITUTE

Bucksburn, Aberdeen AB2 9SB

BIOMETRY DEPARTMENT

A vacancy exists for a Scientific Officer or Higher Scientific Officer. The principal duties are to participate in the development of the data-acquisition and processing system, based on an IBM system 7 and an IBM 1130 computer, to advise and assist members of the scientific staff in writing and running their programmes, and in the statistical analysis and interpretation of their experiments. Knowledge of Fortran IV and Assembler, together with some experience of an IBM 1130 or similar computer, an advantage

Candidates should have a first or upper second class honours degree in Computing Science.

The appointment will be as Scientific Officer (Salary £3,294 to £4,415 per annum) or Higher Scientific Officer (£4,101 to £5,448), grade and starting salary depends on experience At least two years' relevant post-graduate experience is required for Higher Scientific Officer grading.

There is a non-contributory pension scheme.

Further details of the post may be obtained from the Secretary of the Institute, to whom applications should be submitted together with the names and addresses of two referees. Closing date January 19, 1979 8875(A)

THE UNIVERSITY OF LIVERPOOL

HEATH HARRISON CHAIR OF ORGANIC CHEMISTRY

Applications are invited for the Heath Harrison Chair of Organic Chemistry.

The salary will not be less than £9,865 per annum and initially will depend on the qualifications and experience of the successful candidate.

Applications (12 copies), together with the names of three references, should be received not later than January 26, 1979, by the undersigned, from whom further particulars may be obtained (Candidates overseas may send one copy only by airmail). Quote Reference RV/427/N.

BIOPHYSICIST

A tenure track position will be available in Biophysics at the University of Illinois effective Fall 1979 The position is expected to be at the Assistant Professor level

It is anticipated that the successful applicant will carry out research and teaching in biophysics, in the general area of biomolecular structure Candidates should have a Ph D degree and some postdoctoral experience Salary is negotiable.

Please send your curriculum vitae by March 1, 1979, to Dr A. R Crofts, Chairman of Biophysics, 524 Burrill Hall, University of Illinois, Urbana, IL 61801 (Tel 217-333-7407)

The position is conditional upon continued availability of funds. **An Equal Opportunity and An Affirmative Action Employer** 8902(A)

PAISLEY COLLEGE

RESEARCH ASSISTANT

PHYSICS DEPARTMENT

This is an S R C funded R.A 1B post involving the dynamic measurement of oil film thickness in tribology by neutron scanning using an image intensifier. The project will involve work at the East Kilbride S U R R C nuclear reactor facility and is in collaboration with the National Engineering Laboratory.

Applications are invited from post-doctoral or experienced postgraduate engineers/physicists The initial contract will be for two years, at a salary in the range £3,500 to £4,000 per annum

Applicants should write to Dr. A. R Spowart, Senior Lecturer, Physics Department, Paisley College of Technology, High Street, Paisley PA1 2BE, attaching a curriculum vitae with the names of two referees, by February 28, 1979. 8903(A)

WESSEX WATER AUTHORITY
REGIONAL BIOLOGY UNIT

MARINE BIOLOGIST

£4,635—£4,962 per annum including supplement plus car allowance

Applications are invited for the above post within the Regional Biology Unit at the Regional Biology Laboratory, Corfe Mullen, near Wimborne, Dorset

Duties include organising and carrying out routine Marine Biological Monitoring and special Marine Biological investigations of Estuaries and Coasts, the two coastlines of the Wessex Water Authority area, and also involve working at sea on the Authority's research vessel.

Applicants must be suitably qualified Marine Biologists and ideally should have experience of Marine Monitoring it would also be an advantage to be an experienced Sub-Aqua Diver Applicants must also hold a current driver's licence.

A regular car user allowance will be paid, together with re-location expenses where applicable.

Application forms and job description, quoting reference number 362/54 are obtainable from Mr T Pleass, Personnel Officer, Wessex Water Authority, Wessex House, Passage Street, Bristol (telephone Bristol 290611 Ext 229) and should be returned no later than 16th January 1979 8915(A)

Wessex Water

NEW SOUTH WALES STATE CANCER COUNCIL

SPECIAL UNIT FOR INVESTIGATION AND TREATMENT

BIOMETRICIAN

The Special Unit of the New South Wales State Cancer Council, situated at the Prince of Wales Hospital, Sydney, Australia, requires the services of a biometrician to take charge of statistical aspects of the activities of both the Council and the Special Unit Of special interest is the organisation and interpretation of clinical trials, laboratory results, population surveys and the medical records of cancer patients

At present, statistical assistance is provided by a senior consultant, and it is expected that this relationship will be maintained and fostered Facilities currently available within the Unit are a time sharing facility via a DIABLO 1620 console linked to a CYBER 72 CDC at the University of N S W., and a small WANG 2000 computer.

The position requires someone with a good personality and a high degree of initiative. Postgraduate qualifications are essential and practical experience in statistics and computing is desirable

Salary will be that of a Senior Scientific Officer ($16,686 to $20,409) Conditions of employment in accordance with Scientific Officers (Public Hospital Scientists) Award

Applications should contain full details of personal background, qualifications and experience, and, where appropriate, a curriculum vitae

Further information may be obtained from Dr A R Nash, Special Unit, Prince of Wales Hospital, Randwick, Australia 2031 Written applications to be forwarded to above address 8917(A)

DEVELOPMENTAL BIOLOGIST

Applications are invited for a faculty position to begin September, 1979 Candidates should have Ph D in appropriate field and postdoctoral experience Rank and salary are open

Duties include teaching at undergraduate and graduate levels and development of a vigorous research programme.

Send curriculum vitae, statement of research plans, copies of publications, and arrange for three letters of recommendation to be sent by January 15, 1979 to.

Professor G M. Happ,
Department of Zoology,
University of Vermont,
Burlington, Vermont 05405

An Affirmative Action Employer

THAI NATIONALS

POSTDOCTORAL POSITION

of two-year duration available immediately for sequence and affinity labelling studies on ribulosebisphosphate carboxylase at salary of $12,000 for first year

Please send resume and letters of references to. Dr Fred C Hartman, Oak Ridge-University of Tennessee Graduate School of Biomedical Sciences, P O Box Y, Oak Ridge, TN 37830 *An Equal Opportunity/Affirmative Action Employer.* 8908(A)

CSIRO

AUSTRALIA

Postdoctoral Research Fellow

Division of Irrigation Research Griffith, NSW

CSIRO has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 7,000 employees —2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia

Field: Plant Nitrogen Studies

General The Division is located at Griffith, about 600 km north of Melbourne and 650 km west of Sydney. Griffith has a population of about 13,000 and is situated in a well-developed rural centre, with good educational and extensive recreational facilities. The Division's research encompasses a wide range of disciplines within the context of irrigated cropping, including studies on soil-root zone biology and environmental plant physiology and biochemistry

Duties: To join a research group concerned with metabolic factors which limit the efficiency of nitrate utilisation by crop plants The work will relate to how plants integrate biochemical fluxes of carbon and nitrogen metabolites so that some experience with isotopic technique (^{14}C and ^{15}N) would be an advantage.

Qualifications A Ph.D degree or equivalent qualifications in plant physiology or biochemistry Experience with ^{15}N techniques would be an advantage.

Salary: Research Scientist or Senior Research Scientist A$14,829—$A21,543 p.a.

Tenure: A fixed term appointment of three years.

Applications IN DUPLICATE, stating FULL personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 500/345 should reach.— The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, LONDON WC2R 3EH by 31st January 1979

Applications in U S A. and Canada should be sent to:—The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W , WASHINGTON, D C , 20036, U.S A.

8929(A)

AN FORAS TALUNTAIS

Requires a

GRADUATE IN BIOCHEMISTRY, FOOD SCIENCE or VETERINARY SCIENCE

For up to 3 years to undertake a project funded by the Pig Industry, involving research on the measurement of quality in Irish Pigmeat.

ESSENTIAL

Either, an Honours University degree, or equivalent, in Biochemistry, Food Science, or a related discipline OR a degree in Veterinary Science or equivalent.

DESIRABLE:

A higher degree and/or suitable research experience preferably in the Food Industry

Application form and further particulars may be obtained from the Personnel Department, An Foras Taluntais Headquarters, 19 Sandymount Avenue, Ballsbridge, Dublin 4 ('Phone Dublin 688188). Latest date for receipt of completed forms, Monday, January 22, 1979. 8934(A)

OVERSEAS DEVELOPMENT

KNOW-HOW: vital to developing countries

Agronomist/ Crop Protection SUDAN

To work as part of a Food Crop Development Team within the Project Development Unit of the Regional Ministry of Agriculture, Juba. Specific responsibility for 1. Identification of major pests diseases and weeds of economic importance in the Southern Region. 2. The conducting of field trials aimed at control of pests, diseases and weeds in crops. 3. Screening of local and imported plant material for pest and disease resistance. Applicants aged 25-35 years should have a degree in agriculture and at least 3 years experience, preferably overseas in agronomy and crop protection.

Appointment 2 years. Salary (UK taxable) in range £4,100-£7,500 p.a. plus tax free overseas allowance in range £2,145-£4,725 p.a. (Ref. 331X).

The post is wholly financed by the British Government under Britain's programme of aid to the developing countries. In addition to basic salary and overseas allowances other benefits normally include paid leave, free family passages, children's education allowances and holiday visits, free accommodation and medical attention. Applicants should be citizens of the United Kingdom.

For full details and application form please apply, quoting reference stating post concerned, and giving details of age, qualifications and experience to:

Advertisement for Environmental/Geomorphology—Geology Department

The Department invites applicants for a two-years renewable appointment starting September 1979. Qualifications include a Ph.D., experience in teaching environmental geology and geomorphology and willingness to participate (on rotating basis) in instructing elementary courses in marine, geo-statistics and introductory Geology. The candidate will be expected to assist in developing research programmes in Geology and teaching in the Graduate School which opens shortly. Applicants should send résumé and three letters of reference to Kuwait University, Department of Administrative Affairs, P.O. Box 5969, Kuwait. 8885(A)

Geologists &
Geophysicists

Oil and Gas Exploration in Ira

OSCO — The Oil Service Company of Iran, a consortium of 14 international oil companies, is engaged in a major hydrocarbon exploration and development programme on behalf of the National Iranian Oil Company.

In order to accomplish this task we seek to strengthen our team of senior professionals by making the appointments detailed below.

Initial contracts 2 years. Salaries according to seniority and experience are paid in US dollars nett of Iranian income tax. Benefits include married or single status accommodation, free medical facilities, life insurance, educational assistance and a bonus on termination of contract.

Stratigraphic Group Head
c. $40,000

Responsible to the Chief Stratigrapher, you will be leading a group of specialist geologists in studies of a specific stratigraphic interval of rock in operating areas to ensure optimal exploration programmes. You will liaise closely with other specialist groups and with exploitation geologists. *(Ref T558/N)*

Area Geologist – Sub Surface
c. $40,000

To supervise and direct the exploration activities in an assigned area with the object of identifying the hydrocarbon reserves to meet offtake and capacity requirements. You will directly supervise a Project Leader and a Senior Geologist and, indirectly, the work of up to ten specialists. *(Ref T559/N)*

Project Leader – Stratigraphy
c. $36,000

Responsible for leading geological survey parties to make regional studies of the area of operation to obtain new data and to review the total geological information available and to make detailed recommendations for exploration drilling. *(Ref T568/N)*

Project Leader – Sub Surface
c. $36,000

A senior member of the team working under the direction of the Area Geologist, with the goal of finding the reserves to meet offtake and capacity requirements. You will obtain and analyse data and make recommendations for wildcat and exploration wells. *(Ref T565/N)*

$34,000 to $40,000 p.a. nett

Project Leader – Geophysics Operations
c. $36,000

Reporting to the Chief Geophysicist, you will be responsible for the planning and supervision of seismic parties, comprising field surveys, digital processing and interpretation. You will need to be able to advise on the most up-to-date field techniques. *(Ref T553/N)*

Project Leader – Interpretation
c. $36,000

Responsible to the Area Geophysicist for ensuring that proper appraisals are made of all geophysical data over all prospects and that the final compilation of maps prepared includes all pertinent geological and geophysical data. *(Ref T544/N)*

Senior Geologist –
c. $34,000

Reporting to an Area Geologist, you will be obtaining and analysing the geological data necessary for selecting and evaluating the locations for exploration wells. *(Ref T567/N)*

Data Acquisition Specialist
c. $34,000

Reporting to the Chief Geophysicist, you will act as adviser and consultant to the geophysical department on acquisition techniques and systems, so as to obtain data in the optimum manner, which after processing and interpretation will lead to a better geological understanding of the sub surface. *(Ref T566/N)*

Senior Geophysicist
c. $34,000

You will be assisting a Project Leader to plan, supervise and interpret the work of seismic contractors and preparing compilation maps for all seismic horizons of interest. *(Ref T537/N)*

Senior Geologist – Regional Studies
c. $34,000

You will be engaged in the conduct of regional studies in the area of operation and its adjacent areas by obtaining new data and reviewing existing information in the fields of stratigraphy, paleontology and related disciplines, in the search for deeper structural prospects. *(Ref T547/N)*

Candidates for these appointments must be university graduates in relevant subjects, who have had at least eight years' experience related to oil and gas exploration. Advanced degrees in specialist subjects are particularly advantageous. The preferred age range is 32-45 years.

Please write giving full details of your age, education, career history and salary progresison to date, quoting the appropriate reference number, to:

F. R. Wilcockson, Director,
Whites Recruitment Limited,
72 Fleet Street, London EC4Y 1JS.

IRANIAN OIL SERVICES LTD.

CSIRO

AUSTRALIA

Research Scientist

Division of Plant Industry Canberra, ACT

CSIRO has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: Molecular Basis of Plant Improvement

General: The Division conducts pure and applied research in molecular biology, genetics, plant breedings, genetic resources, physiology, microbiology, biochemistry, plant nutrition, ecology, crop adaptation, soil fertility and plant introduction.

This position is in a research programme concerned with the molecular basis of plant improvement. The ultimate objective being to extend the scope of plant breeding by permitting specific genetic manipulation of the plant genome.

Duties: To participate in a research programme in plant molecular biology aimed at achieving the transfer and expression *in vivo* of isolated plant genes and in examining the structure and function of plant genomes.

Qualifications: Applicants should have a Ph.D. degree in an appropriate field or postgraduate research experience of equivalent standard or duration supported by satisfactory evidence of research ability. Previous research experience in recombinant DNA methodology and in its application to the analysis of plant genomes is desirable. Preference will be given to applicants who also have expertise in plasmid genetics.

Salary: Research Scientist or Senior Research Scientist: $A14,829—$A21,543 p.a.

Tenure: Indefinite with superannuation.

Applications in DUPLICATE, stating FULL personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 130/1437 should reach:—The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, LONDON WC2R 3EH by 19th January 1979.

Applications in U.S.A. and Canada should be sent to:—The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., WASHINGTON, D.C., 20036, U.S.A.

8928(A)

DAMMAM SAUDI ARABIA

KING FAISAL UNIVERSITY

COLLEGES OF MEDICINE AND MEDICAL SCIENCES

TEACHING AND HOSPITAL APPOINTMENTS

FOR MEN AND WOMEN

The expanding Colleges of Medicine and Medical Sciences invite applications from suitable qualified men and women for teaching and teaching/clinical appointments. The curriculum follows American pattern of education, and the languages of instruction is English.

In 1979—1980 courses will cover the following subjects:

General Chemistry
Organic Chemistry
Physiology
Anatomy
Embryology
Physics
Biology
Cell Biology
Biochemistry
Pathology
Haematology
Pharmacology

Community Medicine
Epidemiology/Biostatistics
Orthopaedics
Immunology
Parasitology
Microbiology
General Surgery
Internal Medicine
Obstretrics/Gynecology
Paediatrics
Orhthalmology
Otorhinolaryngology

	Monthly salary scales in Saudi Riyals	*Approximate annual Sterling equivalents*
Professor ..	SR 7,195–9,595	£13,500–£18,000
Associate Professor ..	SR 6,435–8,185	£12,000–£15,300
Assistant Professor ..	SR 5,425–7,765	£ 9,800–£14,500

Medical Degrees attract a 30% bonus.
Hospital Duties attract a 80% bonus.
Annual home leave travel allowances are offered.
There is no income tax payable to the Saudi Arabian Government.
Free furnished accommodation is provided.
Assistance with childrens' education costs.
Interviews will be held in the United Kingdom and in the United States in late February 1979. Send a curriculum vitae to: Dr. Tawfik Tamimi, M.D., Dean

P.O. Box 2,
Sunbury-on-Thames,
Middlesex,
England.

or King Faisal University,
Saudi Arabian Educational Mission,
2223 West Loop South,
Houston, Texas 77027, U.S.A.

NIVERSITY OF LEICESTER

-RAY ASTRONOMY GROUP

OMPUTER OFFICER

k on the UK-6 and HEAO-B tell projects in the X-Ray Astronny Group. The successful candidate l be required to take responsibility the operation of the Data Terminal l to assist with writing and maintene of data analysis software for n UK-6 *and* HEAO-B projects. didates *should* be graduates in sics or Astrophysics, with experiof computer programming/ations (particularly with PDP-11 ns).

E appointment is until December (subject to satisfactory comple- a one-year probationary period), alary on the Research Assistant 1B £3,384 to £4,882.

LICATIONS in writing, with rriculum vitae and names of ferees, to Professor K. A. Department of Physics, University, University Road, LE1 7RH, by January 5.

8879(A)

UNIVERSITY OF QUEENSLAND

PHYSICAL CHEMIST/PHYSICIST/MATERIAL SCIENTIST

SENIOR RESEARCH ASSISTANT GRADE III—CHEMISTRY

Experimental work under direction on electro-deposition of semiconductor films and for testing of solar cells. Honours degree or good pass degree required. Appointment for one year with possibility of renewal.

Salary according to experience in the range $A11,667 to $A12,505 per annum. Some travel expenses could be paid.

Applications should be forwarded to the Staff Officer, University of Queensland, St. Lucia, Qld. 4067, Australia, and applicants should ask two referees to write immediately on their behalf to the Staff Officer. Quote Reference No. 43478.

8920(A)

UNIVERSITY OF BRISTOL

Applications are invited for the post of

RESEARCH ASSISTANT/ASSOCIATE

Within the Department of Anatomy. The post is tenable for up to three years and the appointee will join Profesor B. T. Pickering's group studying the biosynthesis, ultraneuronal transport and release of neurohypophysical polypeptides. Applicants should have some experience of biochemical, pharmacological, ultrastructural or immunocytochemical techniques; and be in possession of either a Ph.D. or a medical qualification.

Salary will be on the scale £3,883 to £6,555 (under review). Letters of application including curriculum vitae and the names of **three** referees should be sent to the Registrar and Secretary, University of Bristol, Senate House, Bristol BS8 1TH before January 31, 1979 (quoting ref. TLJ).

8896(A)

UNIVERSITY OF NEWCASTLE UPON TYNE

POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited for the post of S.R.C. Postdoctoral Research Associate to work on the kinetics of the coupled transport of β-galactosides and protons into *Escherichia coli.* Applicants with experience of pre-steady-state kinetics are particularly wanted but experience in the fields of membrane transport or bioenergetics would also be considered relevant. Further details may be obtained from Dr I. C. West.

The appointment will be for three years, starting as soon as possible. The starting salary will be at the appropriate point on the 1A Research Associate scale (£4,382 at age 26, under review).

Applications, including a curriculum vitae and the names of two referees, should be sent to Dr I. C. West, Department of Biochemistry, The University of Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU. 8913(A)

DIRECTOR
INSTITUTE OF MARINE RESOURCES
PROFESSOR
SCRIPPS INSTITUTION OF OCEANOGRAPHY

Senior scientist with experience in innovation investigations related to marine resources and management thereof, to lead research groups at Scripps and University of California, Davis; prepare budgets for University funds and assist in obtaining extramural funds; administer statewide Sea Grant College Program; and teach graduate students. Appointed by the President, University of California. Salary (state funded) to $44,000 for 11 months, depending on qualifications. Send vitae and names of references by 30 January 1979 to M. M. Mullin, A-008, IMR Search, University of California, San Diego, La Jolla, CA 92093. The University of California is an Equal Opportunity/Affirmative Action employer.

Please bill the University of California, San Diego, Accounting Office, Q-027, La Jolla, CA 92093, in triplicate. Reference budget No. 1655. 8893(A)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF BIOCHEMISTRY

Applications are invited from

ORGANIC CHEMISTS/ BIOCHEMISTS

for TWO POSTS of

POSTDOCTORAL SENIOR RESEARCH ASSISTANT

tenable for a period up to three years:

(A) for work on the biosynthesis of carotenoid pigments in micro-organisms. The work will involve the use of stable isotopic labelling (^{13}C and ^{2}H) and/or the development of enzyme systems.

(B) to investigate the biosynthesis and metabolism of the ecdysteroids in insects. Experience of steroid or terpenoid chemistry will be an advantage.

The appointments are tenable from a date to be arranged at an initial salary within the range £3,883 to £4,382 per annum plus U.S.S. Benefits.

Applications, together with the names of two referees, should be received as soon as possible by:

The Registrar,
The University,
P.O. Box 147,
Liverpool,
L69 3BX

from whom further particulars may be obtained. Quote Ref: RV/430/N. 8900(A)

UNIVERSITY OF MANCHESTER
DEPARTMENT OF MEDICINE

A Research Assistant is required to work on the assay of vitamin D metabolites in a research group. This is a temporary appointment for 15 months from January 1979 during the leave of absence of a member of the group. Applicants should have experience of competitive binding assay or radio-immunoassay, and should preferably hold a Ph.D. degree, but other graduates with relevant experience may be considered.

Salary ranges per annum: £3,883 to £4,382 (postdoctoral) or £3,384 to £4,382 (postgraduate).

Applications as soon as possible to Professor S. W. Stanbury, Department of Medicine, Manchester Royal Infirmary, Manchester M13 9WL. 8905(A)

SEISMIC DATA PROCESSING SPECIALIST

c $39,000 p.a. nett
Oil and Gas Exploration in Iran

OSCO – The Oil Service Company of Iran, a consortium of 14 international oil companies – is engaged in a major hydrocarbon exploration and development programme in South West Iran on behalf of the National Iranian Oil Company.

This specialist will be responsible to the Chief Geophysicist for planning and directing all seismic data processing activities, including the work of contractors' processing centres. You will act as adviser and consultant to operations geophysicists and geologists and promote an awareness of new and developing processing techniques in the industry.

You will hold a degree in Physics or Mathematics and have had at least eight years' professional experience of the practice of Geophysics, with the emphasis on seismic data processing. You will need to be able to demonstrate well developed decision-making and communicative skills.

Initial contract is for 2 years. Benefits include married or single status accommodation, free medical facilities, life insurance, educational assistance and a bonus on termination of contract. Salaries are paid in US dollars nett of Iranian income tax.

Please write giving full details of your age, education, career history and salary progression to date, quoting reference *T569/N* to:
F. R. Wilcockson, Director,
Whites Recruitment Limited,
72 Fleet Street, London EC4Y 1JS.

IRANIAN OIL SERVICES LTD. 8927(A)

BERKELEY PHYSICS

The PHYSICS DEPARTMENT of the University of California, Berkeley, expects during the next two years to be making one or two appointments at the Assistant Professor level. Preferred areas of research are astrophysics, atomic and plasma physics, condensed matter physics, nuclear physics, and particle physics, with some priority given to theoretical condensed matter physics, experimental plasma physics, and theoretical particle physics.

Applicants should write before February 1, 1979, to the **Chairman of the Physics Department, University of California, Berkeley CA 94720, U.S.A.**, giving curriculum vitae, publication list, and references. The University of California is an Affirmative Action Employer. 8867(A)

UNIVERSITY OF EXETER

A vacancy has arisen in the
DEPARTMENT OF BIOLOGICAL SCIENCES

for a Technical Grade 3 to work in Plant Physiology.

Applications are invited from persons with ONC Sciences or equivalent qualifications and normally three years' experience.

Salary £2,688 to £3,060 per annum (under review).

Letters of application giving details of age, qualifications and experience, and naming two referees should be sent to Miss Doreen B. Watson, University of Exeter EX4 4QJ, by January 12, 1979. Please quote reference No. 5106. 8870(A)

EVOLUTIONARY BIOLOGIST

Applications are invited for a faculty position to begin September, 1979. Ph.D. required in appropriate discipline (genetics, ecology, behaviour, morphology, taxonomy, physiology) and postdoctoral experience desirable. Rank and salary open.

Duties include teaching at undergraduate and graduate levels and development of vigorous research programme.

Send curriculum vitae, statement of research plans, copies of publications, and arrange for three letters of recommendation to be sent by January 15, 1979 to:

Professor G. M. Happ,
Department of Zoology,
University of Vermont,
Burlington, Vermont 05405.

An Affirmative Action Employer.
8925(A)

UNIVERSITY OF ABERDEEN

DEPARTMENT OF BIO-MEDICAL PHYSICS AND BIO-ENGINEERING

RESEARCH ASSISTANT

Applications are invited for this post in a small group working on an evaluation of properties of short-term cultures of human tumour biopsy specimens with particular reference to their chemosensitivity. Applicants should have a degree in one of the biological sciences Experience in either tissue culture or cancer research would be advantageous.

The post, funded by Cancer Research Campaign, is tenable for nine months in the first instance from January 1, 1979 Extension for a further year is likely, subject to satisfactory progress.

Salary £3,883 to £4,382 on Range 1A Research and Analogous Staff Scale, with appropriate placing

Further particulars from The Secretary, The University, Aberdeen, with whom applications (two copies) should be lodged by January 12, 1979

8887(A)

MICROBIOLOGY UNIVERSITY OF TORONTO

Scarborough College

Division of Life Sciences

Applications are invited for an

ASSISTANT PROFESSORSHIP

in the tenure-stream The applicant should have a Ph D and post-doctoral research experience in microbiology. No preference exists for any particular research specialty within the field Demonstrated ability to teach effectively across the subject area would be an important asset. Principal duties would be undergraduate teaching, participation in graduate instruction and the development of an active research programme.

The current salary floor is $16,500

The apopintment is open from July 1, 1979, and the applicant must be available to commence duties not later than September 4, 1979. Curriculum vitae and the names of three referees should be sent to Dr G. R Williams, Chairman, Division of Life Sciences, Scarborough College, University of Toronto, West Hill, Ontario MIC 1A4.

8886(A)

THE MOUNT DESERT ISLAND BIOLOGICAL LABORATORY

(M D.I B.L)

welcomes applications from established Investigators wishing to join its year-round programme.

Work at M D.I.B L has centred around problems of comparative physiology. A wide range of relevant research interests will be considered, including cell biology, environmental toxicology, developmental biology, and physiology

Independent grant support desirable. Curriculum vitae and correspondence should be addressed to:

Dr. Bodil Schmidt-Nielson,
Chairperson, Search Committee,
Mount Desert Island Biological Laboratory,
Salsbury Cove, ME 04672 U.S A

8890(A)

RESEARCH TECHNICIAN for Department of Zoology and Comparative Physiology for maintenance of research cultures of insects and assistance in research on insects nervous systems, sense organs and behaviour. Salary scale £2,688 to £3,060 per annum Reference 141/C/433 Application form from: Assistant Secretary, Personnel Office, University of Birmingham, P O. Box 363, Birmingham B15 2TT.

8884(A)

COURSES

EMBO COURSE

European Molecular Biology Organisation

Carlsberg Laboratory Copenhagen

May 7—13, 1979

Chromosome pairing and crossing-over

The laboratory exercises will consist in serial sectioning of meiotic nuclei, three-dimensional reconstructions of synaptinemal complexes from electron micrographs and analyses of the complexes by microspreading.

Demonstrations and discussions on the synaptinemal complex will involve the fungi Neottiella, Sordaria, Neurospora, Coprinus, the higher plants Lilium, Triticum and Zea, the insects Bombyx and Drosophila, the mouse and Homo sapiens Pairing with the synaptinemal complex in haploids, triploids and tetraploids, in achiasmatic meiosis, in inversions, sex bivalents and situations with large differences in crossing-over frequencies will be analysed. Lectures on the nucleosome structure and the biochemistry of meiosis will be presented The seventh day is intended to give students the possibility to acquire some of the techniques (know-how in formvar films, fixation, embedding, etc) in greater detail

INSTRUCTORS and INVITED SPEAKERS:

R. HOLLIDAY (London)	R. RILEY (London)
P. HOLM (Copenhagen)	H. STERN (La Jolla)
B. C. LU (Guelph)	J. THOMAS (Cambridge)
J. L PETERSEN (Copenhagen)	L TRES (Chapel Hill)
S. W. RASMUSSEN (Copenhagen)	D. von WETTSTEIN (Copenhagen)
	D. ZICKLER (Orsay)

Participants are offered free dormitory accommodations and a limited number of fellowships for assistance with travel expenses are available.

Applications containing information on current research interest should be sent **before March 10, 1979** to

Professor D. von Wettstein
Carlsberg Laboratory, Gamle Carlsberg Vej 10
DK-2500 Copenhagen Valby, Denmark

8909(D)

SIMON FRASER UNIVERSITY

MASTER OF NATURAL RESOURCES MANAGEMENT PROGRAM

Applications are invited from biologists to join the newly-established Master of Natural Resources Management Program The position is a joint-appointment between the M R M Program and the Department of Biological Sciences Teaching responsibilities will include two graduate courses in the M R.M Program (1) population, community and ecosystem ecology, and (2) biological resources and resource management models, and courses in the Department of Biological Sciences Ph D required and research experience related to resource management preferable Appointment will be made at the Assistant/Associate Professor level Appointment effective July 1, 1979 Any appointee must be a Canadian citizen or eligible for landed immigrant status All appointments are subject to budgetary restraints

Please send applications accompanied by supporting documentation and names of three referees to Dr M. L. Barker, Acting Director, Master of Natural Resources Management Program, Faculty of Interdisciplinary Studies, Simon Fraser University, Burnaby, B C V5A 1S6 Deadline for applications January 31, 1979.

8868(A)

Under the sponsorship of the European Communities, the Department de Biologie Moléculaire of the Université Libre de Bruxelles is organizing an interdisciplinary training course to take place in Rhode-St -Genèse, from September 5 to 25, 1979 on

FIDELITY OF THE REPLICATION AND EXPRESSION OF GENETIC INFORMATION

Course directors M ERRERA and M RADMAN

The course will consist of 2 weeks of practical work during which each group will work on one of the following topics

1) Fidelity assays of translation with various ribosomal mutants
2) Codon-anticodon interactions
3) In vitro assays on accuracy of DNA synthesis without and with mutagenic treatments
4) Accuracy of in vivo DNA replication: mutagenicity assays with E. coli and phage λ
5) Chromosomal effects of carcinogens and malignant transformation

Every morning of the third week results of one group will be presented and discussed with all the course participants and with invited speakers who will lecture in the afternoons on subjects related to the morning's discussions (±2 lectures each afternoon)

The working language of the course will be English

Applications for enrolment should reach the Molecular Biology and Radiobiology Course Secretariat, Commission of the European Communities, DG XII, rue de la Loi 200, B-1049 Brussels, before 16 March 1979 and be accompanied by the applicant's personal history (stating knowledge of languages), a list of his scientific publications, a letter from the head of his laboratory and a justified order of preference for the five topics mentioned above.

Further information may be obtained from the same address

STUDENTSHIPS

THE QUEEN'S UNIVERSITY OF BELFAST

S.R.C. RESEARCH STUDENTSHIPS

The Science Research Council is likely to offer to suitable candidates a limited number of research studentships for 1979 tenable in the Faculties of Science or Applied Science and Technology; the former includes the Departments of Pure Mathematics, Applied Mathematics and Theoretical Physics, Chemistry (Analytical, Inorganic, Organic and Physical), Industrial Chemistry, Biochemistry, Zoology, Botany, Psychology, Archaeology and History and Philosophy of Science; the latter, Engineering Mathematics, Civil, Mechanical and Industrial, Electrical and Electronic and Aeronautical Engineering Departments.

The value of these will be in accordance with S.R.C. scales and students graduating in 1979 in Great Britain (and who are not resident in Northern Ireland) are invited to write stating their particular field of interest to the Dean of the selected Faculty by January 15, 1979. 8914(F)

FELLOWSHIPS

UNIVERSITY OF YORK

DEPARTMENT OF BIOLOGY

S.R.C. RESEARCH FELLOWSHIP

Applications are invited for a Postdoctoral Research Fellowship in collaboration with Dr J. Digby and Dr R. D. Firn. The work is on the control of the different growth which causes geocurvature and subsequent autotropic straightening of shoots. The candidate should have a background in plant physiology. A knowledge of German would be an advantage.

The position is tenable for three years and will be on the salary scale £3,883 to £4,382 (under review).

Three copies of applications, including the names of three referees, should be sent by February 15, 1979 to the Registrar, University of York, Heslington, York, Y01 5DD. Informal enquiries can be made to Dr Digby or Dr Firn, Department of Biology. Please quote reference number N/6095. 8872(E)

UNIVERSITY OF OXFORD

UNIVERSITY LECTURESHIP IN PSYCHOLOGY

TUTORIAL FELLOWSHIP AT ST ANNE'S COLLEGE

Applications are invited for the above post. Stipend according to age on the scale £3,883 to £8,257 per annum. Preference will be given to candidates with interests in the fields of Language and Communication, Cognition or Perception. The post may be held in association with a tutorial fellowship at St. Anne's College (open to men and women).

Further details may be obtained from the Acting Head, Department of Experimental Psychology, South Parks Road, Oxford OX1 3UD, to whom applications (two typed copies, one from overseas applicants) including the names of three referees should be sent by January 31, 1979. 8921(E)

UNIVERSITY OF SUSSEX

SCHOOL OF BIOLOGICAL SCIENCES

POSTDOCTORAL RESEARCH FELLOWSHIP IN BIOCHEMISTRY

Applications are invited for an M.R.C. financed Research Fellowship concerning studies of the rate of calcium and cyclic AMP in the release of growth hormone and corticotropin from the adenohypophysis. Previous experience in the field of isolated pituitary cells and/or biochemical endocrinology desirable. The fellowship is available from January 1, 1979 for one year in the first instance, extendable for a further eighteen months.

Salary in the range £3,883 to £4,882 per annum (under review) on the Research Fellow grade 1A scale.

Applications, including curriculum vitae, a list of publications if any, and the names of three referees, as soon as possible please to: Dr D. Schulster, School of Biological Sciences, University of Sussex, Falmer, Brighton BN1 9QG. 8891(E)

UNIVERSITY COLLEGE DUBLIN

DEPARTMENT OF HORTICULTURE

POSTDOCTORAL FELLOWSHIP

Applications are invited for a postdoctoral fellowship, sponsored by The National Board for Science and Technology, to study protein degradation and reutilisation in fruit trees and germinating seeds.

Applicants should have relevant research experience in the fields of horticulture, plant physiology or biochemistry.

The appointment will be for one year, initially, beginning in early 1979. The starting salary will be £3,762 per annum on an incremental scale.

Applications giving details of qualifications and experience and the names and addresses of two referees should be sent to:

Dr M. J. Hennerty,
Department of Horticulture,
University College,
Glasnevin,
Dublin, 9. 8932(E)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF PHYSIOLOGY

RESEARCH FELLOWSHIP IN EXPERIMENTAL NEUROLOGY

Applications are invited for a Research Fellow IA in the Department of Physiology. The Fellow will work on a five-year M.R.C. funded project involving the study of motor control in human subjects and other primates. Preference will be given to candidates with experience in either clinical neurology or neurophysiological research.

Salary will be on the research scale IA £3,883 to £6,555 (plus superannuation) according to age, qualifications and experience subject to maximum starting salary of £4,382.

Further details about the work may be obtained from Dr P. M. H. Rack, Department of Physiology, The Medical School.

Applications, three copies, with curriculum vitae should be sent to the Assistant Registrar, The Medical School, Birmingham B15 2TJ, by January 26, 1979. Please quote reference RF/PHY/478. 8918(E)

UMIST

CHAIRS IN CONTROL ENGINEERING AND IN APPLIED CONTROL ENGINEERING

The Chair in Control Engineering will be relinquished by Professor H. H. Rosenbrock, F.R.S., on December 31, 1978, to take up a S.R.C. Senior Fellowship. The Control Systems Centre, apart from a very small element of undergraduate service teaching, is essentially concerned with teaching and research at postgraduate level, but this pattern is not necessarily fixed for the future. The Institute recognises that the theoretical aspect of Control Engineering is heavily mathematically oriented, whilst the practical aspect is concerned with the many areas of application in industrial situations. The Control Systems Centre has so far concentrated on the middle ground, avoiding the more abstract theory and also avoiding too deep a commitment to applications. Effective links have been established with the Department of Mathematics to further the study of the theoretical aspects, and the Centre has also successfully collaborated with Engineering and other Departments in projects involving application. In recognition of the continuing development and expansion of the field the Institute has concluded that it should support two Chairs in this area. The Chair in Control Engineering will be filled by someone with an interest in theory, and a knowledge of practice.

The new Chair in Applied Control Engineering will be expected to develop further the existing active liaison with some of the Engineering and other Departments, and candidates should have wide experience in the applications of control to operations of industrial or commercial significance.

For both Chairs candidates are sought who have a firm commitment to research, who have proven teaching ability and who are capable of providing leadership and encouragement to the other members of staff, especially in research. By virtue of their scholarship and scientific interests they should be able to engender collaborative ventures with industry, government agencies, etc., and to command financial support from S.R.C., industry, etc.

Applications should be received as soon as possible after the appearance of this advertisement. Salary will be in the Professorial range with a minimum of £9,443 per annum (plus a cost of living increase still to be negotiated) and a further increase due in October 1979.

Further particulars and application forms may be obtained from the Registrar, UMIST, P.O. Box 88, Manchester M60 1QD, by quoting reference CSC/222/AI for Control Engineering and CSC/223/AI for Applied Control Engineering.

Informal enquiries may be made to the Registrar or to Professor H. H. Rosenbrock with a view to a preliminary informal visit. 8911(A)

ODENSE UNIVERSITY

Institute of Biochemistry

POSTDOCTORAL RESEARCH FELLOWSHIP

Lipid Biochemistry

Applications are invited for the above post for a maximum of three years to work in a research group engaged in studies of mammary gland lipid metabolism. The research fellowship has been granted to investigations on the role of intracellular fatty acid binding proteins in the regulation of fatty acid synthesis and development of methods for measurement of cellular acyl-CoA concentrations. Research experience in lipid metabolism, methods of lipid analysis and protein purification is desirable. The position is available immediately. Salary range: Danish kroner 7.856,36 to 12.998,59 per month plus bonus.

Further information can be obtained from Dr Jens Knudsen, Institute of Biochemistry, Odense University, Campusvej 55, 5230 Odense M, Denmark.

Applications should include a curriculum vitae and documentation of academic qualifications. Applications must be marked "stilling nr. 637" and should reach the Administration, Odense University, journalkontoret, Campusvej 55, 5230 Odense M, Denmark, not later than January 16, 1979. 8873(E)

June 11–16, 1979

Chloroplast membrane polypeptides

Organisers: R. J. Ellis (Coventry) and D. von Wettstein

This workshop is concerned with the functional characterisation, the biosynthesis and the genetics of chloroplast membrane polypeptides. Emphasis will be placed on comparing and coordinating efforts to separate and characterise the thylakoid polypeptides in organisms amenable to genetic analysis.

THE PARTICIPANTS WILL INCLUDE:

K. APEL (Freiburg)
C. ARNTZEN (Urbana)
P. BENNOUN (Paris)
R. J. BERZBORN (Bochum)
N. BISHOP (Corvallis)
P. BÖGER (Konstanz)
N.-H. CHUA (New York)
R. DOUCE (Grenoble)
N. GILLHAM (Durham)
J. GRAY (Cambridge)
K. W. HENNINGSEN (Copenhagen)
G. HØYER-HANSEN (Copenhagen)
C. J. LEAVER (Edinburgh)
O. MACHOLD (Gatersleben)
R. MALKIN (Berkeley)
B. LINDBERG MØLLER (Copenhagen)
N. NELSON (Haifa)
J. A. SCHIFF (Waltham)
G. H. SCHMID (Cadarache)
D. SIMPSON (Copenhagen)
J. P. THORNBER (Los Angeles)
L. P. VERNON (Provo)
K. WEGMAN (Tübingen)

The workship is intended for scientists actively working in this field. Applicatinns containing information on past and present research activity should be sent **before March 1, 1979** to

Professor D. von Wettstein
Carlsberg Laboratory, Gamle Carlsberg Vej 10
DK-2500 Copenhagen Valby, Denmark

THE CHARACTERIZATION OF CRYSTAL GROWTH DEFECTS BY X-RAY METHODS

29 AUGUST—9 SEPTEMBER, 1979
DURHAM, ENGLAND

A NATO Advanced Study Institute

(1) A survey of the various types of defects occurring in the different methods of crystal growth, the mechanism of their generation and their influence upon the properties of relatively perfect crystals.
(2) A detailed and advanced course in the observation and characterization of such defects by X-ray methods. The main emphasis will be on X-ray topographic methods but others will be included.

Applications to attend this Summer School should be made to reach Dr B. K. Tanner, Department of Physics, Durham University, Science Laboratories, South Road, DURHAM DH1 3LE, U.K. by January 31, 1979.

8897(D)

ASSISTANTSHIPS

QUEEN MARY COLLEGE

University of London
APPLIED MATHEMATICS DEPARTMENT

Applications are invited for a one-year

POSTDOCTORAL RESEARCH ASSISTANTSHIP

to begin not later than March 31, 1979, for work with Drs S. Simons and I. P. Williams on the optical properties of multicored interstellar grains.

Salary in range £4,359 to £5,342 per annum (including London Allowance).

Please apply by letter to the Registrar (N), Queen Mary College, Mile End Road, London E1 4NS, enclosing curriculum vitae and names and addresses of two referees.

8931(P)

UNIVERSITY COLLEGE LONDON

RESEARCH ASSISTANTSHIP

A short-term research assistantship is available in the Department of Zoology, starting in March 1979.

Applicants with experience of either cell electrophoresis or the production of hybridomas are invited to write to Professor N. A. Mitchison, University College London, Gower Street, London WC1E 6BT, before January 19, 1979.

8906(P)

ASSISTANTSHIPS (continued)

UNIVERSITY OF SOUTHAMPTON

SCHOOL OF BIOCHEMICAL AND PHYSIOLOGICAL SCIENCES

GRADUATE RESEARCH ASSISTANTSHIP

Applications are invited for appointment as a GRADUATE Research Assistant in the BIOCHEMISTRY GROUP of this School, to work with Dr D. P. Bloxham on the applications of thiosulphonate reagents to problems in protein structure and function. Applicants should have a good honours degree in biochemistry or chemistry and should have an interest in enzymology. The appointment, which is S.R.C. supported, will be made as soon as possible and is initially for one year, renewable for a further two years.

The salary will be within £3,884 to £4,883 per annum (under review) on Scale 1B for Research and Analogous Staff; U.S.S. benefits.

Applications giving date of birth, curriculum vitae and the names and addresses of two referees, should be sent to Mrs P. Vaughan-Smith, The University, Southampton SO9 5NH, by January 20, 1979, quoting reference 1043/R/Na.

8889(P)

UNIVERSITY OF DURHAM

DEPARTMENT OF CHEMISTRY

Applications are invited for chemists or chemical physicists for an S.R.C. Postdoctoral Senior Research Assistantship for 17 months from as soon as possible to work in collaboraton with Dr J. Yarwood on the interaction and dynamics of hydrogen bonded systems in the liquid phase. These studies which include infrared, far-infrared, Raman and neutron scattering studies are also supported by a N.A.T.O. research grant and would be carried out at Durham, the Technical University, Braunschweig and at A.E.R.E. Harwell. Some experience in one branch of molecular spectroscopy is essential and an interest in the chemical physics of molecular motions and interactions in the liquid phase would be at advantage.

Initial salary £3,883 or £4,133 per annum on National Research Range 1A plus superannuation.

Applications (three copies) naming three academic referees should be sent by January 22, 1979, to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE.

8904(A)

UNIVERSITY OF DURHAM

DEPARTMENT OF APPLIED PHYSICS AND ELECTRONICS

Applications are invited for an S.R.C.

POSTDOCTORAL RESEARCH ASSISTANTSHIP

tenable for three years from early 1979. Applicants should have qualifications in physics, materials science, electronics or a related subject.

The successful applicant will work on Electroluminescence in Zinc Sulphide in the group directed by Dr J. Woods, and will be concerned with the fabrication and evaluation of light emitting diodes and larger area devices.

Initial salary £3,883 or £4,133 per annum on National Research Range 1A, plus superannuation.

Applications (three copies) naming three referees, should be sent by January 8, 1979, to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained.

8878(P)

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF APPLIED BIOCHEMISTRY AND NUTRITION
FOOD SCIENCE LABORATORIES

A.R.C. RESEARCH ASSISTANTSHIP

tenable from January 1979.

Applications are invited for the post to study the dynamics of starch gelatinisation using one or more novel physicochemical techniques. Candidates may register for a Ph.D. degree but should preferably have a good honours degree in Chemistry, Physics or some related subject.

Salary £3,384 to £3,883.

Applications, naming two referees, should be sent as soon as possible to: J. M. V. Blanshard, Department of Applied Biochemistry and Nutrition, University of Nottingham, School of Agriculture, Sutton Bonington, Loughborough, Leics. LE12 5RD, from whom further details may be obtained.

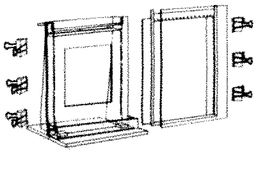
BRL Electrophoresis Systems



SEQUENCING GEL ELECTROPHORESIS SYSTEM

- Direct buffer — gel contact eliminates paper wicks
- Unique gasket system eliminates grease and clay seals
- Comb and spacer sets for 0.4, 0.7, 1.5 mm gels
- Design eliminates need for fragile notched glass plates
- Fully warranted for 90 days
- cat. no. 1030—$350

BRL Acrylamide—BRL Agarose

INTRODUCTORY OFFER—
NOW THROUGH FEBRUARY 28, 1978

Purchase a SEQUENCING Gel Electrophoresis System and receive 100 grams of BRL Acrylamide with our compliments.

—ALSO—

Purchase a BRL HORIZONTAL Gel Electrophoresis System and receive 100 grams of BRL Agarose with our compliments. **To order:**

BRL Bethesda Research Laboratories, Inc.
411 N. Stonestreet Avenue, Rockville, Maryland 20850
